APPROACH: Studies will be made of pesticide pollution of farmstead domestic water supplies and to identify sources and routes of contamination. The relation of susceptibility of water supplies to pesticide contamination with susceptibility to other contaminants such as bacteria or nitrate will be determined. Studies will be made of well construction techniques to determine level of protection needed to eliminate pesticide contamination. Determination will be made of the performance of pesticide removal equipment, devices and techniques to effect a safe economical water supply. Investigations will be conducted to outline the requirements for a disposal system for waste water collected from the cleaning of application equipment or from the disposal of excess persistent pesticides.

PROGRESS: Continued investigation of a shallow, bored well contaminated from a non-leached source with DDT and Toxaphene shows little change in contamination level after 3 years' observation. Pesticide level in the water remains stable (DDT less than ppb, Toxaphene few ppb) while levels in well sediment remain in the high ppm range. Level of contaminants in soil surrounding the well is generally lower than was the level during the previous year. Soil samples taken in increments of 4 inches indicate levels of several ppm in the surface 4 inches while only low ppb levels are found below 4 inches. Two commercially available charcoal filters were dependent on the flow rate when evaluated for the removal of lindane (low ppm range) from water. Removal efficiency varied from approximately 75 percent at 1 GPM to approximately 30 percent at 5 GPM. Water from 27 local wells was sampled for bacterial contamination and nitrate level. Approximately 30 percent exceeded the permissible nitrate level of 10 ppm NO(3)-N. Maximum NO(3)-N measured nearly 50 ppm.

4.0027, PESTICIDE MOBILITY AND DEGRADATION IN SOIL-WATER SYSTEMS

R.E. GREEN, Univ. of Hawaii, Agricultural Experiment Sta., *Honolulu, Hawaii* 96822 (HAW00141)

OBJECTIVE: Identify and characterize the physical-chemical properties of the pesticide-soil-water system; develop mathematical model(s) which will provide semi-quantitative prediction of pesticide movement in soil-water systems; measure pesticide transport through and over soil in the field or in lysimeters.

APPROACH: The kinetics of adsorption-desorption reactions of carboxylic acid herbicides will be studied using selected soils; a mathematical model will be developed which will describe the effects of pesticide adsorption, degradation and hydrodynamic dispersion using available input data; movement of picloram with infiltrating water will be studied under field conditions on the Molokai soil.

PROGRESS: (1) Adsorption isotherms for four s-triazine herbicides which are important to Hawaiian agriculture were measured on four soils having a wide range of organic matter contents and different mineralogies. The relative magnitudes of adsorption were nearly the same on all soils: ametryne, sumatol (GS-14254), atrazine, simazine. Soil acidity and O.M. content are both positively related to triazine adsorption. (2) A procedure was developed to allow determination of the distribution of triazines between adsorbed and solution phases as hydrolysis proceeded. Distribution coefficients for atrazine increased several fold during a 60-day period; this implies decreased mobility of the residual parent compound. (3) An adsorption method, consisting of continuous flow equilibration of soil with a pesticide solution followed by sebsequent displacement with an appropriate organic solvent was developed and tested with two herbicides (atrazine and diuron) on four soils. This method provided high precision on all adsorbents, avoided destruction of aggregates, and was useful in measuring adsorption reversibility.

SUPPORTED BY U.S. Dept. of Agriculture

4.0028, PESTICIDE MONITORING PROGRAM LAKE MICHIGAN

B.J. LELAND, State Dept. of Pub. Instruct., *Springfield, Illinois* 62706

A pesticide monitoring project involving Lake Michigan and tributaries in Illinois is proposed as part of the Four State Enforcement Conference. The prime objective is to determine whether substantial amounts of persistent chlorinated hydrocarbon insecticides are reaching the Lake. A second objective is to evaluate present levels of residue in sediments and in organisms representing the aquatic food- chain.

Since herbivorous organisms within streams consume large quantities of periphyton and since persistent insecticides are cumulative, the levels found within periphyton (algae) to a large extent dertermine the levels found in organisms higher in the food chain. Fresh-water mussels may be useful detectors of slug discharges. They are practically immobile organisms which pump large volumes of water and feed upon the particulate matter. Minor changes as well as major changes within different sections of the stream would be revealed in body tissue of the clams. An evaluation of levels of insecticides found within sediments is part of the monitoring program. Insecticide analyses will be performed on the whole bodies of fish native to the location.

All sampling will be in the eastern portion of Lake County, Illinois and along the shore line of Lake Michigan in Lake County. Analyses will be made in the Diagnostic Laboratory of the Illinois Department of Public Health at Chicago.

4.0029, THE FATE OF SELECT PESTICIDES IN THE AQUATIC ENVIRONMENT

G. SPRUGEL, State Natural History Survey, *Urbana, Illinois* 61801

Objectives: 1. To conduct laboratory and field investigations with methoxychlor, diazinon, and Furadan, to analyze the long- and short- term, subtle, direct, and chain reaction responses of these pesticides in the living and non-living constituents of the aquatic environment. 2. To develop and improve analytical and biological techniques and methodology essential to investigations on the disposition and fate of pesticides in the aquatic environment.

The objectives were developed on two assumptions, namely, that pesticides either directly or indirectly enter the aquatic environment and that the future use of pesticides is dependent in part upon the action of these chemicals in the aquatic environment. The research proposed and the plan of operation will involve a team approach by entomologists, aquatic biologists, chemists, and consultants expert in the taxonomy of aquatic organisms, environmental biology and toxicology.

The plan of procedure will utilize simple food chains already existing in our laboratory, such as filamentous algae to Tilapia and filamentous algae to tadpoles to large-mouth bass, but the movement, disposition, and ultimate fate of the insecticides and their metabolites will be determined in non-living components such as clays, silts, and debris as well as living components of experimental aquatic systems. Field tests will utilize lysimeters and artificial and natural release into manipulated and natural aquatic systems and ponds in the field. Radioisotopes will be used to trace movement and in some instance the metabolic pathways in the living organisms.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

4.0030, CONSTRUCTION OF PESTICIDES DEGRADABLE BY NORMAL MICROFLORA OF NATURAL WATERS AND SOILS

R.E. KALLIO, Univ. of Illinois, School of Life Sciences, *Urbana, Illinois* 61801

It is proposed to establish the amount of substitution, halogen or other substituent group, which can be appended to aromatic rings and still leave them degradable by normal microflora in natural waters and soils. An analysis of the kinds of microorganisms capable of degrading such substituted aromatic rings will be undertaken and it will be established whether the enzymes required for the degradation are inducible. Such induced enzyme systems will be studied to see whether their range of aromatic ring cleavage potentials are greater than simply rupturing the ring of the inducer substrate. These data will be correlated with the ground rules required for pesticide (insect or plant) toxicities. Synthesis of molecules containing an inducer, as well as a pesticide active moiety, will be undertaken and tested in the enzyme system.

SUPPORTED BY University of Illinois

4.0031, RESEARCH INITIATION - FATE OF SELECTED ORGANOPHOSPHATE AND CARBAMATE INSECTICIDES IN SURFACE WATERS

H.V. LELAND, Univ. of Illinois, School of Engineering, *Urbana, Illinois* 61801

The objective of this study is to evaluate ecological effects associated with the use of several insecticides currently recommended as suitable replacements for the more persistent chlorinated hydrocarbon compounds. The degree of persistence and biological concentration of selected organophosphate and carbamate residues in water will be determined at experimental inpoundments. Known amounts of insecticides will be applied under normal operating conditions at prescibed application rates. The toxicity of stable residues to vertebrate and invertebrate aquatic species will be determined by continuous-flow bioassays. Pathways of degradation and persistence of metabolites in these species will be examined using radiolabelled insecticides. Heterocylic compounds are ring-labelled to permit concurrent evaluations of the pathways of metabolism of the insecticide and the stable products of hydrolysis. This project will assist in the development of sound practices relating to the use of insecticides near lakes and streams and will assist in the establishment of water quality criteria for these insecticides.

SUPPORTED BY U.S. National Science Foundation

4.0032, BIOCHEMISTRY OF HERBICIDE ACTION

F.W. SLIFE, Univ. of Illinois, Agricultural Experiment Sta., *Urbana, Illinois* 61801 (ILLU-15-0389)

OBJECTIVE: Study the penetration, translocation, and degradation of herbicides and plant growth regulators in plants; study the effect of these applied compounds on the physiology of plant cells and determine if these effects are related to changes in the particulate matter; study the fate of these compounds in soild and determine their possible contribution to pollution of our water supplies.

APPROACH: Labeled herbicides and plant growth regulators will be used to study penetration, rate of degradation and ultimate fate of the applied compounds. In addition labeled compounds will be used to determine what particular part of the Cell cytoplasm reacts with the applied compounds. This should give valuable leads to the exact mode of action. Field and laboratory procedures will be used to determine, leachable, rate of degradation, and effect of soil applied compounds on soil life.

PROGRESS: Penetration, translocation, and degradation of 2,4-D was studied in climbing milkweed (Ampelamus albidus). Although penetration was low, degradation was also low allowing excellent translocation to meristematic areas and the root system. In approximately 72 hours after 2,4-D application, nucleotide exudation from the root system indicated increased membrane permeability. This suggests that in perennial weeds, the cause of death from 2,4-D is disfunction of the root system. The degradation of atrazine in corn was studied under different environmental conditions. Both the enzymatic and non-enzymatic degradation processes were functional under cold wet conditions, but at a reduced level over corn grown under normal conditions. In addition, the rapid genetration of atrazine into corn grown under cold wet conditions contributed to overloading the detoxification mechanisms and thus severely injured corn. Butylate vapors stimulated germination of grass weed seeds. This herbicide appears to effect dormancy of semi- dormant seeds. Ca adsorption by roots of Cocklebur increased after 2,4-D application to the foliage. It reached a peak in 30 minutes and at 60 minutes retreated to the level of control plants.

SUPPORTED BY U.S. Dept. of Agriculture

4.0033, MONITORING AND ASSAY OF PHYTOTOXIC AIRBORNE PESTICIDES AND VOLATILE POLLUTANTS

C.H. SHERWOOD, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010 (IOW01625)

OBJECTIVE: Monitor representative areas in Iowa for content of pollutants. Identify unknown pollutants that are injurious to plants and other organisms. Determine movement of pollutant pesticide volatiles and aerosols singly and in combination as affected by various environmental conditions. Investigate thresholds of injury regarding pesticide concentration, stage of plant growth, plant maturation, and combinations of pollutants. Chart seasonal plant growth risk areas in Iowa communities.

APPROACH: Collect air samples, plant materials and climatological data. Samples will be assayed (biological and chemical). Movement of pollutants will be determined by tagged pesticides. Meterological factors effecting dispersal of airborne pollutants will be determined. Histological studies will be conducted.

PROGRESS: Detection, evaluation and documentation including photographs accomplished for 2,4-D, representative horticultural plants given controlled exposures. Exposure chambers contaminated with 2,4-D were found permanently contaminated in that solvents, acids, bases and heat plus O(3) and 70 C were inadequate for decontamination. Except for O(3) plus 2,4-D interactions reducing effects of 2,4-D dramatically, combined effects of other pollutants tended to be slightly less than simple additives of the effects as caused by exposures to a single pollutant. Synergistic effect of O(3) plus SO(2) not found. Air sampling by instrumentation at ground level and at 15m height detected 2,4-D, DDE, etc. In rain samples, dieldrin, kelthane & endrin were most common pesticides found. Monitoring limited primarily to Iowa State University campus and Horticulture Farm with good success in respect to 2,4-D and other volatile pollutants. Exposure trials demonstrated interference effect of some pollutants and lack of synergism generally. Also lack of cancelling out of NH(3) and SO(2) exposed simultaneously. Thresholds of injury (minimum for visible symptoms) determined for representative pollutants and horticultural plants. Risks through season not completed but peak amounts of pollutants appeared intermittently throughout the growing season.

SUPPORTED BY U.S. Dept. of Agriculture

4.0034, REMOVAL OF CONTAMINANTS FROM RURAL WATER SUPPLIES

C.T. HAAN, Univ. of Kentucky, Agricultural Experiment Sta., *Lexington, Kentucky* 40506 (KY00114)

OBJECTIVE: Determine extent and state in which pesticides occur in farm water supplies; evaluate effectiveness of presently recommended farmstead treatment systems in removing pesticide residues; investigate possible application of new techniques and system arrangements to remove pesticide residues from rural water supplies.

APPROACH: Selected farm water supplies will be tested using standard chemical analysis techniques to ascertain the degree of pesticide contamination in these locations. Results will be correlated to the pesticide history of the watershed. The effectiveness of conventional rural water treatment and filtering methods in removing different pesticides will be studied. New or potential methods of removing pesticide residues from water supplies will be studied and evaluated for possible application on the farmstead.

PROGRESS: Twelve fallow plots 3.81 feet square were treated with Aldrin, Dieldrin, and DDT. After waiting for various periods of time (15 minutes, 1 day and 3 days), artificial rainfall was applied. The runoff water, eroded sediments, and soil remaining on the plots were then analyzed to determine the concentration of the three pesticides. At this time the data analysis is incomplete.

4. PESTICIDES

SUPPORTED BY U.S. Dept. of Agriculture

4.0035, ENGINEERING SYSTEMS FOR COTTON PRODUCTION

B.J. COCHRAN, Louisiana State University, Agricultural Experiment Sta., *Baton Rouge, Louisiana* 70803 (LAB00858)

OBJECTIVE: Develop or improve cotton production subsystems while simultaneously providing information and data for a computer simulation model of the cotton production system.

APPROACH: Determine physical properties of weeds and cotton plants that influence heat transfer into the plants. Determine the characteristics of flame required to obtain optimum heat application for maximum weed control. Develop new and improved conventional methods to obtain maximum weed control by the utilization of extended heat exposure, electrical power, vibrations and other sources. Determine the energy required to obtain the optimum conditions for maximum weed control and incorporate the results into the regional model cotton production system.

PROGRESS: Twenty-nine new premergence herbicide treatments were analyzed for selectivity. None of these were added to the list of recommended herbicides, although seven will be retained for further study. Further tests appear to substantiate earlier conclusions that combined preplant and preemergence treatments are somewhat more effective than either single treatment. Both treatments may be necessary for controlled heavy infestations or broad spectra. Experiments indicate that using foam as a carrier of preemergence herbicides offers no benefit other than reduction of the drift, although foam alone may prove to be a valuable post emergence herbicide due to probable substantial temperature increases under the foam. Use of foam as a perishable sealant over injected methyl bromide gel gave excellent weed control as well as control of soil borne organisms. Nineteen treatments, including the common ureas, MSMA plus urea, and two experimental herbicides were included in a uniform post emergence experiment. Excellent results were obtained on a broad spectrum of weeds with all combinations of a urea plus MSMA, the superior treatments being diuron or fluometuron plus MSMA. No significant interactions were observed among herbicides, fungicides, and insecticides with combinations of a fungicide (Demosan), an insecticide (Thimet), and three herbicides (diuron, fluometuron, and norea).

SUPPORTED BY U.S. Dept. of Agriculture

4.0036, WATER AND SOIL POLLUTION BY FARM CHEMICALS IN THE LOWER MISSISSIPPI DELTA

C.H. WILLIS, Louisiana State University, U.S.D.A. Soil & Wa. Cons. Div., *Baton Rouge, Louisiana* 70803 (SWC-024-BBR-3)

OBJECTIVE: Determine the mechanism for and extent of movement of pesticides, plant nutrients and other pollutants over and through the soil in drainage water and develop methods for alleviating the effects of pollutants on water and soil resoruces.

APPROACH: Extent and mechanism of movement of pollutants in surface and subsurface drainage water will be measured in the laboratory and on field plots. Measurement systems will be developed for enhancing chemical or biological degradation and immobilization, and disposal of the polluting materials in soil and water.

PROGRESS: Where endrin was applied to sugar cane for borer control on very dry Mhoon clay loam at Baton Rouge, Louisiana, the concentration in surface drainage water was 1.06 and 0.46 ppb when rain followed the application in 24 and 72 hours, respectively. Concentrations in tile effluent of 0.45 and 0.07 ppb from rains 24 to 72 hours after rain were attributed to the flow of water through cracks in the soil instead of by true percolation to the tile. Endrin found in the soil 6 months after application was 65 and 24 ppb, respectively, where rains came 24 and 72 hours after application. This difference probably was due to the loss by volatilization of the pesticide with the variation in exposure to temperature and other weather phenomena before rain fell. All these results confirm similar findings in 1967 and 1968, and suggest that pesticide content of soil and water will be lessened if the material is applied as long as possible before rain occurs. A method was developed at Baton Rouge, Louisiana for detecting losses by volatilization of pesticides applied to the soil. Preliminary results of studies underway indicate that flooding the soil retarded the volatilization of DDT and DDD, suggesting that this treatment might be used to reduce the atmospheric pollution potential of a pesticide-treated soil.

SUPPORTED BY U.S. Dept. of Agriculture

4.0037, PESTICIDE POLLUTION OF FARMSTEAD WATER SUPPLIES IN THE NORTHEAST

E.R. JONES, U.S. Dept. of Agriculture, Agricultural Engin. Res. Div., *Beltsville, Maryland* 20705 (901-032-B605)

OBJECTIVE: Develop methods for preventing pesticide contamination of farmstead water supply systems.

APPROACH: Determine design characteristics for farmstead water well construction which will reduce the possibility of pesticide contamination. These studies will include investigations of selected cases of pesticide contamination to learn means of entry, concentration and persistence of contamination. Develop equipment and/or procedures to eliminate or reduce the risk of pesticides entering the system by backsiphonage or cross-connections. Develop methods and techniques for using, handling and storing of pesticides which will eliminate the threat of contamination of the water system. This will include studies of the pesticide equipment servicing area where filling, overflow, spillage, leakage, drainage and washing practices may influence the incidence of pesticide contamination.

PROGRESS: Sediment removed from the bottom of well WA10A contained dead insects, macerated straw, and a greasy substance. By error these were discarded. The sediment was allowed to settle for 48 hours and samples taken of sediment and supernate. The results of analysis were sediment dry weight 1000.0 ppb sulfur, 40.0 ppb DDT, supernate 0.05 ppb DDT. The concentration in the supernate was similar to a water sample obtained 42 days earlier, 0.04 ppb DDT. The ratio of DDT in sediment to supernate of 800:1 is similar to values for surface water. The affinity of free DDT in water for the air water interface and volatilization by codistillation make it quite certain that the major avenue for penetration of chlorinated hydrocarbons below the water table is inadequately protected wells. Concentrations found in contaminated well water are normally less than that reported for rain water. Research well WA10B was constructed 113 feet south of Washington County, Maryland sample well WA10A. The technique used, if further developed and adopted, may reduce the cost of the cased portion of the well 50%. Present costs encourage inadequate depth of casing and grouting. Well WA10B produces water of more uniform quality than well WA10A. Collecting samples after heavy rainfall in Wicomico County resulted in an increase of confirmed pesticide concentrations.

4.0039, MECHANISMS OF PESTICIDE ACCUMULATION IN AQUATIC ORGANISMS

R. REINERT, U.S. Dept. of Commerce, Natl. Marine Fisheries Service, *Ann Arbor, Michigan* 48107

A laboratory program designed to compare the relative importance which direct uptake of insecticides from water and biological magnification via the food chain have on the buildup of chlorinated hydrocarbon insecticides in aquatic communities.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

4.0040, THE INFLUENCE OF HERBICIDES USED ON HORTICULTURAL CROPS ON STREAM ECOLOGY

G.S. HOWELL, Michigan State University, School of Agriculture, *East Lansing, Michigan* 48823

The proposed research would involve a two-fold study of the effect of herbicides commonly applied to horticultural crops on the ecology of microflora in streams adjacent to the orchard or field. The laboratory phase of the research includes application of herbicides to water samples collected from a stream. Subsequently, measurements of the growth, development and population dynamics of the natural microflora will be made. Growth will be measured via dry weight determinations, quantitative estimation of chlorophyll A, and measurement of photosynthesis and respiration via illuminated manometric techniques. The effect of herbicide application on algal population dynamics will also be measured via per cent estimatation of population components.

The field phase of the research will involve the collection of water samples from streams prior to, during, and after the stream passes an orchard or field. Oceana County, in western Michigan, is proposed as the site for the field work based on two criteria: 1) it is an important fruit production area, using large amounts of herbicides, 2) it has a stream offering two methods sampling. Consecutive sampling in the same stream and comparison sampling between two independent watersheds. One of which drains a fruit area while the other drains a non-cropped area.

Water samples will be collected and concentrated by flash evaporation and analyzed for the following parameters: a. herbicide residues via chloroform extraction and measurement by gas-liquid chromatography. b. total N, by micro-kjeldahl procedures. c. ND sub 3 and other nutrient elements of spectrographic analysis. d. total dry matter.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

4.0041, BIOCHEMICAL ECOLOGICAL RELATIONSHIPS OF PESTICIDES AND THE BIO-CONSTITUENTS OF AQUATIC COMMUNITIES

N.R. KEVERN, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00940)

OBJECTIVE: Evaluate amount, storage, build-up and releases of pesticides under varying biological and chemical-conditions.

APPROACH: Studies on contamination and levels necessary to produce injury, debility, sterility or mortality will be conducted. The physiological effects of pesticides on energy exchange measured at the cellular level. Direct bioassay and gas chromatography employed to monitor the accumulation of pesticides in aquatic systems. Determine site of damage and identification of effects of detergents, metallic ions, BOD and other chemicals. Rate of transfer, buildup and exchange within the biota of aquatic systmes will be determined.

PROGRESS: The sub-project under this study that has been emphasized this past year dealt with the downstream movement of invertebrate organisms in streams. The nocturnal nature of this movement has been documented in the literature for very small streams. Sampling problems in large streams must be understood before data can have a quantitative meaning. Thus, in order to relate transport of pesticides or other elements via downstream drift, it is necessary to quantify the drift. The purpose of this study was to measure the rate of drift in three contrasting streams and determine what relationship exists between drift rate and degree of enrichment. Additionally an attempt was made to determine how drift is related to current velocity. The three streams chosen for this study were the Jordan River in Antrim County, AuSable River in Crawford County, and Red Cedar River in Ingham County. Two 24-hour series of drift samples were collected in each stream. Samples of benthic invertebrates were collected following each 24-hour drift collecting period. To investigate the relationship of current velocity to drift rate, five series of samples were collected along a transect across the stream at three points where the velocity was different. Although standing crop estimates did not reflect the degree of enrichment in the streams, total drift measurements showed a relationship to enrichment. The relationship between total drift and current velocity was linear, as expected. However, the drift rate of Baetis sp. (may flies) and Simulium sp. (black flies) appeared to be influenced by behavioral as well as physical factors and was therefore non-linear. Methods for sampling drift are discussed with suggestions for standardization of technique.

SUPPORTED BY U.S. Dept. of Agriculture

4.0042, PESTICIDE MONITORING OF AQUATIC ENVIRONMENT, MICHIGAN PORTION OF THE GREAT LAKES BASIN

C.M. FETTEROLF, State Bur. of Water Management, *Lansing, Michigan* 48926

Insecticides have been identified as causing problems with reproduction of gulls and raptorial birds in the Michigan portion of the Great Lakes Basin, as well as causing reduction hatchery reproductive success of coho salmon, and by accumulating above FDA tolerances in fish. Objective of this program is to identify the levels of pesticides in tributary streams to the Great Lakes from the State of Michigan, to identify the sources so they may be controlled, and to establish residue backgrounds against which to judge the success of control programs.

Water samples are collected monthly from the mouths of major tributaries to the Michigan portions of the Great Lakes and analyzed by gas chromatography for several insecticides. Freshwater mussels are held in cages for 3-4 week periods near the mouths in the major tributaries and in 60 minor tributaries and then analyzed for several insecticides. This exposure period permits them to accumulate insecticides to measurable concentrations. Stream sediments are also analyzed periodically. As major pesticide-contributing water courses are identified, sampling fans out into the interior to the sources.

Spot sampling is conducted at municipal and industrial wastewater sources and in addition municipal water supplies are checked periodically. Similar programs are underway in Ill., Ind., Minn., And Wisc.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

4.0043, PRESTICIDE INPUTS AND LEVELS IN MINNESOTA WATERS OF THE LAKE SUPERIOR BASIN

T.A. OLSON, Univ. of Minnesota, School of Public Health, *Minneapolis, Minnesota* 55455

The continued use of persistent insecticides in the Great Lakes System constitutes a potential threat to that Ecosystem and ultimately to the welfare and well-being of man. One of the first steps which must be taken if this hazard is to be met and brought under control is the accurate identification of the sources and avenues of entry which characterize each pesticide. The proposed study of Minnesota Waters of Lake Superior will therefore deal with current pesticide levels in streams along the North Shore of Lake Superior and is designed to determine the importance of these streams and their respective watersheds as sources of insecticide pollution. Captive, living fresh- water clams or other suitable organisms, which can take up and store insecticides, will be employed as concentrators in certain streams. A Water monitoring program which complements the test with living organisms, will be directed toward the major tributaries and will consist of samples collected on a scheduled basis, in some instances over a three day period. The north shore area, with its streams, from Duluth to the Canadian boundary, is to be included in the study.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

4.0044, A STUDY ON THE FEASIBILITY OF LOW VOLUME APPLICATION OF INSECTICIDES FOR CONTROL OF COTTON INSECTS

M.H. ADAIR, Mississippi St. University, Agricultural Experiment Sta., *State College, Mississippi* 39762 (MIS-3-206-1034)

OBJECTIVE: Determine the most effective swath width to be delivered by the low volume application technique and the distribution of droplets to obtain adequate control of cotton pests. Evaluate the effectiveness of the low volume formulations against cotton pests as compared with the conventional formulations.

Determine the relative drift problem with low volume concentrates compared with water diluted formulations. Evaluate low volume ground application equipment for coverage, efficiency, and effectiveness in controlling cotton pests.

APPROACH: Establish sampling stations using oil sensitive dyed cards across swaths to access spray patterns. Make natural infestation counts and bioassay treatments to evaluate materials. Establish indicator cards outside swath to determine amount and distance of drift. Set up indicator cards in the same manner for evaluating low volume ground machinery.

PROGRESS: During 1968 tests were conducted to evaluate the aerial application of ULV formulations of insecticides for control of pests on cotton. The studies were designed to compare the relative effectiveness of ULV materials when applied at different rates and at approximately the same droplet size using the Micronair system. Strobane T-methyl parathion was applied at a full rate (2-.5 lbs./acre), a 1/2 rate (1-.25 lbs./acre) and a 1/4 rate (.5-.1 lbs./acre). These ULV rates were compared with the same material as a standard emulsifiable concentrate. Results showed that all treatments gave good control, however, the infestation pressure was generally too low for a good evaluation. The different rates of Strobane T-methyl parathion compared favorably with the conventional treatment. There also appeared to be no outstanding difference in control among the various rates. The conventional treatment and the ULV treatments including the low rate of Strobane T- methyl parathion performed equally well.

SUPPORTED BY U.S. Dept. of Agriculture

4.0045, EVALUATION OF LOW VOLUME CONCENTRATE FORMULATIONS OF INSECTICIDES FOR CONTROL OF COTTON INSECTS

M.H. ADAIR, Mississippi St. University, Agricultural Experiment Sta., *State College, Mississippi* 39762 (MIS-8-240-1066)

OBJECTIVE: Determine the optimum droplet size of ultra low volume (ULV) insecticides for control of cotton pests. Evaluate aerial and ground application equipment for control of droplet size, drift control, and insect control. Compare with conventional systems and formulations. Determine most effective swath widths for ULV aerial and ground equipment.

APPROACH: Insecticides will be applied to potted plants and small field plots with a tractor-type spinning disc applicator. The disc speed will be varied to give a range of droplet sizes. Treated plants will be used to bioassay various cotton pests. Aerial equipment will be evaluated for efficiency in control of droplet size and of efficiency of application to the target area. Measurements will consist of bioassay of natural pest populations, counts of droplets deposited, and chemical analyses of deposits in the target area. The effective swath width will be determined in these same tests by recording the deposit across the plots and by bioassay with the field population of pests.

PROGRESS: Aerial conventional low volume and ultra low volume application of methyl parathion indicated a wider swath potential (80- ft) for ULV as compared to conventional LV (40-ft). Based on the wide 80-ft swath for ULV and the 40-ft swath for LV the percent recovery in the swath for both methods of application was comparable. More ULV applied methyl parathion impacted on the ground downwind of the swath. Droplet diameter of ULV droplets impinging on oil sensitive cards ranged from 54 to 138 microns. A comparison of aerial ULV application with Micronair, aerial ULV application with a boom and aerial conventional LV application with a Micronair using a Toxaphene-methyl parathion insecticide mixture indicated no differences in Heliothis control among the different methods of application.

SUPPORTED BY U.S. Dept. of Agriculture

4.0046, DISPOSING OF SURPLUS PESTICIDES AND PESTICIDE CONTAINERS

B.J. STOJANOVIC, Mississippi St. University, Agricultural Experiment Sta., *State College, Mississippi* 39762 (901-062-AE-CR-1(GR))

OBJECTIVE: Determine the combustion temperatures and the volatile products of selected pesticides. Investigate the use of chemicals and other materials as aids in the decomposition of pesticides and containers. Investigate the use of indigenous soil microflora as an aid in the decomposition of pesticides in soils. Determine the requirements for pesticide containers that are readily combustible. Develop specifications for an incinerator or other device for the disposal of pesticides and containers.

APPROACH: Three general avenues of approach will be followed in the investigations concerning decontamination and safe disposal of selected pesticides, their formulations and pesticide containers: combustion, treatment with chemicals, and exposure to microbial activity in soils. This project is cooperative with CR No.0710-01-32-(Gr. (Accession No. 0017430).

PROGRESS: Incineration of pesticide standards and formulations at 900 C. in air, produced hazardous gases such as hydrogen chloride, chlorine, hydrogen sulfide, nitric oxide and ammonia, whereas the ashes of wettable powders of dalapon, diuron, and zineb contained bromine, arsenic and zinc among other elements. Combustible containers and container closures, burned singly or mixed, were completely incinerated between 550 and 700 C. Aluminum, calcium, iodine, paladium, silicon, sulfur, titanium, and zinc were found in the container ash. Of several chemicals evaluated for pesticides decontamination, 70% calcium hypochlorite substantially degraded dicamba, diuron, DNBP, and 2,4-D. Low temperature heating (200 to 400 C.) partially degraded pesticides to chemically simpler, less toxic materials. Most pesticides applied at the rate of 5 tons of active ingredient per acre to a calcareous soil resisted microbial degradation. Also most pesticides depressed soil bacteria but favored streptomyces. Numbers of fungi were either increased, decreased, or eradicated (by DNBP and PMA). Surveys in Mississippi indicated that users destroy most of the empty glass, plastic and paper pesticide containers by burning. Metal containers were either stored, sold, left in city or farm dump or thrown in stream. A small scale model incinerator was designed and constructed for use in the laboratory testing, and a packed tower was selected for preliminary scrubbing of off-gases.

SUPPORTED BY U.S. Dept. of Agriculture

4.0047, PRECISE PLACEMENT AND DRIFT CONTROL OF INSECTICIDE AND PESTICIDES WHEN ULTRA-LOW VOLUMES

E.D. THREADGILL, Mississippi St. University, Agricultural Experiment Sta., *State College, Mississippi* 39762 (MIS-8-240-0387)

OBJECTIVE: Establish fundamental relationship for predicting microparticle behavior in complex flow fields. Determine optimum placement methods and patterns for ultra-low volume chemical applications. Translate the results of objectives A and B into a practical technology for development of methods and machines for ultra- low volume applications of chemicals.

APPROACH: The project is concerned with the effect of thermal, gravitational, inertial, aerodynamic factors on particle placement and deposition. Recent developments in the fields of aerosol mechanics and particle dynamics will be used in order to determine the influence of vortices, air turbulence, and plant micro-environment on particle movement. The results obtained from the previous investigations will be used to develop methods for imparting energy to spray particles in complex flow fields. Design criteria and specifications for equipment needed in ultra-low volume applications will be developed.

PROGRESS: A model wind tunnel for controlling wind velocity, wind velocity profile, temperature gradient and turbulence intensity has been constructed and tested. Results verified the feasibility of constructing a prototype, which is nearing completion. Through cooperative research with the USDA Boll Weevil Research Laboratory, data concerning the effect of wind speed, turbulence, temperature gradient and relative humidity on the drift controlled size drops of liquids having different physical properties have been collected and are being analyzed. These liquids were applied with ground equipment. Through cooperative research with the Departments of Entomology and Biochemistry, the influence of wind speed, temperature, relative humidity, and application rate on the drift of uncontrolled size drops of aerially applied methyl parathion has been determined. These data, and additional data to be collected by spraying controlled size drops in the wind tunnel, will be used to evaluate the previously developed mathematical model. A device for aerially applying controlled size drops has been constructed and will be

evaluated. A study of motion of controlled size drops within the plant canopy and the deposition of these drops on plant surfaces has been initiated. Liquids having varying physical properties will be used. The drops will be subjected to various atmospheric conditions in the wind tunnel.

SUPPORTED BY U.S. Dept. of Agriculture

4.0048, INTERACTION BETWEEN MICROORGANISMS AND PESTICIDES

B.T. JOHNSON, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Accumulation, retention and passage of polychlorinated pesticides in a freshwater food-chain are studied. Under controlled laboratory conditions experiments are performed with bacteria, algae, protozoa, crustacea, insects and fish using both labeled and non-labeled chlordane, toxaphene and methoxychlor alone and in combination with the non- pesticidal polychlorinated Aroclor series of compounds. Both simple and complex food-chains are developed. Only environmental levels of the pesticides are used. Residue analysis at various trophic levels are made using several chromatography methods, liquid scintillation, autoradiography and mass spectroscopy. Evidence of biological magnification in the concentration of pesticides is explored.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0049, DEVELOPMENT OF FIELD METHODS IN SAMPLING WATER FOR PESTICIDE ANALYSIS

D.L. STALLING, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

The use of plastic films, gel permeation materials (LH-20), and immobilized liquid phases to separate and concentrate low levels of pesticides from water will be studied. Polyethylene films and solvent filled plastic bags have demonstrated an ability to concentrate organochlorine pesticides from dilute water solutions. Various types of plastics will be evaluated. Concentration ratios, equilibration times, and uptake rates will be compared. Concentration of pesticides by partition using water flow through immobilized liquid phases and organic gel permeation resins show promise as simple sampling methods. Extraction with solvents denser than water will also simplify separation of pesticide from water.

Definition of the selectivity and general applicability of each approach will be important factors in selecting techniques for field use.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0050, EQUIPMENT AND PROCEDURES FOR CONTROL OF WEEDS AND BRUSH

C.L. DAY, Univ. of Missouri, Agricultural Experiment Sta., *Columbia, Missouri* 65201 (MO00153)

OBJECTIVE: Develop systems and equipment for control of weeds in field crops; equipment for control of weeds and brush on agricultural lands, rights-of-ways and commercial areas; develop more accurate and efficient methods of applying chemical herbicides.

APPROACH: Studies on various combinations of chemical and mechanical methods for controlling weeds in soybeans and corn are planned. A comparison will be made of pre-emergence applications of granular and liquid 2,4-D for weed control in corn. The effect of rainfall (or irrigation) on granular and liquid 2,4-D treatments will be made.

PROGRESS: Evaluation of equipment for incorporating herbicides with the soil was continued. Incorporation with some types of equipment resulted in yield reductions. Soil samples were analyzed with a gas chromatograph. Field studies to evaluate low volume spraying devices were used to supplement studies in the laboratory. A spinning disk type nozzle was found to be effective in reducing drift when compared with conventional and air atomizing nozzles. Field studies on directed spraying in corn were continued.

SUPPORTED BY U.S. Dept. of Agriculture

4.0051, CYTOGENETIC EFFECTS OF HYDROGEN FLUORIDE ON CORN

A.H. MOHAMED, Univ. of Missouri, Graduate School, *Kansas City, Missouri* 64110

Corn kernels of the genotype A sub 1 A sub 2 C super 1 RBWx will be germinated in the greenhouse in polyethylene pots containing a horticulture soil mixture. The seedlings will be fumigated with a concentration of HF too low to induce visible injury. After each period of treatment, the treated plants and their controls will be transplanted in the field. Microsporocyte samples will be collected from these plants at the right stage of development to study the effect of hydrogen fluoride on the meiotic chromosomes. Pollen grains will be collected from these plants and used to pollinate appropriate recessive female parents planted in the field. If hydrogen fluoride is able to induce any gene mutations or chromosomal aberrations, then the selected gene markers will help in identifying some of those events. The F sub 1 plants will be selfed and backcrossed to the appropriate recessive parents for linkage studies to determine the effect of HF on crossing over frequency.

4.0052, THE OROVADA, NEVADA BASIN ENVIRONMENTAL STUDY

B.R. PAYNE, Univ. of Nevada, School of Agriculture, *Reno, Nevada* 89507

The farming area surrounding the community of Orovada, Humboldt County, Nevada, grows alfalfa and grain for forage and seed, therefore, having occasion to use both chlorinated hydrocarbons and organophosphates for insect control. As defoliation is also practiced in readying the fields for seed harvest, some herbicides are used in the area. This region is a relatively new agricultural area and hence a very accurate account of the total amount of pesticides that have been used thus far could be ascertained.

The physical attributes of this valley for a study of pesticide use is ideal in many respects. The valley is isolated as are the ranches located in this region. The air is clear and uncontaminated from smog or other complicating factors. Due to its isolation, the area would permit good control studies associated with air application of insecticides, particularly in view of the fact that the ranches are also well separated. Irrigation water is obtained from deep wells. Little if any waste water reaches the Quinn River, and intermittent stream flowing through this valley. Therefore, most of the pesticide drift will occur during application or air and dust movement following treatments. The water usage in the valley, along with other attributes already mentioned, thus affords an excellent opportunity to closely estimate the total area of environmental contamination and the final deposition of all pesticides applied.

The proposed study would involve the recording of the total annual pesticide input in this rather compact agricultural area and the environmental drift patterns at predetermined seasonal times and sites. In addition to monitoring the atmosphere, soil samples would be analyzed for deposition of residues from atmospheric movement of soil particles.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.0053, THE ECOLOGY OF SELECTED SUBMERSED AQUATIC WEEDS

D. RIEMER, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00149)

OBJECTIVE: Study the growth and development of Myriophyllum, Potamogeton, and Elodea in axenic or algae - free cultures as affected by: Chemical variables, physical variables and biological variables and relate the results obtained to the distribution, management and control of the above mentioned genera.

APPROACH: Plants will be grown in plastic lined stock watering tanks with either filamentous algae or planktonic algae

or in tanks kept free. Growth will be measured and observations made on root development, tuber development, flowering, etc. Laboratory test will be conducted on plants grown in various nutrient solutions to determine the effects of varying levels of N, P and K and under different photoperiods to determine the effect of day length on vegetative growth and flowering. Germinating seeds of Potamogeton and Myriophyllum, at different temperatures in germination chambers.

PROGRESS: To determine effects of photoperiod on aquatic plants had no definite conclusions because of algae in the experimental vessels. Copper sulfate has been used to control algae in aquatic experiments but effects of the copper on the rooted plants are not known. Experiments were conducted to determine effects of a range of CuSO(4) 5H(2)0 levels in sago pondweed and Eurasian watermilfoil. Sago pondweed plants were grown in nutrient solution from tubers planted in washed sand. CuSO(4) 5H(2)0 was added at 0, 0.5, 10.0, 50.0 and 100.0 ppm. Browning of leaf tips was observed on all plants with 10 ppm and above at 24 hours. Stunting of plants was evident at 50 and 100 ppm after 5 days and there was no increase in height of plants after 8 days. Plants with 0.5 and 10.0 ppm CuSO(4).5H(2)0 were shorter than controls after 6 days. Root development was inhibited in all plants treated with 10.0 or more ppm. Dry-weight yields were lower in all copper sulfate treatments than they were in the controls. Result with Eurasian watermilfoil were similar although this species did not grow well in the nutrient solution used.

SUPPORTED BY U.S. Dept. of Agriculture

4.0054, GROSS EFFECTS OF HEXADECANOL AND PLASTIC SHEET BOTTOMS ON AQUATIC LIFE IN PONDS
D.B. JESTER, New Mexico State University, Agricultural Experiment Sta., *Las Cruces, New Mexico* 88070 (NM00414)

OBJECTIVE: Determine effects of hexadecanol monomolecular layer on aquatic life in ponds. Determine effects of plastic sheet bottoms on aquatic life in ponds. Determine effects of a combination of hexadecanol monolayers and plastic sheet bottoms on aquatic life in ponds.

APPROACH: Apply hexadecanol to the surface of two ponds, place polyethylene plastic bottoms in two ponds, apply both treatments to two ponds, and use two untreated ponds as controls. Gross effects of these treatments on aquatic life will be determined by use of standard limnological procedures to evaluate changes in physical and chemical factors, plankton quantity and quality, nekton volume and composition, benthos and crawfish populations, insect emergence, and fish survival and production.

SUPPORTED BY New Mexico State Government

4.0055, AERIAL CONTROL OF TREE FRUIT DISEASES
M. SZKOLNIK, New York State Agric. Sta., *Geneva, New York* 14456 (NYG00699)

OBJECTIVE: Adapt aircraft to the control of pome and stone fruit diseases. Investigate aerial equipment for application of dusts, spray concentrates, and ultra low volume. Determine phytotoxicity and compatibility of pesticides. Develop aerial spray programs. Study fungicidal residues and uniformity of coverage. Physical properties and drift of pesticides.

APPROACH: Fungicides will be developed as spray concentrates applied by fixed wing planes and helicopters for disease control without phytotoxicity. Different application equipment including that for ultra low volume (ULV) will be evaluated. Physical properties of sprays will be related to control and to persistence, degradation, and drift of pesticides.

PROGRESS: Aerial spray concentrates of fungicides were applied to mature apple trees by Grummen AgCat plane and Bell G-2 Helicopter, over each row, for the control of apple scab. Applications were made at 70X spray concentrates at 5 gallons per acre on 11 dates between April 20 (green tip) and July 2 (5th cover). The spring weather of 1969 was very favorable for development of the apple scab disease. Captan 80W, Manzate D 80W, and Dikar gave excellent control of scab on both leaves and fruit. The control Cyprex 65W applied by plane, helicopter, or by ground sprayer (at 2X with Speed Sprayer), was poor. This is in sharp contrast to excellent control with this dodine fungicide in many earlier years. Poor control was attributed to the development of tolerance or resistance of the scab fungus to dodine. Loss of this fungicide to the fruit grower would mean a serious setback. A single application of a 'massive rate' (about a sixfold increase per acre) of the fungicide Difolatan 4 flowable by airplane (Grummen AgCat) or by ground air blast sprayer replaced about 6 regular orchard sprays for the control of apple scab. Application was made at the half inch green stage of apple fruit bud development (April 27) and no fungicide was applied until the first cover spray (June 17) when a regular Cyprex spray program was resumed. Scab control in the single 'massive rate' application block was as satisfactory as it was in the block receiving a full spring fungicide spray program at regular intervals.

SUPPORTED BY New York State Government - Albany

4.0056, AGRICULTURAL CONTRIBUTIONS TO NUTRIENTS IN WATER
P.J. ZWERMAN, State University of New York, School of Agriculture, *Ithaca, New York* 14850

The objective of the project is to develop working approximations of parameters necessary for estimating the contributions of nitrogen and phosphorus from agricultural land to water for two specific purposes: (a) to permit estimation of the contributions from land under selected major land use systems, and (b) to permit identification of farming practices by means of which such contributions may be minimized.

To these ends, the immediate objectives would be to determine the effects of time, rate, and placement of fertilizers along with selected cultural practices, on the forms and amounts of nitrogen and phosphorus contributed to water under conditions of soil and climate representative of very extensive areas of the humid temperate region. In addition pilot analytical studies will be conducted to determine whether or not the major problems of determining organo phosphate and carbonate pesticides in the water samples can be solved adequately to justify the additional cost of monitoring them in the same experiment.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

4.0057, AN EVALUATION OF THE INSECTICIDE 'SEVIN' AS A WATERSHED POLLUTANT
J. BREZNER, State University of New York, School of Forestry, *Syracuse, New York* 12224 (WO1602)

OBJECTIVE: Provide information upon which to judge the potential of 'Sevin' as an environmental pollutant in forested areas.

APPROACH: A study area established on the Shackham Brook Watershed in central New York encompasses a 'treatment' and 'control' subwatershed. The treatment area will receive an aerial application of Sevin; then samples of soil, water, and aquatic insects will be taken at frequent intervals to be tested for the presence and concentration of Sevin residues.

PROGRESS: During the first two years of the study, preliminary surveys were completed and were followed by spraying operations. Techniques were devised and determined to be adequate. Tests of water and soil samples showed no residues of Sevin. Insect populations were negligibly affected.

SUPPORTED BY U.S. Dept. of Agriculture

4.0058, THE RECOVERY AND CHARACTERIZATION OF AGRICULTURAL CHEMICALS FROM SPENT PULP CHLORINATION LIQUORS
C.W. DENCE, State University of New York, School of Forestry, *Syracuse, New York* 12224 (FS-WO-3404)

OBJECTIVE: Develop methods of isolating and characterizing components of pulp chlorination effluent residues, assess potential as source of chemicals, and reduce pollution.

APPROACH: Prepare spent liquors approximating industrial pulp chlorination effluents. Separate the chlorolignins into its component parts and characterize the fractions. Test these fractions for use as insecticides, germicides, algicides and other chemical applications. Alter chlorolignins to improve their usefulness. Apply findings to reduce pollution. Apply findings to other wood wastes.

PROGRESS: The dissolved solids in a commercial spent chlorination liquor now have been isolated and partially characterized. The same materials were tested for insecticidal and fungicidal activity. The dissolved solids in chlorination liquors contain very little aromatic residue. Phenolic content is estimated at 5 to 10 percent of the solids. The various fractions of the chlorination solids were applied to milkweed bug and houseflies and showed no insecticidal activity. Likewise, the chlorination solids exhibited no fungicidal activity toward Penicillum Expansum, Lenzites Trabea, and Dutch Elm disease. The lack of insecticidal or fungicidal activity is attributed to the low phenolic content.

SUPPORTED BY U.S. Dept. of Agriculture

4.0059, PREVENTION OF PESTICIDE POLLUTION FROM COASTAL INSECT CONTROL PROGRAMS

R.C. AXTELL, Univ. of North Carolina, School of Agriculture, *Raleigh, North Carolina* 27607

This project will investigate the threat to estuarine animal life of pesticide residues drained from the state's farm lands by the rivers and streams.

The proposed project will have three main phases: (1) to determine present levels and distribution of pesticides in representative sites in sounds and estuaries along the coast and in streams and lakes of the Coastal Plain; (2) to study experimentally the breakdown or chemical alteration of pesticides in natural waters: and (3) to study the transfer and accumulation of pesticides in food chain organisms, particularly the common and economically important estuarine species.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

4.0060, NITROGEN, PHOSPHORUS, HERBICIDE MOVEMENT BY SOIL WATER AND SOURCES OF CONTAMINATION

J.F. LUTZ, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC03261)

OBJECTIVE: Determine direct contribution of fertilizers to nitrogen and phosphorus contamination of surface and subsurface runoff water from soils as affected by form, time and rate of fertilizer application, crop to which applied, soil properties, and meteorological and hydrological conditions. Lateral and vertical movement of several herbicides in soils and herbicide loss in surface and subsurface runoff from soils of different physical, chemical, and mineralogical properties.

APPROACH: Properly equipped, sealed watersheds will be treated with recommended rates of N, P, and selected herbicides and the amount of N, P, and herbicide in the runoff (surface and subsurface) over the flume determined. Losses of N and P in drainage water from other areas will be determined by analyzing water from tile outlets.

PROGRESS: Watersheds 1 and 2 of the Western North Carolina Cooperative Watershed Project at Waynesville were divided into four equal parts. Each of three segments was sprayed with 2,4-D, 2,4,5-T and picloram. A fourth segment was unsprayed. Two lbs/acre were used except on Watershed 4 in 1969 when 4 lbs were applied. When applied at 2 lbs/acre, the flume water contained 3 to 5 ppb 2,4-D but picloram and 2,4,5-T were not detected. When applied at 4 lbs/acre, as much as 48 ppb of 2,4,5-T was found, but 2,4-D and picloram concentrations never exceeded 3 ppb. Concentration in the surface runoff water was considerably greater because of a very heavy rain immediately following application. However, total loss amounted to only .04, .01, and .01% of the applied 2,4-D, 2,4,5-T, and picloram, respectively. Watershed 2 was fertilized with 200 lbs of N and 100 lbs of P(2)O(5) in 1968 and with 100 lbs of N and 100 lbs of P(2)O(5) in 1969. Watershed 1 was unfertilized. Of the total fertilizer applied in both years, less than 11% of the nitrogen and less than 2% of the phosphorus was lost in runoff water. Most of the nitrogen loss was caused by an exceedingly heavy storm immediately following the application of the fertilizer in 1968. 1969 losses were minimal. Only negligible quantities have been lost from the unfertilized watershed.

SUPPORTED BY U.S. Dept. of Agriculture

4.0061, CONTAMINATION OF SURFACE AND GROUND WATER WITH INSECTICIDES AND HERBICIDES APPLIED TO CULTIVATED CROPS

T.J. SHEETS, Univ. of North Carolina, School of Agriculture, *Raleigh, North Carolina* 27607

The movement of DDT, toxaphene, trifluralin, and fluometuron in surface water arising from natural rainfall in cotton fields will be studied. Cotton will be grown and sprayed with the four pesticides at dosages and frequencies employed by farmers for pest control. Surface water from small plots within large (3 to 5 acre) experimental fields will be collected after each rain during the growing season and analyzed for the pesticides.

Seasonal changes of pesticide residues in a farm pond located within one of the experimental areas will be followed by analyzing water and sediment after each rain.

The persistence of the four pesticides and their movement downward will be studied in two soils (the two experimental sites). Possible contamination of ground water will be investigated by analyzing water from wells located within cotton fields that are sprayed with the four pesticides during each of three years.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

4.0062, FATE OF POLLUTANTS IN GROUND WATER

M.R. SCALF, U.S. Dept. of the Interior, Federal Water Quality Admin., *Ada, Oklahoma* 74820

Traditionally, it has been and continues to be the practice of water users in the High Plains area of West Texas and Eastern New Mexico to recharge aguifers with playa lake water. In doing so, the aquifer recharged risks contamination by chlorinated hydrocarbons and nitrates resulting from agricultural practices. It is of concern that chlorinated hydrocarbons, in particular, adsorb to aquifer material in the near proximity of the recharge well and then are released in high concentrations when that well is pumped. This project is being conducted cooperatively by the Robert S. Kerr Water Research Center of the Federal Water Pollution Control Administration and the Southwestern Great Plains Research Center of the U.S. Department of Agriculture. The experiment will be at the latter's installation at Bushland, Texas.

The scope of this project will be to determine the distance which pollutants travel in a fresh water aquifer under recharge conditions and the temporal distribution of these concentrations when that same well is pumped.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

4.0063, DRIFT CONTROL OF PESTICIDES

L.O. ROTH, Okla. St. Univ., Agricultural Experiment Sta., *Stillwater, Oklahoma* 74075 (OKL01264)

OBJECTIVE: Measure and evaluate drift potential of liquid pesticides drops as this drift potential is affected by atomizing devices and physical characteristics of liquid; build, test and evaluate prototype liquid pesticide applicators which have a low drift potential.

APPROACH: Photographic assessment equipment and methods will be used to measure drop sizes generated by three general atomizing devices- -laminar flow orifices, mechanical choppers and pulsed wave generators. Physical properties of different liquid pesticides will also be studied to determine effect of viscosity, surface tensions and particulating agencies on drift potential of generated drops. Prototype liquid pesticide applicators will be built, tested and evaluated. Field studies under varied conditions will be made to determine degree of drift control achieved.

PROGRESS: Major effort has been devoted to evaluation of a method of introducing wettable powders into a spray system downstream of the pump. The output of the system as a function of rotor speed was nonlinear over the range of 0.1 to 1.2 lbs/min. Magnetostriction as a means of drop size control continued as an important research activity. Apparently rod-orifice plate clearance is not as critical as first observed. Control of drop formation using magnetostrictive devices is possible in such ordinary

atomizers as cone or fan nozzles. Satellite drops seem to appear under some regions. This phenomenon must be further investigated. Air stripping of small drops with a counterflow air stream was effective at air velocities above 10-12 fps. Field equipment was developed for using electrostatic stripping and dispersion and this equipment was used in field application of 3 sized drops--100, 200 and 300 micron diameter.

SUPPORTED BY U.S. Dept. of Agriculture

4.0064, PHARMACOLOGICAL AND ECOLOGICAL EFFECTS OF PESTICIDES

C.E. WARREN, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00693)

OBJECTIVE: Developing standards for the use of toxic substances that are adequate to protect the productivity of fresh waters for organisms of value to man. Obtain understanding of how toxic substances influence the various biological functions of the individual organism; and obtain understanding of how toxic substances influence food relations in biological communities.

APPROACH: Pharmacological and bioenergetic approaches will be used in studies of the influences of toxic substances on the biological functions of aquatic organisms; food chains in simplified biological communities will be studied to determine the influence of toxic substances on food relations.

PROGRESS: Recently initiated studies have to do with the influence of pesticides on the population dynamics of fish in ecological systems that provide the fish-food resources. Working with Lyle Clavin of our Statistics Department we hope to develop models of population growth that contain environmental variables including pesticides. Preliminary experiments have demonstrated the population densities of fish which may develop when space is limited, but food is not. Other preliminary experiments have been conducted that show the extent of toxicity from dieldrin imparted to the fish from water, from food and from the two sources combined. This information has provided us with a basis for selecting experimental dieldrin concentrations in the population studies, and the sizes of aquaria to be used. Our previously reported toxicological investigations have included studies at the enzyme, whole animal, and simplified ecological levels. To provide information at the cellular levels the effects of the important industrial toxicant pentachlorophenol on tissue cultures of embryonic cells from Oncorhynchus kisutch have been studied in media containing agamma calf serum. Threshold effects are obtained with 40 mg/l of pentachlorophenol. With 80 mg/l the number of cells is reduced as is the nitrogen, fat, and dried weight of cells developing. However, the individual cells have a larger volume, and contain more nitrogen and have a higher dried weight than control cells.

SUPPORTED BY U.S. Dept. of Agriculture

4.0065, TRANSFER OF PESTICIDES THROUGH WATER, SEDIMENTS, AND AQUATIC LIFE

C.E. OLNEY, Univ. of Rhode Island, School of Agriculture, *Kingston, Rhode Island* 02881

There is virtually no information on the extent of environmental contamination by pesticides in the state of Rhode Island and this project is aimed at filling this gap in our knowledge.

Samples of water, sediment, and aquatic life from selected streams and ponds in the state will be collected at regular intervals and analyzed for chlorinated hydrocarbon and organic phosphate pesticides. Watersheds, both rural and urban, where pesticides have been used as well as those where chances of direct contamination are remote will be sampled.

Should biologically significant residues be found, an attempt will be made to trace the source of the pesticide.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch

4.0066, FISHERIES UNIT

R.L. APPLEGATE, South Dakota State University, Agricultural Experiment Sta., *Brookings, South Dakota* 57006 (SD00914)

OBJECTIVE: Research various problems of fish and aquatic habitats in South Dakota.

APPROACH: Partial contribution by University to M/U between U and Cooperative Fishery Unit between U. S. Sport Fisheries and Wildlife and S. D. Department of Game, Fish, & Parks. Work program varies according to the annual agreement of the coordinating committee.

PROGRESS: This project is part of the University's contribution to the Cooperative Fishery Unit as per memorandum of agreement. Projects included: fish population of Lake Poinsett as indicated by the catch of four types of gear; food selectivity of bigmouth buffalo in Lake Poinsett; survey of chemical biocide levels in Lake Poinsett; population dynamics of Daphnia pulex in Lake Poinsett.

SUPPORTED BY South Dakota State Government

4.0067, CHEMICAL BIOCIDES IN LAKES

Y.A. GREICHUS, South Dakota State University, Agricultural Experiment Sta., *Brookings, South Dakota* 57006 (SD00471)

OBJECTIVE: Determine the levels of chemical biocides in the ecosystem of a prairie lake (Lake Poinsett). Study the effects of these chemicals on the ecosystem of this lake.

APPROACH: Plant and animal species of the food chain of the lake fish will be collected at the inlet and outlet areas, the littoral zone, the transition zone and the settling basin zone. The species will be identified and analyzed for pesticides. The fish, also, will be analyzed for pesticides.

PROGRESS: All samples collected for this study have been analyzed and the data are now being processed. Several samples (of both sexes in most cases) of 12 species of fish were examined for 11 insecticides on both a tissue and fat basis. In addition, the water and some components of the food chain have been examined. Some work on fish-eating birds has also been undertaken.

SUPPORTED BY South Dakota State Government

4.0068, IMPROVED DISTRIBUTION AND PLACEMENT OF CONCENTRATE PESTICIDE MATERIALS

J.A. MULLINS, Univ. of Tennessee, School of Agriculture, *Knoxville, Tennessee* 37916

The Research: A concentrated team effort in research is needed to develop these promising application techniques for pest control. Engineers would develop field test equipment for specific placement of chemicals on plant parts and biological scientists would make bio-assay studies. Comprehensive evaluations would be made as to the importance of rate, distribution placement, timeliness and physical properties of a chemical on biological control. Considerable emphasis should be placed on determining drift to adjacent rows, fields and into the atmosphere.

SUPPORTED BY Cotton Incorporated - Raleigh, N.C.

4.0069, CONTROL OF FIELD BINDWEED, BLUEWEED, ETC.

A.F. WIESE, Southwestern Great Plains Ctr., *Bushland, Texas* 79012 (TEX00686)

OBJECTIVE: Develop and improve chemical and cultural practices for efficient and economical control of sub-humid perennial broadleaf weeds under a wide range of climatic and cropping conditions.

APPROACH: Determine the effect of root and foliage carbohydrate level in blueweed, bur ragweed and alkali mallow on 2,4-D toxicity; factors affecting toxicity and breakdown of TBA, PBA and fenac; the feasibility of the combined use of tillage and soil sterilants for bindweed control; and study spray drift and evaluate new herbicides.

PROGRESS: Good control of silverleaf nightshade from June to August was obtained with 2,4-D, MCP, each at 1 lb/A, picloram at 1/2 lb/A, picloram 2,4-D at 1/2 1 lb/A, and VCS 438 at 2 lb/A. Diuron and MSMA at 1 and 3 lb/A gave good control. The 6- and 9-in. stage of the weed was more susceptible to herbicides than the 3-in. or bud stage. MSMA has proven good for control of woollyleaf bursage. Woollyleaf bursage and blueweed roots were traced to 21 and 14 ft. deep. Silverleaf

nightshade roots were observed to 7-1/2 ft., but terminated at 3 ft. Bindweed roots were observed in the bottom of 8 foot holes. Woollyleaf bursage roots weighed 1800 lb/A. Blueweed roots weighed 2600 and 1380 lb/A from non-cultivated and cultivated fields. Bindweed produced about 1200 lb/A on both cultivated and non-cultivated fields. All weeds except woollyleaf bursage had about 50% of their roots in top 2 ft. of soil. Woollyleaf bursage roots were evenly distributed through the top 4 ft. of the soil profile. Bindweed roots contained 460, 270, and 120 lb/A starches, sugars, and protein. Blueweed and woollyleaf bursage had smaller amounts of stored foods. Perennial weed studies cover over 1.5 million acres.

SUPPORTED BY U.S. Dept. of Agriculture

4.0070, EFFECTIVENESS OF WATER-IN-OIL EMULSION SPRAYS FROM THE BIFLUID SYSTEM FOR WOODY PLANTS

R.H. HAAS, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (TEX01509)

OBJECTIVE: Determine the effectiveness of water-in-oil emulsion sprays from the bifluid system in controlling woody plants on rangelands and industrial rights-of-way; determine the size and distribution of droplets deposited by the bifluid system from helicopter and fixed-wing aircraft; the influence of various emulsifiers and oil:water ratios on the characteristics of water-in-oil emulsion sprays deposited from the bifluid system and their relative effectiveness for woody plant control; and the influence of emulsifiers and oil:water ratios used with the bifluid system on the absorption and translocation of herbicides by woody plants.

APPROACH: Field and laboratory studies will be established to determine the effectiveness of invert emulsions for the control of mesquite, post oak, and mixed hardwood species. Appropriate tests will be made to determine the size and distribution of droplets deposited by the bifluid system and the influence of droplet size on spray effectiveness.

PROGRESS: Data were summarized from studies with hydroxyethyl cellulose, used as a spray thickening agent. These studies show the presence of an appreciable number of large droplets in the thickened spray deposit. Spray deposit patterns with thickened sprays are more variable and droplet counts per unit area are less than those obtained with conventional sprays. Nozzle arrangements used for conventional sprays are usually not adequate for good distribution of thickened sprays with maximum drift control properties. Research from this project shows that substantial drift control can be obtained through the application of thickened spray solutions. A general characteristic of all thickened sprays is the production of a broad spectrum of droplet sizes. The very small, most driftable droplets are not eliminated from fixed-wing spray deposits, but may be substantially reduced under proper application conditions. The successful use of thickened sprays depends upon the use of correct concentrations of the thickening agents, proper nozzle design, placement and orientation. Applied under less than optimum conditions, any one of the thickened solutions can produce sprays containing considerable drift susceptible droplets.

4.0071, INVESTIGATION OF PESTICIDE DRIFT IN THE LOWER RIO GRANDE VALLEY OF TEXAS

H.A. DEAN, Lower Rio Gr. Res. & Ext. Ctr., *Weslaco, Texas* 78596 (TEX01521)

OBJECTIVE: Introduce, mass-rear and distribute beneficial insects and predaceous mites. Determine toxicity of various agricultural chemicals to beneficial and injurious insects of citrus. Evaluate beneficial insect. Investigate methods of selective chemical control. Determine pesticide levels in the atmosphere.

APPROACH: The quantity of drift will be measured under variable climatic conditions. Pests will be studied as to means of lessening their relative importance, but brown soft scale will be given priority in initial investigations.

PROGRESS: Project held open for write-up of publication on pesticide drift with Mr. W. G. Hart of Entomology Research Division as senior author. Related work on brown soft scales is being done on State Project 848.

SUPPORTED BY Texas State Government - Austin

4.0072, PESTICIDES AND MICROBIAL ECOLOGY OF LAKE CHAMPLAIN

D.B. JOHNSTONE, Univ. of Vermont, Agricultural Experiment Sta., *Burlington, Vermont* 05401 (VT00155)

Objective: Obtain an ecological evaluation of the various types of microorganisms present in the waters of Lake Champlain. Determine the influence on microorganisms of pesticides in an aquatic environment. Determine the influence of pesticides on the number and distribution of microorganisms in an aquatic environment.

Approach: The aquatic microbial ecology in areas adjacent to the shoreline and relatively free of agricultural chemicals will be examined by standard microbiological precedures for culturing and enumerating microorganisms. This will be correlated with basic limnological data such as dissolved oxygen, temperature, etc. obtained by other investigators. Special emphasis will be placed upon those groups of bacteria that are active in organic matter decomposition such as nitrogen transformations.

Progress: Macro-environmental studies were conducted in the southern portion of Lake Champlain from Whitehall to Burlington. Bacterial populations were correlated with various limnological parameters. This data may become useful in evaluating the pollution by the paper mills as well as thermal pollution by a proposed nuclear power generating station in this area. A new device was designed and built to collect water samples aseptically at various depths. The taxonomy of certain bacteria is being studied by polyacrylamide gel electrophoresis of proteins. An investigation of the nutritional characteristics of representative yeast isolates from Lake Champlain was completed.

4.0073, DISTRIBUTION OF ORGANOPHOSPHORUS PESTICIDE RESIDUES IN NATURAL WATERS AND SEDIMENTS

M.L. YATES, U.S. Dept. of the Interior, Geological Survey, *Arlington, Virginia* 22209

The effect of extensive use of organophosphorus pesticides on the water quality in many areas of southern Florida needs to be evaluated. Over 268,000 lbs of organophosphates were employed from July 1966 to July 1967 in Dade County alone. National Pesticide Monitoring Program includes a need to evaluate residue levels of many organophosphates in water systems, but little data has so far been produced. If a serious residue problem exists then programs to reduce or eliminate the use of certain materials may be required.

Compounds to be studied, based on amount of use in given areas, include malathion, parathion, guthion, dimethoate, delnay, ethion, tedion, and trithion. Data on the amount and types of organophosphorus residues in water, sediments and probably plant life will be obtained. Degradation and resistance studies on specific compounds will be run. Parameters such as pH, Eh, D.O. and temperature of the water environment will be included. The results will aid in evaluation of the source, transport and ultimate fate of these compounds in the hydrologic cycle. The pesticide analyses will be carried out in the laboratory using techniques of extraction, cleanup and instrumental analysis developed in conjunction with other Survey labs.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

4.0074, HERBICIDE RESIDUES IN IRRIGATION WATER AND IN CROPS AND SOILS IRRIGATED WITH TREATED WATER

F.L. TIMMONS, Battelle Memorial Institute, *Richland, Washington* 99352 (0750-09-09(C))

OBJECTIVE: Determine the presence and concentrations of selected herbicides and degradation compounds or metabolites in crops and soils irrigated with water containing known concentrations of each herbicide.

APPROACH: Acrolein and copper sulfate will each be applied to a typical irrigation canal at a known concentration and determinations of concentrations remaining in the water, suspended material, and bottom soil will be made at various

distances and time intervals after application. Acrolein, 2,4-D, silvex and two other herbicides will each be applied in three different concentrations to irrigation water which will be applied by overhead and furrow irrigation methods to corn, soybeans, and sugarbeets grown in field plots. Samples of treated water and irrigated soil will be taken at the time and one week after the irrigation. Samples of edible portions of the crops will be taken at maturity. All samples will be analyzed by appropriate methods to determine the presence and concentrations of the herbicide and of important degradation compounds or metabolites.

PROGRESS: Acrolein applied at 0.7 ppm during a period of 6 hours 20 minutes in an irrigation canal. The volume of water flow was 135 cfs and the water temperature was 48 F. Water samples taken at nine locations downstream, 1, 3, 6, 9.5, 12.5, 16, 19, 22.5, and 27 miles below the point of application during 30 hours after treatment, showed a progressive reduction in concentration of copper ion in the water from 0.710 ppm at Mile 1 to 0.269 ppm at Mile 27. The concentration was reduced more rapidly during the first 9.5 miles than during the subsequent 17.5 miles. The total dissipation of applied copper was 44.1% after 9.5 mi. and 62.6% after 27 mi. All fish in live boxes below the acrolein application were killed even at the station 27 mi. below. Volatility of acrolein according to measurements with volatilimeters showed that volatilization accounted for only a small proportion of the reduction in concentration at the unusually low temperature. In an earlier experiment conducted in a similar canal in August 1966 when the water temperature was 63-64 F losses by volatilization were 50% in the first 3 mi. and 90% in the first 10 mi. that treated water flowed down the canal.

4.0075, TERMINAL RESIDUES OF CHLORINATED HYDROCARBON PESTICIDES IN LAKE MICHIGAN AND ASSOCIATED TRIBUTARIES

G.M. BOUSH, Univ. of Wisconsin, School of Agriculture, *Madison, Wisconsin*

The objectives of this project are to determine the metabolic fates of persistent chlorinated hydrocarbon insecticides, particularly DDT and dieldrin, in microorganisms isolated from the waters of Lake Michigan and associated tributaries. The study is designed to measure the biological effects of such microbial conversion of pesticides in selected aquatic environments.

The experimental approach first consists of isolating microorganisms from various locations, and then incubating the candidate radio-labeled 14C insecticides with pure cultures of the microbial isolates. When the general tendencies of the metabolic capabilities of the microorganisms have been established, efforts will then be made to study the presence of such metabolites under natural aquatic situations.

To date, a number of microorganisms have been isolated from water and lake bottom silt from Lake Michigan and related water systems. The majority of isolates convert DDT, under laboratory conditions, to DDD (TDE). Only four isolates produced DDE from DDT. Several cultures which further metabolic activities were observed from isolates obtained from the Fox River-Green Bay area.

SUPPORTED BY Wisconsin State Government - Madison

4.0076, CHLORINATED ORGANIC CONTAMINANTS IN THE MILWAUKEE RIVER

G.F. LEE, Univ. of Wisconsin, School of Engineering, *Madison, Wisconsin*

The occurences of chlorinated organic contaminants in the Milwaukee River system and western Lake Michigan has been investigated. Mass spectrometric analyses have verified the presence of mixtures of chlorinated biphenyls, and semi-quantitative GLC analyses based on commercial mixtures as standards have described the relative concentrations of the chlorinated biphenyls in fish and water throughout the study area. However, the lack of suitable standards results in the inability to adequately correlate environmental data because of the many isomers which comprise the mixtures.

The proposed study is an investigation of the aqueous environmental chemistry of the chlorinated biphyenyls. The initial objective is the development of analytical conditions and standards which enable quantitative analyses of individual or groups of isomers to be made. Subsequently, the fate of the chemicals in the environment will be determined through evaluations of the relative significances of sorption on sediments and planktonic communities, and stabilities of the chlorinated biphenyls toward biological and chemical degradation.

B. SOIL ENVIRONMENT

4.0077, INTERACTIONS OF SOIL MICROORGANISMS AND HERBICIDES

E.A. CURL, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA-05-0004)

OBJECTIVE: Study effects of atrazine, cotoran, and trifluralin on growth behavior and interactions of specific soil microorganism. Determine the role of soil microorganisms in degradation of cotoran, trifluralin, and diquat.

APPROACH: Growth-related responses of phytopathogenic fungi (Sclerotium rolfsii, Rhizoctonia solani, Fusarium vasinfectum, and others) to herbicides will be determined with regard to mycelial growth, sporulation, sclerotium production, spore and sclerotium germination, adaptation and nutrient uptake. Also effects on populations and antibiotic production by pathogen-inhibiting organisms (such as Trichoderma viride) will be studied. The interrelations of herbicides and C/N balance as affecting microbial behavior will be given special attention. For degradation studies, microorganisms found by enrichment culture to predominate and persist in herbicide-treated soil will be studied individually for utilization and breakdown of herbicides. Pathways of degradation will be studied by isotope and manometric techniques.

PROGRESS: Effects of herbicides on plant pathogens were determined in soil culture, and microbial degradation of herbicides was studied. Growth (CO_2 evolution), oxalic acid formation, and sclerotium production by Sclerotium rolfsii were inhibited by 12 ppm active atrazine in soil, this effect being greatest in soil of high C:N ratio. Saccharase and polygalacutronase activity in the soil also decreased. Growth of Trichoderma viride (antagonistic saprophyte) was stimulated but spore production delayed; stimulation was enhanced in soil of low C:N ratio. Atrazine in soil at 20-80 ppm stimulated CO_2 production by Fusarium oxysporum f. vasinfectum and increased the ratio values of C evolved/NO_3-N consumed and C/glucose consumed. Prometryne at 20 ppm in soil stimulated respiratory activity, NO_3-N uptake, and chlamydospore production by F. vasinfectum, but germination of spores was directly inhibited by increasing prometryne; this inhibition pattern fluctuated according to kind of saprophytic organisms pre-grown in the soil. The research suggests a possible relation to plant disease and biological control. In degradation studies, five microorganisms degraded diquat in C-labeled medium.

SUPPORTED BY Alabama State Government

4.0078, HERBICIDE EFFECT ON SOIL MICROORGANISMS ESPECIALLY INTERACTIONS WITH PHYTOPATHOGENIC FUNGI

E.A. CURL, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA-05-0018)

OBJECTIVE: Determine concentrations of herbicides necessary to effect changes in soil microbial populations and production of fungitoxic metabolites. Determine effect of herbicides on the natural fungistatic and lytic properties of crop soils. Determine effect of selected herbicides on survival growth, and reproduction of specific phytopathogenic fungi.

APPROACH: Herbicides involved will include atrazine, trifluralin, paraquat, and EPTC. Primary phytopathogens for study will be Sclerotium rolfsii, Rhizoctonia solani, Fusarium vasinfectum and Pythium ultimum, with special tests provided for Helminthosporium spp. and Sclerotinia trifoliorum. Standard procedures will be used for testing herbicide effects on microbial populations. Direct methods of Lockwood will be employed for

fungistasis studies, and growth and survival will be studied by standard or modified manometric and enzymatic procedures.

PROGRESS: Effects of technical grade herbicides on soil fungi (primarily plant pathogens) were determined in vitro. Atrazine in nutrient solution culture, at levels of 10 ppm or more inhibited mycelial production of Rhizoctonia solani and Sclerotium rolfsii. Atrazine in sterilized soil substrate at 8 ppm caused increased CO(2) evolution by S. rolfsii. Higher levels were inhibitory. The antibiotic saprophyte, Trichoderma viride, was stimulated by atrazine. Paraquat in excess of 6.35 ppm inhibited growth of R. solani in liquid culture and S. rolfsii in soil. Trifluralin in liquid culture at 10- 100 ppm inhibited S. rolfsii but in soil at 6.25 ppm CO(2) production increased; higher levels in soil inhibited the fungus. EPTC in soil at levels above 5 ppm caused an increase in saccharase and phosphatase activity; lower levels had no effect. These effects on fungi were accompanied by similar effects on nutrient utilization and (for S. rolfsii) oxalic acid production. Trifluralin at low levels (0.6-10 ppm) enhanced chlamydospore production and germination by Fusarium oxysporum f. vasinfectum in soil. Whole microbial populations increased. EPTC, prometryne, and cotoran in soil cultures inhibited sclerotium production by S. rolfsii, while diuron and paraquat had least effect. During the course of these studies enzymatic methods were developed for assessing growth of single and mixed cultures.

SUPPORTED BY Alabama State Government

4.0079, INACTIVATION AND LOSS OF PESTICIDES FROM SOIL

A.E. HILTBOLD, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA00200)

OBJECTIVE: Determine inactivation and loss of pesticides from soil by volatilization, microbial degradation, non-microbiological degradation, movement of water through or over soil, for the purpose of identifying primary loss processes, relating these processes to soil properties, and predicting pesticide persistence.

APPROACH: Relative biological and non-biological breakdown of atrazine will be determined by measurement of hydrolysis of labeled atrazine in soil samples incubated with normal microflora and in autoclaved samples of these soils. Volatilization and microbial degradation of fluometuron and trifluralin will be determined in soil samples with C labeled herbicide during incubation in controlled air streams. Field experiments will provide bioassay data on persistence of preplant applications of atrazine, trifluralin and nitralin. Analysis of field plot soils and harvested crops will provide information on movement and uptake of arsenic from methanearsonates.

PROGRESS: Processes of retention and loss of benefin (N-butyl-N- ethyl-alpha,alpha,alpha-trifluoro-2,6-dinitro-p-toluidine) were investigated. Benefin was placed at precise depth in Orangeburg, Greenville and Dothan loamy sands in the field, then soil samples were obtained at intervals during the season. During the first 2 weeks the original 20 ppm of benefin decreased to 10 ppm while the untreated soil above and below acquired 1 ppm of benefin. Despite 19" of rainfall benefin was not found deeper than 1' below its position of placement. A monodealkylated degradation product appeared in deeper soil layers late in the season. Laboratory incubation of these soils containing (C)-labeled benefin showed slow biodegradation of benefin. Increasing microbial activity with added organic matter stimulated benefin degradation. Primary loss process of benefin was found to be volatilization to the atmosphere. Leaching played little or no part except to move degradation products downward. At normal use rates for weed control in peanuts, benefin did not persist into the fall and residues in the soil were nonphytotoxic.

SUPPORTED BY U.S. Dept. of Agriculture

4.0080, INFLUENCE OF SELECTED HERBICIDES ON THE NATURAL PROCESSES OF SOIL MICROORGANISMS

P.C. KEARNEY, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (0750-08-06(GR))

OBJECTIVE: Determine the effects of several herbicides on natural fungitoxic and fungistatic properties of crop soils and the effects of herbicides on survival, growth, reproduction, population density, and kinds of specific phytopathogenic soil fungi.

APPROACH: Herbicides will be applied at rates above and below recommended rates and major groups of microorganisms will be isolated and enumerated by standard dilution procedures. Effects of herbicides on the production of substances toxic to soil-borne plant pathogens will be studied in crude soil systems and in pure cultures. The quantitative and qualitative nature of fungitoxic substances produced by individual isolates as influenced by herbicides will be sought by attempting to identify chemicals responsible for fungistatic and lytic effects, to determine the ability of phytopathogenic soil fungi and pathogen- inhibiting microorganisms to utilize as carbon sources those herbicides that interact, and determine effects of herbicides on growth.

PROGRESS: Effect of the herbicide atrazine on growth of Fusarium oxysporum f. vasinfectum was studied in liquid and soil cultures containing 0, 8, 20, 40, and 80 ug of technical grade atrazine per milliliter of medium or per gram of soil. In liquid cultures of the fungus significantly lower mycelial production occurred at the two highest concentrations of herbicide 6 days after inoculation than in other treatments. This difference was accompanied by significantly higher amounts of residual glucose, nitrate-nitrogen, and inorganic phosphate in the medium (lower utilization). Conductivity values for the liquid-culture filtrate at 6 days were highest for the 40- and 80-ug treatments. No significant differences between treatments were evidenced for any variables at the last sampling date 10 days after inoculation. Atrazine significantly increased CO(2)-carbon production in soil cultures of the fungus at concentrations of 20, 40, and 80 ug/g. This stimulation was first evident 6 days after inoculation and remained so until the last sampling 14 days after inoculation. No significant differences in nitrate-nitrogen consumed were found between soil treatments, when analyzed at 14 days. The ratio of amount of carbon evolved to nitrate-nitrogen consumed was significantly highest for the 3 highest herbicide treatments.

4.0081, PESTICIDE MOBILITY AND DEGRADATION IN SOIL-WATER SYSTEMS

G.R. DUTT, Univ. of Arizona, Agricultural Experiment Sta., *Tucson, Arizona* 85721 (ARZT-2020-4151-018)

OBJECTIVE: Identify the physical-chemical properties of pesticide- soil-water systems. Develop a mathematical model which will provide semiquantitative predictions of pesticide movement in soil-water systems.

APPROACH: Carbon 14 labeled Picloram, 2,4-D, 2,4,5-T will be solubilized in aqueous solutions of different ionic composition and concentrations over a range of temperatures. Using data from other cooperation stations and the above, a system analysis model will be developed.

PROGRESS: A model for calculating the distribution and soil solution concentration of atrazine was altered to take into account the change in solubility of atrazine with solutions of electrolytes, the difference in sorption and desorption isotherms, and the change in distribution coefficient with different ratios of Na, Ca, and Mg. The data from leaching studies are being compared with theoretical results. These correlations seem to confirm that the above findings are responsible for the tailing off of breakthrough curves.

SUPPORTED BY U.S. Dept. of Agriculture

4.0082, REACTIONS OF TRIAZINE-HERBICIDES WITH SOIL COMPONENTS

G.R. DUTT, Univ. of Arizona, Agricultural Experiment Sta., *Tucson, Arizona* 85721 (ARZT-5901-155-844)

OBJECTIVE: Study the reactions of atrazine herbicide in calcareous soils.

APPROACH: By necessity, the approach was made to develop analytical methods for quantitative detection of atrazine in soil systems. The methods investigated included thin layer chromatography, gas liquid chromatography, colorimetry, U.V. spectroscopy and radioactive isotope techniques. The most satisfactory method involved the use of radioisotopes. Bonding mechanisms were investigated. Quantitative recovery of atrazine in aqueous soil extracts indicates a relative weak bonding. Atrazine bonding with organic matter constituents is real and important in the retention of the herbicide in soil.

4. PESTICIDES

PROGRESS: This project was supplemental to (ARIZ-9010-155-591, Accession 00001010) and was discontinued 30-06-68. The distribution coefficient was studied as a function of exchangeable ions (Ca, mg and Na). It was found that atrazine was not as strongly held by Na-soils as on Ca and Mg-soils. The solubility of atrazine was found to be a function of ionic strength. Solubility decreases as ionic strength increases. It was found that sorption isotherms are different than desorption isotherms. This seems to explain why there is a tailing off in breakthrough and elution curves.

SUPPORTED BY Arizona State Government

4.0083, RESIDUES OF SELECTED PESTICIDES - NATURE, DISTRIBUTION, PERSISTENCE IN PLANTS, ANIMALS & PHYSICAL ENVIRONMENTS

G.W. WARE, Univ. of Arizona, Agricultural Experiment Sta., *Tucson, Arizona* 85721 (ARZT-2020-4161-014)

OBJECTIVE: Metabolism of pesticide residues by animals and plants. Study metabolism and excretion of pesticide residues in mammals, certain invertebrates and in higher plants. Develop specific quantitative methods of analysis to measure metabolites in animal and plant tissues.

APPROACH: Expose test animals to pesticides by standard dosing techniques or through the feed and other routes when appropriate. Excretion and deposition of the pesticide will be followed by using chemical methods or radio-labeled compounds. Pesticide metabolism by animals and plants will be through a search for metabolites using chromatrographic, radiorespimetric, autoradiographic, and other approaches applied to subcellular preparations or the living organism.

PROGRESS: The metabolic pathways of endosulfan I and II, diol, lactone and alpha-hydroxy ether have been explored in sufficient detail in the rat to explain their general routes and breakdown products. Three routes of alfalfa exposure to C -DDT contaminated soil, (1) an emulsion injected around the roots, (2) seed germination and growth in treated soil, and (3) plants surrounded by a layer of treated soil, indicate that DDT translocation from soil to above-ground plant parts is not a route of forage contamination. The half-lives of DDT, DDD and endrin in irrigated soils are estimated to be 24, 20 and 16 months, respectively. Under desert or uncultivated conditions the half-lives are DDT 26 months, DDD 13 months and endrin 10 months.

SUPPORTED BY U.S. Dept. of Agriculture

4.0084, INACTIVATION AND LOSS OF PESTICIDES FROM SOIL

R.E. TALBERT, Univ. of Arkansas, Agricultural Experiment Sta., *Fayetteville, Arkansas* 72701 (ARK00633)

OBJECTIVE: Determine inactivation and loss of herbicides from soil by volatilization, retention and release, and movement of water through soil for the purpose of identifying primary loss processes, relating these processes to soil properties, and predicting herbicide persistence.

APPROACH: The physical-chemical aspects of selected herbicides with respect to their inactivation and loss from soils will be studied; Volatility under controlled laboratory conditions utilizing vapor trapping devices to trap samples for chemical and biological analysis, retention and release using adsorption isotherms and diffusion methods, and movement using soil column techniques.

PROGRESS: The behavior of nitralin and trifluralin in soils was studied. In a field study, the two compounds were similar in residual activity as indicated by bioassay. Approximately one-half of the activity had dissipated after 42 days and three-fourths had dissipated by 172 days. Surface application had dissipated by 42 days. Persistence was greater from 2- and 4-inch incorporation than from 1- inch incorporation. After 1 year, significant activity from both compounds was detected where 2 lb/A had been applied. Where plastic shelters were used to protect plots during periods of rainfall, surface applications of nitralin showed no significant loss in activity during a 22-day period. The use of soil amendments to inactivate trifluralin and nitralin was studied. Powdered activated carbon was approximately 100 times more effective than wheat straw, and wheat straw was approximately 10 times more effective than cotton stalks. In comparing various grades of activated carbons, 3- to 4-fold differences in their efficiency were noted, however, it was difficult to make associations of inactivation efficiency with any property of the carbon. With Darco GFP, 0.177 ppmw nitralin or 0.174 ppmw trifluralin were inactivated by each additional 100 ppmw of carbon added. In other studies, the use of dinoseb to inhibit the microbiological hydrolysis of ester derivatives of amiben was demonstrated.

4.0085, MOVEMENT OF CHLORINATED HYDROCARBON INSECTICIDES IN SOILS

J.P. MARTIN, Univ. of California, Agricultural Experiment Sta., *Berkeley, California* 94720 (SWC-024-BELT-12)

OBJECTIVE: Determine the method of movement of chlorinated hydrocarbon insecticides in soils and evaluate the influence of soil properties, temperature, humidity, and soil-water content on movement, particularly vapor-phase movement, and volatilization losses into the atmosphere.

APPROACH: Laboratory experiments will be conducted to evaluate the influence of various soil and environmental factors on movement and volatilization of chlorinated hydrocarbon insecticides. Commonly used insecticides such as DDT, lindane, dieldrin, aldrin, etc., will be added to soils typical of Southwestern semi-arid areas. Rate of movement from a treated to an untreated portion of the soil will be used to calculate diffusion coefficients and predict movement under various field conditions including losses to the atmosphere by volatilization which would occur after application of insecticides in the field.

PROGRESS: A theory was developed to describe the combined vapor and nonvapor' phase diffusion of a volatile insecticide in soils and compared with the diffusion of lindane in a Gile silt loam. At a 10% soil-water content, 50% of the lindane diffuses in the vapor phase and 50% in the'nonvapor' phase. At near saturation, total diffusion is in the 'nonvapor' phase. The diffusion coefficient for lindane in a Gila silt loam is nearly zero at 1% soil-water content and increases rapidly to a maximal value at 3% water content. Decreasing bulk density or increasing temperature raises the diffusion coefficient. The influence of soil-water content, relative humidity, air flow rate and insecticide concentration on the volatility of lindane from soil surfaces is being determined. The influence of soil type on lindane diffusion is being measured. All of the above information will be combined to predict the fate of pesticide residues in soils.

SUPPORTED BY U.S. Dept. of Agriculture

4.0086, PESTICIDE MOBILITY AND DEGRADATION IN SOIL-WATER SYSTEMS

J.W. BIGGAR, Univ. of California, Agricultural Experiment Sta., *Davis, California* 95616 (CA-D0-WSE-2298-RR)

OBJECTIVE: Identify and characterize the physical-chemical properties of the pesticide-soil-water system which are pertinent to pesticide transport through the soil in infiltrating water, and pesticide desorption from eroded soil into surface waters. Measure pesticide transport through and over soil in the field or in lysimeters, using well characterized initial and boundary conditions.

APPROACH: The thermodynamics of soil pesticide interactions in water will be studied using equilibrium techniques and radioactive pesticides. The kinetic studies will involve dynamic systems both of a steady state and transient nature. Field investigations involve pesticide movement in well defined plots in which water and pesticide movement are monitored over periods of weeks. In some cases, overland flow may be examined in selected watershed areas. The investigators cooperating on this objective will work closely with those developing models to assure the maximum usefulness of field data. California will be making field measurements with the carboxylic acid herbicides on the soils.

PROGRESS: Work has been extended and now completed on the persistence and recovery of four chlorinated hydrocarbons from five California soils involving six extraction methods which include 12 solvent or combinations of solvents. Hexane 2-propanal (1:1) appeared to give the best all-around extraction.

Pesticide loss appeared to follow a first-order reaction. The Hi-ester-Vermuelen rate model for the displacement and removal of pesticides is being examined as a possible useful predictive model for pesticide behavior. Calorimetric results of last year were reexamined and found to be essentially the same with important differences between the Ca and Na-illite systems. Solubility measurements on six organo-phosphate pesticides at 15, 25, and 35 C. have been completed for ionic solution concentrations of 0.01 and 0.05N CaCl(2) and NaCl.

SUPPORTED BY U.S. Dept. of Agriculture

4.0087, RESIDUES OF SELECTED PESTICIDES IN PLANTS, ANIMALS, AND THE PHYSICAL ENVIRONMENT
F.A. GUNTHER, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-R0-SSE-2296-RR)

OBJECTIVE: Establish, evaluate, and integrate the physical fates of selected pesticide chemicals in soils, soil water, root crops, and small aquatic organisms that are involved in food chains; develop necessary analytical methodology for these measurements and characterizations.

APPROACH: Selected currently important pesticide chemicals will be studied by physical-chemical and biochemical methods in 50 soil types in both field and laboratory in terms of sorption kinetics, effects of microorganisms, light, temperature, aeration; or leachability by water; or migration to root crops via soil water suspensions, and their acquisition from soil water suspensions by algae, small shrimp, small fishes, and amphibians.

PROGRESS: The persistence of the herbicide Planavin in different soil types was studied under aerobic and anaerobic conditions. The herbicide was lost rapidly from submerged Hanford sandy loam soil but very slowly from other soil types. Several degradation products have been detected and efforts to identify them are in progress. Irradiation with ultraviolet light yielded two major photodecompositon products that have been isolated but not yet characterized. The decomposition of endrin on 10 different air-dried soils was studied and found to vary widely from soil to soil although quite rapid in all types. The addition of water to moisten the soil prevented the decomposition during the period of the study (96 hours). Carbon-skeleton gas chromatography of DDT and some Aroclors (polychlorinated biphenyls, triphenyls, or mixtures of these) was investigated as a means of differentiating between p,p'-DDT and the Aroclors. The dissimilarity in responses was striking and the procedure offers a simple and reliable means for removing the doubts that arise in many instances where DDT is indicated by gas chromatographic responses, yet there is reason to doubt its presence. The Schechter-Haller colorimetric test was also compared for DDT and the Aroclors. At the wavelength normally used for determining DDT, interference by Aroclors was negligible. This reaction, therefore, affords a reliable supplementary test for the presence of DDT.

SUPPORTED BY U.S. Dept. of Agriculture

4.0088, REACTIONS OF PESTICIDES WITH SOILS
J.P. MARTIN, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-R0-SSE-2406)

OBJECTIVE: Study the incorporation of pesticides into the stable soil humus; the mechanisms of the occasional temporary toxic effects of pesticide in soil; the mechanisms of pesticide absorption and desorption by soil constituents; mechanisms of increases in soluble or extractable inorganic ions in soil following pesticide applications; absorption, transportation, and accumulation of selected pesticides in plants and the influence on plant growth and metabolic functions, and the influence of soil exchangeable cation ratios and metal salts of selected pesticides on decomposition in soil.

APPROACH: The work will involve plant culture in soils and nutrient solutions in the greenhouse and in growth chambers, and soil treatment and incubation in the laboratory. In addition to the usual analytical procedures, gas chromatographic, carbon 14 analysis with a liquid scintillation counter, and infra-red techniques will be used.

PROGRESS: Studies of lindane diffusion at various moisture contents and ambient pressures revealed that diffusion occurred along four major pathways: air-space, air-water interface, water-water pathway, and water-solid interface. The vapor and water-water pathway components were readily described by normal gaseous equations, and ion diffusion equations, respectively. The quantity diffusing along the air-water interface was proportional to the area of the air-water interface. Volatilization loss of dieldrin from Gila silt loam increased with increasing concentration, air flow rate, relative humidity, soil water content, and temperature. Losses ranged from 4mg/cm/day up to 600mg/cm/day. Maximum dieldrin loss occurred at 100% relative humidity when no water loss was occurring from the soil. Thus water loss is not necessary for dieldrin volatility to occur. The ratio of DDT:dieldrin:lindane loss was 1:5:17 for both 5 and 10 ppm at 30C. The volatility results indicate that potential insecticide losses under field conditions due to volatilization may account for a significant proportion of the total loss. Methods of reducing DDT levels in contaminated agricultural fields are under investigation. In one case, deep plowing to 24 inches has been used to dilute the insecticide and to remove it from the root zone. Soil and crop samples are being analyzed as a measure of the method's effectiveness.

4.0089, FATE AND EFFICACY OF SOIL FUNGICIDES
D.E. MUNNECKE, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-R0-SSE-2086)

OBJECTIVE: Fate of fungicides in soil; factors influencing effectiveness of soil fungicides in controlling plant diseases; nature of fungicide detoxification in soil and effects of various breakdown products on fungi and plants.

APPROACH: Laboratory studies will be made on nature of breakdown products of fungicides in soil. Use will be made of existing equipment such as ultra violet and infrared spectrophotometers, chromatographic techniques, and other specialized apparatus. A constant temperature growth chamber has been built to provide controlled growing conditions. Occasionally, experiments will be conducted in greenhouses and in field.

PROGRESS: U.C. mix infested either with Pythium ultimum or Rhizoctonia solani was fumigated with 600, 1200, or 2300 ppm methyl bromide gas to measure the effects of varying soil moisture on the effectiveness of the fumigant in controlling damping-off of peas. With Pythium best control was obtained in moderately moist soil (12% water), next in the very wet (37%), and least in the very dry (12%) soil. Exposures for 1 day at all 3 concentrations were mostly ineffective. This ineffectiveness carried on into the 2 day exposures for doses of 600 and 1200 ppm, but not for doses of 2300 ppm. After exposures of 5 or 8 days, very steep dosage response curves were obtained, perhaps indicating extreme susceptibility of Pythium to methyl bromide. The control of Pythium in dry (2%) soil was poor. Probably a dose of 18,000 ppm applied for 8 days would reduce damping-off to only 5%. The response of Rhizoctonia was similar. Best control was found in soil containing 10% moisture, slightly better control was obtained in the very dry soil and least was observed in the very wet soil.

SUPPORTED BY California State Government - Sacramento

4.0090, REACTIONS OF PESTICIDES WITH SOILS IN RELATION TO SOIL PRODUCTIVITY IN THE SOUTHWEST
W.F. SPENCER, Univ. of California, U.S.D.A. Soil & Wa. Cons. Div., *Riverside, California* 92507 (SWC-024-GRI-3)

OBJECTIVE: Determine the magnitude and method of chlorinated hydrocarbon insecticides in soils and to evaluate the influence of soil properties, temperature, humidity, and soil-water content on movement, particularly vapor-phase movement, and volatilization losses into the atmosphere.

APPROACH: Laboratory experiments will be conducted to ascertain the physical and chemical properties of chlorinated hydrocarbon insecticides and other pesticide materials, and evaluate the influence of various soil factors affecting their interactions with soils and waters. Commonly used pesticides will be applied under controlled conditions to semiarid soils. Predictions will be developed from measuring movement, volatilization losses, magnitude of absorption and breakdown products under controlled environmental conditions. Movement, redistribution,

and volatilization of pesticides will be evaluated under actual field conditions to verify these predictions.

PROGRESS: Relationship between soil properties and vapor density of soil applied dieldrin indicated that vapor densities were inversely related to the soil organic matter content, both in wet and dry soils. Ten ppm dieldrin was required to produce a saturated vapor in a soil containing 67% clay. This indicates that clay plays only a minor role in absorption of such weakly polar compounds when sufficient water is present to cover the mineral surface. Vapor-phase desorption isotherms relating soil lindane concentration to relative vapor density were similar to isotherms relating soil lindane concentration to the solution concentration. Dieldrin volatilization was not affected by fluctuating the pressure of the gas flowing over the soil surface. Volatulization rate over a 29-day period indicated that rate of loss was initially dependent on vapor density at the soil surface but rapidly became a diffusion controlled process. Soil samples taken at various depths in plots treated with dieldrin and lindane indicated that lindane moved and disappeared from the soil much more rapidly than dieldrin. Concentration gradients at the surface of irrigated plots indicated that dieldrin and lindane were lost by volatilization from the surface. Lindane was probably also lost by decomposition.

4.0091, INTERACTION OF TEMPERATURE WITH OTHER FACTORS ON RESPONSE OF CANADA THISTLE TO HERBICIDES

J.L. FULTS, Colorado State University, School of Natural Sciences, *Fort Collins, Colorado* 80521 (COL00216)

OBJECTIVE: Determine the relationship of temperature to the action of herbicides as influenced by external factors such as light, moisture, nutrients, the physical and chemical properties of herbicides, and adjuvants; the relationship of temperature to the action of herbicides as it interacts with internal factors such as cellular metabolites and cellular particulates at the tissue and cellular level.

APPROACH: Three selected clones of Canada thistle will be used as basic research material for experimentation by all participating states. Will determine the overall response of resistant and susceptible strains of Canada thistle using temperature x light quality and intensity combinations in growth chambers.

PROGRESS: General difficulties have been encountered in culturing thistle. Other test plants have been used. In a study of pyrazon and its herbicidal residues in the soil it was found that under growth chamber conditions, soil temperatures at 3 and 6 inch depths parallel ambient air temperatures; soil temperatures in the field at the same depths while showing diurnal variations change much more slowly than those in pots in a growth chamber. Under cool moist conditions (17 C) successive plantings of beets in pyrazon treated soil did not result in toxicity but under warm moist conditions (25 C) successive plantings resulted in greatly increased toxicity. Successive plantings of mustard into steamed and raw soil maintained at favorable conditions for plant growth, good aeration and at a favorable moisture level, indicated no evident change in the rate of degradation of pyrazon in either raw or steamed soil up to 3 months. But after 4-1/2 months remarkable differences appeared. In the raw soil pyrazon toxicity disappeared but toxicity persisted in the steamed soil. In a study of dicamba and picloram behavior in soil both proved to be more active in the liquid phase than in the vapor phase. Probably the most important physical characteristic in 15 Colorado soils associated with toxicity of these soil-applied chemicals is organic matter content. Both chemicals are detoxified more rapidly under high than under low temperatures in soil, dicamba detoxifying much more rapidly than picloram when both are originally present at equitoxic concentrations. Dicamba follows a first order rate of dissipation.

4.0092, INSECTICIDE DECONTAMINATION OF COLORADO SOILS BY UTILIZATION OF ANIMAL WASTES

R.E. JOHNSON, Colorado State University, Agricultural Experiment Sta., *Fort Collins, Colorado* 80521 (COL00012)

OBJECTIVE: Examine animal wastes as energy for and source of microorganisms for biodepredation of chlorinated hydrocarbon insecticides in soil.

APPROACH: Chlorinated hydrocarbon insecticides will be added to insecticide-free soil in Erlenmeyer flasks in measured amounts. To these flasks will be added samples of manure and sewage sludge and the flasks stored for various periods of time at the end of which they will be analysed for insecticide content. From samples found low in insecticide, microorganisms will be isolated and multiplied in both and insecticides added, the broth incubated for 96 hours, and then analysed for insecticide content.

PROGRESS: Preliminary studies used a Colorado loam soil treated with 200 ug p,p'0DDT and incubated at various dose levels with cattle manure for periods of 1 week, 1 month and 2 months at two moisture levels, saturated and unsaturated. DDT was converted primarily to TDE with an excellent correlation between amount of manure added and conversion to TDE. With no manure and at the lowest manure rate, there was a negligible to low conversion, respectively. The other levels showed no parent DDT remaining. Moisture level was important only at the low manure level where the saturated condition accelerated the degradation of DDT. At the high manure level for all periods all the DDT was degraded. Several unknown metabolites were found and need to be identified.

SUPPORTED BY U.S. Dept. of Agriculture

4.0093, CHLORINATED PESTICIDES IN THE SOIL-WATER-PLANT SYSTEM AND THEIR MANAGEMENT TO AVOID POLLUTION

F.G. VIETS, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Fort Collins, Colorado* 87101 (SWC-024-DFC-6)

OBJECTIVE: Determine the effects of soil type, temperature, organic matter, pH, aeration, and water content on the persistence, absorption, and movement of chlorinated pesticides in the soil-water system and on plant growth for the development of better systems of soil and water management and decontamination for the Northern Plains.

APPROACH: Chlorinated pesticides are added to natural and amended soils, clay minerals, and soil organic fractions with variables of pH, water content and movement, oxygen supply and other conditions and the absorption, rate of loss, degradation products, and movement under leaching conditions measured by chemical techniques. Mechanisms and rates of volatilization and effects on soil metabolism are measured. Soil and water samples from experimentally treated plots, watersheds and fields are analyzed for accumulation and rates of loss of pesticides.

PROGRESS: Evidence obtained to support earlier findings that adsorption of DDT is strongly influenced by positively charged particles. DDT which remained in the aqueous phase of sedimented soil- DDT systems was directly proportional to the amount of soluble and colloidal soil organic matter which resulted from sedimented soil. Various phenolic compounds which are water-soluble components of soil organic matter, significantly increased solution phase DDT when concentrations 0.1 mug of the phenolic compounds per ml. of water existed. Under aerobic conditions in a lab. study, rate of DDT conversion to DDE was greater at 50 C. than at 30 C. Soluble iron addition had no effect. After 140 days, the amount of DDE resulting from DDT degradation was 7.5 times greater at 50 C. than at 30 C. DDT was converted to DDD in anaerobic soil (submerged). Iron addition had no effect on the conversion process. After 10 days, about half the DDT was degraded at 30 C. and about 90% of DDT was degraded at 50 C. In a field study, no effect of soil mixing or added alfalfa observed in disappearance of dieldrin, endrin, DDD, and DDT from the top 8 cm. of soil during 22 weeks of treatment. Under same conditions, concentration of lindane and heptachlor decreased with time, and more pesticide was lost from soil receiving mixing treatment than from nonmixed soil.

4.0094, MOVEMENT AND ADSORPTION OF PESTICIDES IN STERILIZED SOIL COLUMNS

R.S. MANSELL, Univ. of Florida, School of Agriculture, *Gainesville, Florida* 32601

The objective is to determine the influence of soil and carrier solution properties on adsorption, dispersion coefficient and rate of movement of pesticides, detergent surfactants, hydrophobic surfactants and tritiated water in sterilized soil columns at various degrees of saturation and flux.

Soils sterilized by gamma radiation will be set up in columns (10 cm cube, sides enclosed with acrylic plastic) for miscible displacement of tritiated water and radioisotope-tagged pesticides and surfactants. Inflow and outflow will be through porous fritted-glass plates in contact with the top and bottom of soil columns. Filtered gas, under variable pressure, will be admitted through the sides of the container to establish the desired degrees of unsaturation. A Sigmamotor pump will control flux of solutions having different surface tensions.

A flow cell in connection with a three-channel analyzer for beta spectrometry will form a liquid radiochromatography system for the nondestructive detection, analysis and recording of the radioactive chemicals eluting from the soil column.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

4.0095, THE DISPOSITION OF PESTICIDES IN THE SOIL
D.R. ROTHWELL, Univ. of Florida, Agricultural Experiment Sta., *Gainesville, Florida* 32601 (FLA-SL-01317)

OBJECTIVE: Determine the physical, chemical, and biological processes, and soil characteristics which are important in the disposition of pesticides in soils.

APPROACH: Emphasis will be on the determination of the effect of pesticides on the growth of soil organisms and their metabolic processes and the effect of soil organisms on the degradation of pesticides. Soils with widely varying properties will be selected and treated with pesticides. Relative number of bacteria, fungi, actinomycetes, algae and nematodes will be determines by dilution techniques. Untreated soils and soils previously treated with pesticides will have known quantities of the same pesticide added to them. The relative rates of disappearance of the chemicals will be followed.

PROGRESS: Several kinds of pesticides are used regularly on shade tobacco throughout the growing season. These pesticides enter the soil either by direct application or as residue from foliage applications. Combinations of these pesticides may affect microbial activity in the soil. Persistence of the pesticides may also be affected. The chemical compounds Zineb, DDT, Parathion, and Furadan have been selected for evaluation singly and in combination. Application rates will be 1.3, 2.0, 0.2, and 10 lbs. per acre, respectively, of the active ingredient applied in 12 weekly applications. The soils will be sampled at 2 week intervals. A randomized block design will be used. These investigations will be conducted under field and greenhouse conditions. Data are not yet available.

4.0096, PRELIMINARY EXPLORATORY CITRUS RESEARCH AT CITRUS EXPERIMENT STATION
J. HERMAN, Citrus Agricultural Expt. Sta., *Lake Alfred, Florida* 33850 (FLA-CS-00001)

OBJECTIVE: Investigate new problems in the citrus industry.

APPROACH: Preliminary surveys, exploratory investigations, and short-term trials will be conducted on citrus industry problems.

PROGRESS: Blight, a tree decline of unknown cause, became much more prevalent in 1967 and 1968. Intensified research to establish the cause failed to associate Blight with bud-transmissible virus disease, fertilizer program, soil salinity, fungi, or nematodes. A severe tree decline peculiar to the Murcott mandarin variety was attributed to an unusual stionic effect whereby the rough lemon rootstock was relatively ineffective in supplying heavy Murcott crops with adequate N and K. Increased N and K fertilization is indicated as a corrective. Residues of Temik systemic pesticide applied to the soil were present to a depth of over 3 feet for at least 31 weeks after application. Maximum concentration of Temik in fruit occurred about 33 weeks after application. Quantitative methods for determination of some carotenoids in peel of citrus fruits were worked out. NAA successfully thinned tangerines in preliminary work.

SUPPORTED BY Florida State Government - Tallahassee

4.0097, DEVELOPMENT OF IMPROVED PRINCIPLES AND CHEMICAL AND COMBINATION METHODS FOR CONTROLLING WEEDS IN COTTON ON COARSE TEXTURED SOILS
E. ELSNEP, Univ. of Georgia, Agricultural Experiment Sta., *Athens, Georgia* 30601

Problem & Need: Much of the cotton in the Southeast and some in other parts of the Belt is grown on deep sandy loams, loamy sands, and sands. Because of their low clay content and, oftentimes, low organic matter - the latter being especially true under well drained conditions - these soils have rather low capacities to absorb and retain chemicals such as herbicides. Also, they are often rather deep porous soils which, coupled with high rainfall, makes them subject to rapid leaching of applied chemicals. In addition, these conditions enhance losses in herbicide efficiency through volatilization and photodecomposition.

Presently there is not an efficient and safe chemical practice for controlling weeds in cotton on deep, coarse soils.

The Research: Studies should be undertaken to develop and evaluate preplanting, preemergence, and postemergence chemical weed control practices for cotton in deep, coarse-textured soils, especially those under high rainfall conditions. Special attention should be given to (1) weed control requirements based on ecological, cultural, edaphic and climatic conditions, (2) the use of new forms and formulations such as slow-release type materials, (3) integration of herbicides with other production practices, and (4) the interactive roles of other soil applied pesticides as they affect the behavior of herbicides in coarse soils. Special attention will be required on various aspects of soil behavior of herbicides including adsorption by clay fractions, leaching movements, microbial breakdown, etc.

SUPPORTED BY Cotton Incorporated - Raleigh, N.C.

4.0098, THE DISPOSITION OF PESTICIDES IN THE SOIL
J.E. GIDDENS, Univ. of Georgia, Agricultural Experiment Sta., *Athens, Georgia* 30601 (GEO00382)

OBJECTIVE: Determine the distribution of pesticides in selected soils and their drainage waters using sites to which known amounts of pesticides have been applied. Determine the physical, chemical and biological processes, and soil characteristics which are important in the disposition of pesticides in soils.

APPROACH: By soil perfusion and other techniques, breakdown rate of herbicides as influenced by soil properties and enriched microorganisms will be determined. Herbicidal effect upon rhizosphere organisms and effect of rhizosphere organism on herbicides will be determined. Specific root infecting fungi will be inoculated into the root zone in presence and absence of herbicides and their behaviour studied. Herbicidal effects upon soil processes as nitrification, N- fixation, and S-transformations will be studied.

PROGRESS: Trifluralin volatilization rate was high from moist soils but low from dry soils. Application of water to soil at different bars indicated high trifluralin loss from soil when moisture approached field capacity. Moisture application prior to trifluralin application resulted in greater herbicides volatilization than when herbicide was applied to dry soil then wetted. Further work continued to show the mitotic effect of trifluralin on plants but no effect on oxidative phosphorylations.

SUPPORTED BY U.S. Dept. of Agriculture

4.0099, DISPOSITION OF PESTICIDES IN THE SOIL
R.M. HARRISON, Georgia Agric. Expt. Sta., *Griffin, Georgia* 30212 (GEO00195)

OBJECTIVE: Determine the distribution of pesticides in selected soils and their drainage waters, using sites to which known amounts of pesticides have been applied. Determine the physical, chemical, and biological processes, and soil characteristics which are important in the disposition of pesticides in soils.

APPROACH: The distribution of selected pesticides will be determined by applying them to small, level, fallow, plots located

on undisturbed profiles of differing soils of the Georgia Piedmont. Plots will be enclosed to retain rain which falls on a given plot and to prevent pesticide movement from plot to plot. At intervals, the profiles will be sampled to as much as five feet. Studies will later be extended to cropped soils. The pesticidal effect on mineralization and nitrification in unfertilized samples and in samples fertilized with an ammoniacal source, will be studied in the laboratory.

PROGRESS: Soil samples taken from a two year field study previously described have been analyzed by gas chromatography for trifluralin, Aldrin, and Endrin. No downward profile movement of the three pesticides below a 6 inch depth was found in the well drained Cecil soil site and the imperfectly drained Iradell soil. Trifluralin was previously shown to be absent after 10 months. Over 50 percent of Aldrin and Endrin remained in the soil over the two year period. A major portion of Aldrin was degraded into dieldrin and Endrin was partially altered into a compound not identified. Additional research has not been undertaken as the project has been terminated. A technical paper on the soil extraction of trifluralin is being reviewed for publication and a second paper on the field research is presently being written.

SUPPORTED BY U.S. Dept. of Agriculture

4.0100, PESTICIDES IN SOILS AND WATERS OF THE SOUTHERN PIEDMONT

A.W. WHITE, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Watkinsville, Georgia* 30677 (SWC-024-BAW-03)

OBJECTIVE: Determine the important pathways of pesticide loss from soils and waters, including the magnitude of losses by runoff and erosion, volatilization, and decomposition; determine the mechanisms involved and conditions that influence pesticide persistence and losses from soils and waters; and develop methods and field practices for minimizing the polluting effects of pesticides on soil and water resources.

APPROACH: The extent and mechanism of pesticide losses from soils and waters by various pathways will be determined in field and laboratory experiments. Movement of pesticides over and through the soil will be evaluated under natural and artificial rainfall conditions. Environmental conditions and soil factors that influence persistence and loss of pesticides from soils and waters will be determined. The effect of management systems on soil and water quality will be evaluated and new systems will be developed for minimizing the polluting effects of pesticides on soil and water quality.

PROGRESS: Results from 96-day oven incubation studies showed that the chlorinated insecticides lindane and dieldrin disappeared from Cecil soil at appreciable rates under warm dry conditions. The half-life values for 0.5 to 5.0 ppm lindane in dry Cecil sandy loam at 45 and 65 were 50 and 13 days, respectively. Under the same conditions dieldrin was approximately ten times more persistent than lindane. The observed disappearances followed first- and second-order rates, and equations were derived for estimating lindane and dieldrin persistence in soil with time at 45 and 65 . At room temperature no loss of either pesticide was measured. It appears that a significant part of the lindane and dieldrin disappearance in warm dry soils observed in these experiments may be due to catalytic degradation. Significant degradation was found at 45 and 65 in the case of lindane as evidenced by the appearance of pentachlorocyclohexene, a reported lindane degradation product. Further evidence of lindane degradation was indicated by the release of significant levels of chlorides in warm dry soils and clays. Degradation was retarded by small amounts of moisture and by organic matter, and was enhanced by the presence of free ion oxides.

SUPPORTED BY U.S. Dept. of Agriculture

4.0101, HERBICIDE EQUILIBRIA OF LATOSOLIC SOIL

R.E. GREEN, Univ. of Hawaii, Agricultural Experiment Sta., *Honolulu, Hawaii* 96822 (HAW00127)

OBJECTIVE: Relate the adsorption and desorption of organic herbicides to the chemical and physical properties of Hawaiian soil. Determine the importance of microbial degradation of herbicides. Determine the effect of soil pore-size distribution and associated soil- water relations on herbicides equilibria in soils and absorption by plant roots.

APPROACH: Adsorption will be characterized by measurement of herbicide adsorption on soils or soil separates from aqueous solution of the herbicide. An attempt will be made to identify the 'active' fraction of the organic matter or the clay-organic complex and to measure the partition coefficient of this fraction. In the field, particular attention will be given to the longevity of weed control in sugarcane at various rates of s-triazine herbicides. In the laboratory, C tagged herbicides (primarily s-triazine compounds) will be used to study (a) gross degradation of herbicides, and the nature of degradation deaminization, in relation to the availability of energy sources (including plant roots) and water.

PROGRESS: Simazine and atrazine hydrolyzed faster than ametryne and G.S.-14254 (sumatol) at any given pH in four Hawaiian soils. The rate of hydrolysis of triazines was inversely related to the soil pH. The magnitude of the pH-effect was highly dependent on soil organic matter content. The catalysing effect of soil on hydrolysis was quantified by calculations based on dividing the process into two steps -- protonation (pH-dependent) and hydrolysis of the protonated species (temperature dependent). Adsorption on charcoal decreased the rate of hydrolysis while soil organic matter accelerated hydrolysis, an important consideration on sugar cane soils having relatively high quantities of charcoal from cane burning. Adjustment of soil pH by liming may provide a means of manipulating triazine response on some soils. Atrazine was detoxified in soil both by chemical hydrolysis and by microbial removal of the ethyl-chain. The hydrolysis product (hydroxyatrazine) was metabolized, with subsequent evolution of CO(2); the dealkylated chloro-triazine is thought to be persistent. Complete biological breakdown of atrazine to CO(2) must be preceded by chemical hydrolysis at the 2-position. Thus, plant species or soils that bring about rapid hydrolysis at the 2-position will accelerate ring cleavage, i.e. total triazine degradation.

SUPPORTED BY U.S. Dept. of Agriculture

4.0102, SOILS, PESTICIDES AND THE QUALITY OF WATER

G.C. LEWIS, Univ. of Idaho, Agricultural Experiment Sta., *Moscow, Idaho* 83843 (IDA00516)

OBJECTIVE: Identify and characterize the physical-chemical properties of the pesticide-soil-water system which are pertinent to pesticide transport through the soil in infiltrating water, and pesticide desorption from eroded soil into surface water. Identify the principal degradation products and determine the mechanisms and kinetics of pesticide transformations in soil-water systems.

APPROACH: Adsorption-desorption equilibria of organophosphate pesticides in relation to the chemical properties of soils will be studied. The effect of various soil constituents on the degradation of the pesticides will be investigated. Decomposition studies will be carried out in sterile and non-sterile soil systems; degradation rates and end products will be determined.

PROGRESS: The adsorption isotherm of Di-Syston onto a southern Idaho soil (Portneuf Silt Loam) was determined. An S-shaped isotherm was obtained. A gas chromatographic technique was developed to separate and detect Di-Syston and its related compounds. Di-Syston Di-Syston, Di-Syston sulfone, and Systox (both isomers) were separated and detected at one temperature setting, while Di-Syston sulfoxide, Systox sulfoxide (both isomers), monoethyl phosphate, and diethyl phosphate were separated and detected at a different temperature setting. With the development of separation techniques it was possible to follow the rate of degradation of Di-Syston and its metabolites in the soil and determine whether degradation products of significance were formed. The degradation of the Di-Syston in the Portneuf soil was found to follow first-order kinetics and 50% of the added amount was degraded in 6.5 days under the conditions of optimum moisture and temperature. The most notable metabolites were Di-Syston sulfone and sulfoxide. The sulfone persisted for over 69 days while the parent Di-Syston was negligible after about 32 days. This indicated that the breakdown of Di-Syston sulfone was probably the rate limiting step in the conversion of Di- Syston to nontoxic products. The presence and persistence of the sulfone may be quite significant as the sulfone is probably more toxic than its parent compound, Di-Syston. Thus, the total toxicity may not have decreased in direct proportion to Di-Syston disappearance.

SUPPORTED BY U.S. Dept. of Agriculture

4.0103, WEED CONTROL ON THE NON-IRRIGATED LANDS OF IDAHO

C.I. SEELY, Univ. of Idaho, Agricultural Experiment Sta., *Moscow, Idaho* 83843 (IDA00131)

OBJECTIVE: Devise effective and inexpensive means of eradicating or controlling weeds; Determine the effectiveness of cultural practices, cropping systems, competing crops and additions of commercial fertilizers on the control of weeds; the effects of various chemicals applied under varying conditions and at different rates. Evaluate new methods and materials for weed control; Study the effects of cultural and cropping, cultural and chemical, and cropping and chemical methods on control and time required to effect control or eradication. Determine the effects of the above on the soil, and study the biology of weeds including the storage of root reserves, methods of dissemination, development of seedlings and the destruction of seed in the soil.

APPROACH: The work will use field plots and selected fields infested with important weeds. Preliminary work on new methods and materials will be done in the laboratory and greenhouse before application to field plots. Laboratory and greenhouse tests will be applied in the evaluation of the effects of the treatments on the soil.

PROGRESS: The 1969 season was relatively unfavorable for winter wheat but there was still 300,000 acres treated with diuron and other residual herbicides with an increase of about 8 bu. per acre over 2,4-D applications. Maloran, another substituted urea, shows promise of being an equally good herbicide with greater safety to the wheat. Twelve annual applications of 1 pound of diuron per acre has not shown any residual build up in the soil. Even a 2 pound rate has shown little if any residual chemical present. Applications of diuron to the 1969 Austrian winter pea crop gave good weed control and increased yields by about 25 percent (600 pounds per acre). Tests of corn spurry seed in the soil have shown that after 10 years of cropping without weed seed production, slightly more than 98 percent of the weed had been eliminated. In a wheat-pea rotation of the control of wild oats increases the number of broadleaved annuals present but that the reverse is not true. For maximum production of wheat both wild oats and broadleaved weeds must be controlled in the preceding pea crop as well as the current crop.

SUPPORTED BY Idaho State Government

4.0104, ANNUAL WEED CONTROL IN ROW CROPS

P.J. TORELL, Univ. of Idaho, Agricultural Experiment Sta., *Moscow, Idaho* 83843 (IDA00526)

OBJECTIVE: Investigate the use of mid-summer fallow treatments as a means to reduce the annual weed seed population in the soil prior to the production of an onion crop. Study the influence of preemergence and postemergence herbicides registered for use in onions on the annual weed population that survives a mid-summer fallow, the influence of preemergence herbicide treatments on the control of annual weed in onion seed crops with special reference to layby weed control; the influence of peemergence herbicide treatments on the control of annual weeds in hybrid sweet corn crops.

APPROACH: The work will be conducted along two lines:For each crop investigations will be conducted to determine the most effective herbicides, rate, time, and method of application for annual weed control. Second, the fate of annual weed seed populations in the soil as influenced by a mid-summer fallow in the year preceding the row crops in question will be studied.

PROGRESS: Some 95 percent of the nation's sweet corn seed is grown in southwestern Idaho. Thus the crop occupies a relatively large acreage and it is important to the economy of the area. Labor costs make control of weeds by herbicides imperative. But the herbicides presently used in corn leave residues in the soil that damage other crops such as sugar beets which follow corn. A new herbicide, alachlor, appears promising as a means to alleviate this difficulty. Soil residue studies conducted in 1968 and those in progress for 1969 indicate that alachlor will not persist beyond the crop year of its use. The chemical gave satisfactory season-long control of annual weeds at rates that did not damage the corn stand, seed yield, or seed germination. Another new herbicide, chloroxuron, gave good control of annual weeds in onion seed crops. The chemical was most effective on weeds and most selective to onions when used with a wetting agent and applied as a directed spray.

SUPPORTED BY Idaho State Government

4.0105, LONG-TERM EFFECTS OF DIFFERENT SYSTEMS OF WEED CONTROL IN CROP ROTATIONS ON ECOLOGY AND CROP PRODUCT

F.R. SLIFE, Univ. of Illinois, Agricultural Experiment Sta., *Urbana, Illinois* 61801 (ILLU-15-0396)

OBJECTIVE: Study effect of rotation herbicides and crops on ecological changes in weed populations; on the fate of herbicides in the soil and on the biological, physical and nutritional status of the soil.

APPROACH: Field plots were established in 1965 and have been managed in accordance with a rotational plan for crops and for herbicides. Data has been taken annually on crop and weed yields. A detailed analysis of weed seed populations, residues, effects on micro- organisms and the yield of crops under each cropping system will be made at end of 1970 harvest when two complete cycles of the three year rotation will have been completed. These studies will continue over a long-term basis.

SUPPORTED BY Illinois State Government - Springfield

4.0106, STRUCTURAL CHEMISTRY OF SOIL HUMIC SUBSTANCES

F.J. STEVENSON, Univ. of Illinois, Agricultural Experiment Sta., *Urbana, Illinois* 61801 (ILLU-15-0339)

OBJECTIVE: Determine the structural arrangement of functional groups in humic acids and related pigments, characterize nitrogenous constituents associated with humic substances.

APPROACH: A study will be made of oxygen-containing functional groups (carboxyl, phenolic hydroxyl, enolic, quinone, alcholic hydroxyl) involved in: base exchange, chelation, and buffering reactions in soil, binding of primary minerals into stable aggregates, and retention of herbicides, insecticides, and pesticides. In addition, free amino groups and structural nitrogen linkages will be determined.

PROGRESS: The humic fraction of the organic matter in select Illinois soils was found to consist of a whole series of acidic, yellow to black colored, moderately high molecular-weight pigments which varied in a systematic way in elemental composition, acidity, degree of polymerization, and molecular weight. The strongly acidic yellow pigments had characteristics similar to those reported for 'yellow complexes' in natural waters. Infrared examination of derivatives produced by methylation (methanolic-HCl, diazomethane, dimethyl sulfate) and reduction (diborane, lithium aluminum hydride) revealed the following: (i) the methods commonly used to estimate COOH, acidic (phenolic) OH, alcoholic OH, and C0O groups in soil humic substances are nonspecific and yield values of questionable accuracy, (ii) the COOH groups of the so-called humic acids originate from side chains of an aromatic ring whereas those of the so-called fulvic acids have been formed largely by partial oxidation of phenolic and/or enolic moieties, and (iii) the greater mobility of fulvic acids than humic acids in soils and sediments is due to a combination of lower molecular weight and higher concentration of acidic functional groups, particularly COOH. Confirmation was obtained for the observation (1968 progress report) that the techniques commonly used to block specific functional groups in connection with studies on the mechanism of adsorption of herbicides and other agricultural chemicals by soil organic matter lead to results which must be interpreted with extreme caution.

4.0107, SOIL FUMIGANT CHEMICALS AND THEIR EFFECTS ON SOIL MICROFLORA

C.B. KENAGA, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (IND01626)

4. PESTICIDES

OBJECTIVE: Microbial selectivity; population dynamics; interaction of dosage rate and inoculum density, and factors influencing the depth of penetration; and mechanism of synergism of fumigant chemicals.

APPROACH: Standardize soil type, moisture and compaction; Use stabilized populations of microflora, among which are, pathogens and antagonists; Use stoppered polyethylene tubes as test containers; and Assay microflora for viable fungi, varying time after treatment and soil depth. Establish vapor diffusion patterns through soil columns for chemicals, alone and in combination, by means of a gas chrommatograph.

PROGRESS: Investigations have been initiated relevant to syngergistic chemical soil fumigants under investigation and pertinent literature has been screened and listed.

SUPPORTED BY U.S. Dept. of Agriculture

4.0108, SOIL INVERTEBRATES INFLUENCE ON CORN RESIDUES

J.V. OSMUN, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (IND01567)

OBJECTIVE: Determine the role of soil invertebrates in the breakdown of corn residues; investigate the interrelations among plant density-crop residue-soil invertebrates; investigate influence of cultivation; relate crop residues to pest populations; observe pest populations under increased plant densities and minimal cultivation; determine influence of crop residues on insecticide persistence.

APPROACH: An experimental site will be developed in an area where corn has not been grown previously and where soil insecticides have not been used. Standard and developing corn growing practices will be undertaken with the variables; cultivate-minimal tillage; differing plant populations; plots defaunted with insecticides - no treatments. The rate of crop residue breakdown will be determined and the role of soil invertebrate will be assessed by periodic sampling.

PROGRESS: The last crop in this three-year experiment was sown and the soil was treated as in previous years to manipulate the soil fauna to determine the effects of insecticides, cultivation and crop density on plants debris build-up in fields continuously in corn. Insecticide and plant residue samples and arthropod counts will be taken until June 1970, the termination date of the project. Available data are with Dr. Clive Edwards at Rothamsted for eventual summary and evaluation.

SUPPORTED BY Indiana State Government

4.0109, CHARACTERIZATION OF SURFACES OF CRYSTALLINE AND AMORPHOUS SOIL COLLOIDS

J.L. WHITE, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (IND01224)

OBJECTIVE: Characterize the surfaces of colloidal crystalline and amorphous soil materials.

APPROACH: Infrared and x-ray diffraction techniques will be used to identify crystalline colloids and relate surface properties to structure and chemical composition. The presence, extent and nature of the reactive surfaces of amorphous colloids will be studied by infrared measurements of water and ammonia absorption, and measurement of rate of fluoride complexation of reactive aluminum at surfaces with a fluoride specific ion electrode.

PROGRESS: Infrared studies of hydrogen bonding in clay-adsorbed water in hydronium-saturated micaceous clays have revealed stronger hydrogen bonding; infrared OH stretching frequencies of 1940 cm---1, corresponding to 0-0 distances of 2.47 A., have been observed. Similarities between properties of clay-adsorbed water and those of polywater have been described. Observations provide a better basis for understanding mechanism of bonding of pesticides to soil surfaces as well as the origin of 'surface acidity' which strongly affects the adsorption and degradation of pesticides. A computer library of crystal structure programs for x-ray diffraction analysis of cation positions and water structure in the interlayer region of vermiculite has been developed. Degradation of 12 s-triazine herbicides by montmorillonitic soil clays under natural conditions has been demonstrated by infrared spectroscopy. Highly acidic environment of the clay surface was shown to cause degradation by protonation and chemical hydrolysis. The degraded herbicide is held tightly by the soil colloid so that it is unlikely to enter the ground water to any significant extent.

SUPPORTED BY U.S. Dept. of Agriculture

4.0110, PESTICIDE-SOIL COLLOID INTERACTIONS

J.M. WHITE, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (IND01179)

OBJECTIVE: Study the mechanism of adsorption of pesticides by soil colloids; determine changes in structure and biological activity of pesticides induced by adsorption on soil colloids; examine the kinetics of adsorption and desorption of pesticides on soil colloids; study the relationship between chemical character of pesticides and retention by soil colloids.

APPROACH: The mechanisms of adsorption will be studied by x-ray diffraction and infrared techniques; changes in structure and biological activity of pesticides when adsorbed by colloids will be studied; kinetics of adsorption and desorption will be studied by gas chromatography; the influence of chemical character of pesticides on adsorption by soil colloids will be examined.

PROGRESS: The role of chemical character of herbicide compounds and pH in adsorption of herbicides by montmorillonite has been evaluated for 18 members of herbicide families which include s-triazines, substituted ureas, phenylcarbamates, anilides, phenylalkanoic acids, benzoic acids, and picolinic acids. We have shown that the surface acidity of the clay mineral may be 3 to 4 pH units lower than the bulk pH; the pesticides may be profoundly altered in such an environment and the mechanisms of absorption and degradation proposed to be operative at the bulk pH are not applicable. Infrared studies of the interactions of 3-aminotriazole and the s-triazines with the montmorillonite surface have shown that these herbicides are protonated and converted to cations at the clay surface. These studies have also established the mode of chemical degradation and detoxification of the s-triazines by montmorillonite and montmorillonitic soil clays. An understanding of the mechanisms of adsorption and detoxification of the s-triazines should make possible modifications in mode of application so as to maximize effectiveness and minimize residual effects. Future studies are planned on behavior and movement of cationic forms of 3- aminotriazole and s-triazines in soils, and relationships between electronic structure of herbicides as revealed by nuclear magnetic resonance spectra and the nature of the interaction between the herbicide and the aluminosilicate surfaces.

4.0111, EQUIPMENT AND TECHNIQUES FOR WEED CONTROL

W.G. LOVELY, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010 (IOW01815)

OBJECTIVE: Determine distribution, placement, and accuracy of metering, to reduce amount of herbicide needed for effective control and develop the necessary equipment and methods. Develop equipment and techniques for improving weed control with nonchemical methods. Develop an analysis technique to evaluate weed control equipment and methods as part of a crop production system.

APPROACH: Laboratory and field experiments will be conducted. In addition to the standard approach, herbicide distributions will be measured using gas chromatograph, spectrophotometry, and bioassay. Weather data and job completion probabilities will be used for system analysis.

PROGRESS: Timely rotary hoeing and mechanical cultivation on conventionally tilled soil for corn and soybeans gave excellent weed control. Using preemergence herbicides made timeliness less important and eliminated the need for some mechanical operations. Overall applications of early postemergence sprays were more effective than directed sprays. Three flamings with the air-curtain flamer were required to obtain satisfactory weed control. Preplant herbicide applications gave effective weed control for minimum tillage systems. Using shallow cultivating tools with more soil action than rotary hoes 5 to 10 days after weeds emerged gave effective weed control in corn and soybeans. Preemergence spray applications of herbicides at

recommended and 2 X recommended rates gave poor weed control for no-plow tillage systems for corn. Weeds were successfully controlled in continuous soybeans without tillage by using preplant applications of paraquat and preemergence applications of trifluralin, amiben, or alachlor. Movement of atrazine with soil and water was substantially greater for conventional tillage than from ridge planting. Rotary hoeing improved the effectiveness of corn and soybean preemergence treatments. Soil incorporation did not improve preemergence chemicals for corn but did for soybeans.

SUPPORTED BY Iowa State Government - Des Moines

4.0112, INFLUENCE OF CLIMATE AND SOIL ON ACTIVITY AND PERSISTENCE OF SOIL-APPLIED HERBICIDES

P.C. KEARNEY, Volcani Inst. of Agric. Res., *Beit Dagan, Israel* (0750-08-07)

OBJECTIVE: Gather basic information on the behavior of newer herbicides, applied on different types of soil and subjected to varying and extreme climatic conditions.

APPROACH: The activity and persistence of herbicides will be estimated concurrently by bioassay and by chemical analysis. Will develop rapid and accurate methods of bioassay for each herbicide covering the range of concentrations for the doses commonly used. For each herbicide, curves of activity will be established, in relation to soil composition (especailly clay and organic matter content and cation exchange capacity). Leaching of herbicides will be followed in different soil types, with rates of watering in accordance to irrigation practice and average rainfall. Herbicidal activity and persistence will be evaluated under changing moisture conditions, i.e., in soil alternately wet and dried. The persistence of herbicides, remaining on the soil surface, subjected to different temperature and sunlight conditions, will be studied in comparison to artificial u.v. irradiation.

PROGRESS: Screening for suitable test plants for bioassay of diphenamid was carried out on two soils; ryegrass and oat were found to be the most sensitive. A rapid bioassay (2 days) was developed, based on the differential elongation of radicles and coleoptile of oat seeds, placed on a substrate containing diphenamid in petri dishes. Diphenamid, and the volatile carbamate herbicide butylate, dissipate easily from the soil surface through upward water movement. Stronger bioactivity was observed when the herbicides were sprayed on a coarse soil surface than on a fine-structured surface. Adsorption of diphenamid on soil and its bioactivity in soil were strongly affected by organic matter but appear to be unrelated to clay content. Diphenamid is easily moved out of the upper soil layer, the extent of the removal depending on the amount of water applied and the adsorptive capacity of the soil. The persistence of diphenamid was followed in moist soil and sand. In Newe Ya'ar soil, 2 ppm of diphenamid was still active after 3 months at 20 C. Loss of activity was slower in sand than in soil, and at 20 C than at 30 C.

4.0113, ANNUAL AND PERENNIAL WEED CONTROL IN SORGHUM, WINTER WHEAT AND SUMMER FALLOWED LAND

W.M. PHILLIPS, Fort Hays Br. Agri. Expt. Sta., *Hays, Kansas* 67601 (0710-01-10)

OBJECTIVE: Develop more effective chemical, cultural, mechanical, and combination methods of weed control in winter wheat, sorghum, fallowed land, and in other crops grown in rotation, with emphasis on field bindweed.

APPROACH: Comprehensive field studies are conducted to evaluate herbicides, mechanical methods, and combinations of the two for weed control in the crops of major concern. Greenhouse experiments supplement the field herbicide studies. Detailed bioassay studies in the greenhouse are used to characterize persistence of herbicides in soil.

PROGRESS: Although we have halted research on the use of herbicide-zero tillage for fallow prior to sorghum production until more satisfactory herbicides are developed, we are continuing research on the herbicide-minimum tillage concept of weed control in a wheat-sorghum- summer fallow rotation. In 1969, plots which received an application of atrazine after the 1968 wheat harvest, and were tilled once in the summer of 1968 and once before seeding sorghum, became infested with weed grasses. Nevertheless, these minimum tillage plots yielded substantially more grain than the plots which were tilled conventionally. Combinations of herbicides, applied preemergence, showed considerable promise for controlling both broadleaf and grass weeds in sorghum without causing undue crop injury. Obeservations were continued on previously treated for field bindweed (Convolvulus arvensis L.) control. Picloram and 2,3,6-TBA are for extended periods. Persistence of 2,3,6-TBA has been previously documented, but persistence of picloram was further studied in 1969. Bioassays showed that it can persist for more than 5 years, although there is a gradual disappearance. Preliminary observations indicated the herbicide may move down in the soil profile through deep cracks which develop during periods of drought.

SUPPORTED BY U.S. Dept. of Agriculture

4.0114, MECHANISM OF ACTION AND METABOLIC FATE OF FUNGICIDES

M.R. SIEGEL, Univ. of Kentucky, School of Agriculture, *Lexington, Kentucky* 40506

The mechanism of action of the fungicide folpet and the systemic activity of Benlate will be studied.

Research will be continued on the action of folpet (N-trichloromethylthio-phthalamide) with high molecular weight cellular constituents. Specifically, the investigation will include studies on: a) nature of the reaction of folpet with nucleic acids and nuclear proteins, and b) effect of the toxicant on the enzymes associated with nucleic acid replication.

A detailed study on the systemic activity of Benlate (1- butylcarbamoyl) 2-benzimidazole carbamic acid, methyl ester) will include: a) the mechanism of uptake and transport in higher plants; b) metabolic transformations of the fungicide by higher plants and microorganisms, and c) persistence of Benlate in crop residues and soil.

4.0115, ROW LENGTH, GRADE AND DRAINAGE REQUIREMENTS OF CROPS

H.T. BARR, Louisiana State University, Agricultural Experiment Sta., *Baton Rouge, Louisiana* 70803 (LAB01408)

OBJECTIVE: Determine slope of land in connection with length of row for adequate drainage for various soils and crops grown in Louisiana.

APPROACH: Land will be graded to provide various gradients and lengths of rows. Crops will be planted and amounts of water flow will be measured at ends of fields. Work in cooperation with ARS Soil and Water Conservation Service, Line projects SWC 6-b2 and SWC 6-b1.

PROGRESS: LA-23: Row Length Versus Grade Study, LSU Ben Hur Farm, using 32 plots totaling 88 acres, where 4 grades and 4 row lengths are under study. Six years of data have been analyzed and a prediction equation for runoff is being developed. LA-28: Fate of Applied Pesticide Study, LSU Ben Hur Farm. Three years' data on the disposition of endrin applied to 12 plots have been analyzed with regard to persistence, degradation, volatilization and contamination of runoff. LA-29, LA-30: Drainage Requirements of Crops, LSU Ben Hur Farm. Three years' data from a study of sugarcane yield as affected by 4 water table depths and two flooding treatments are being analyzed. LA-34: Nitrogen- Sulfur Ratios in Sugar Cane, LSU Ben Hur Farm. The effect of various N/S ratios on sucrose production has been studie ' for three years. LA- 35: Irrigation of Sugarcane, LSU Ben Hur Farm. The effect of two irrigation methods on the yield of sugarcane is being studied.

4.0116, CHEMICAL CONTAMINANTS IN SOIL AND WATER RUNOFF IN NEW ENGLAND

E. EPSTEIN, Univ. of Maine, U.S.D.A. Soil & Wa. Cons. Div., *Orono, Maine* 04473 (SWC-024-AOR-3)

4. PESTICIDES

OBJECTIVE: Determine amounts of agricultural chemicals carried in runoff and erosion; determine persistence of agricultural chemicals and leaching losses under intensive cultivation.

APPROACH: Erosion plots at Presque Isle in continuous potatoes and in a 3 year rotation of potatoes, sugarbeets, and peas are treated with the fungicides, herbicides, and insecticides currently recommended by the Maine Agricultural Experiment Station. Runoff and sediment samples are collected and analyzed after each storm. Soil surface samples are obtained before and after each chemical applicaiton. Soil profile samples are collected and analyzed periodically.

PROGRESS: It is important to know the mechanism by which pesticides move from treated agricultural soils. A laboratory experiment was conducted in which Caribou and Marshall silt loams were treated with DDT, methoxychlor and endosulfan. These soils were then fractionated into selected particle size ranges and insecticide in each size range was determined. For both soils, the greatest concentrations were found in the clay fraction and within this fraction the highest concentrations were in the 0.08 to 0.5 Mu size. The lowest concentrations were found in sand fraction.

SUPPORTED BY U.S. Dept. of Agriculture

4.0117, MICROBIOLOGY AND BIOCHEMISTRY OF PESTICIDES IN SOIL

P.C. KEARNEY, U.S. Dept. of Agriculture, Crops Research Division, *Beltsville, Maryland* 20705 (0750-08-02)

OBJECTIVE: Develop methods for controlling the persistence of pesticides in soils by microorganisms. Investigate role of soil organisms and enzymes in degrading various classes of organic pesticides.

APPROACH: Conducts comprehensive studies on the isolation and identification of soil bacteria, fungi and actinomycetes effective in degrading insecticides, herbicides, fungicides and other organic pesticides. Isolates and characterizes enzymes within soil microorganism that initially cleave the pesticide molecule. Studies development of populations of microorganisms effective in degrading pesticides.

PROGRESS: Propanil is metabolized by soil microorganisms to 3,4- dichloroaniline, 3'3',4,4'-tetrachloroazobenzene, propionic acid, and several unknown metabolites. Labeling experiments indicate aniline ring cleavage is slow. 1,3-Bis(3,4-dichlorophenyl)-triazene has been identified as a new major propanil metabolite. The degradation of propanil by soil microorganisms is inhibited by certain methylcarbamate and phosphate pesticides. Specific methylcarbamates act as competitive inhibitors of the acylanilide hydrolyzing enzyme. Addition of some methylcarbamates to propanil in soil significantly reduces the level of TCAB residues formed in soil.

SUPPORTED BY U.S. Dept. of Agriculture

4.0118, MOVEMENT, PERSISTENCE AND INTERACTION OF PESTICIDES IN SOILS

R.G. NASH, U.S. Dept. of Agriculture, Crops Research Division, *Beltsville, Maryland* 20705 (0750-08-01)

OBJECTIVE: Develop methods to study the vertical and lateral movement of all classes of pesticides in soils. Determine the persistence of pesticides in soils when applied individually or in combination.

APPROACH: Conducts comprehensive studies on the lateral and vertical movement in columns and adsorption of pesticides in and on soils. Surveys the persistence and phytotoxic effects produced by single and combined applications of herbicides with insecticides and fungicides by bioassays and chemical methods of analysis.

PROGRESS: Pesticide movement in soils was studied by the soil thin-layer chromatographic method. In general, movement was correlated positively with water flux and soil pH (acidic herbicides), and negatively with field capacity, organic matter and clay contents, and adsorption. A bioassay was developed whereby algae plus agar was sprayed onto a soil plate; triazine and phenylurea herbicides are easily detected at application rates of ca. 1 microgram. Fungicide movement is traced by an analogous technique using soil fungi in the bioassay. The major source of DDT residues in plants arose from vapor movement off of contaminated soil surfaces. Dieldrin, endrin, and hepthachlor residues resulted primarily from root uptake and translocation through stems to leaves and seeds. Soil organic matter negatively affected root uptake and positively affected soil persistence of these insecticides. Several extraction solutions did not remove all insecticide residues from dried plant materials.

SUPPORTED BY U.S. Dept. of Agriculture

4.0119, CHEMISTRY OF PESTICIDES IN SOILS

J.R. PLIMMER, U.S. Dept. of Agriculture, Crops Research Division, *Beltsville, Maryland* 20705 (0750-08-03)

OBJECTIVE: Develop methods of preparing, detecting, and identifying all classes of pesticides and their residues in soils. Investigate and study the chemical reactions that alter pesticides in or on soils.

APPROACH: Conducts comprehensive studies on preparation of volatile derivatives of organic pesticides and accurate detection of minute amounts of these materials using modern techniques in organic and analytical chemistry. Surveys the changes in pesticide molecules caused by oxidation, reduction and photochemical reactions.

PROGRESS: Twelve laboratories reported finding 78 21% of chlorinated hydrocarbon residues added to three soils. Acid forming fertilizers (N, P, and K) decrease arsenic phytotoxicity by influencing Fe and Al availability. Beans (green and lima) are more susceptible to As residues than spinach and cabbage. Fertility level directly influences the toxicity of As residues. Prometryne affords 4,6- bis(isopropylamino)-s-triazine on photolysis in solution or as a solid. DDE irradiated by wavelengths above 2600A in methanol with oxygen gives 3,6-dichlorofluorenone. Photooxidation of DDT or DDE in methanol gives many products. Of these, 32 were identified by combined mass spectrometry/gas chromatography. Reaction pathways have been proposed. Benzophenone sensitized photolysis of 3,4-dichloroaniline gives 3,3',4,4'-tetrachloroazobenzene and other products. Propanil is decomposed in soil to give a number of condensation products and simple dichloroaniline derivatives including 3,4-dichloroformylanilide. 3,3,4'-Trichloroazobenzene is formed in soil from 3,4-dichloroaniline and 3-chloroaniline in addition to 3,3'-dichloroazobenzene and 3,3',4,4'-tetrachloroazobenzene. Ultraviolet irradiation may reduce or destroy the biological activity of herbicides. Amiben is protected fro the action of light by N-benzoylation.

SUPPORTED BY U.S. Dept. of Agriculture

4.0120, BEHAVIOR OF PESTICIDES AND POLLUTANTS IN SOIL, WATER, AND PLANTS

A.W. TAYLOR, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Beltsville, Maryland* 20705 (SWCW8-AB-7)

OBJECTIVE: Study factors affecting accumulation, movement, and persistence of pesticides and pollutants in soil and water and their uptake by plants.

APPROACH: Laboratory, greenhouse, and field experiments will be conducted on the chemistry and microbiology of chlorinated hydrocarbon insecticides, selected herbicides, and the heavy-metal pollutants in soils and water. Analytical methods will be developed for determining these compounds in soil, water, and plants. Greenhouse and field experiments will be conducted to evaluate the accumulation, movement, and persistence of selected chlorinated hydrocarbon insecticides and certain metal pollutants in soils and water and the accumulation of thess compounds in the plants.

PROGRESS: Three years' measurement of dieldrin concentrations in storm-runoff water from small agricultural watersheds show concentrations decrease steadily to about 30% of their initial values by the third year. No dieldrin was found in a stream draining the general area that contains the treated plots. Field studies on aerial movement of dieldrin indicate that volatilization is the main pathway by which dieldrin leaves the soil. Compounds derived from alfalfa distillates accelerated the anaerobic decomposition of DDT in soil. Studies show the adsorption of amitrole and prometone on montmorillonite and soil organic matter is dependent on the surface proton supply. Bromegrass takes up Cd

more readily than Pb, or Zn. Plant uptake of Pb increases very slowly with increasing Pb content of the soil, but is sensitive to pH changes. Studies on phosphate and nitrate losses in water draining woodlnad and agricultural areas have been initiated. Preliminary data show small but measurable amounts from both sources.

SUPPORTED BY U.S. Dept. of Agriculture

4.0121, CONTROL OF PESTICIDES IN SOIL AND WATER
A.W. TAYLOR, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Beltsville, Maryland* 20705 (SWC-024-AB-3)

OBJECTIVE: Study factors affecting accumulation, movement and persistence of pesticides in soil and water and their accumulation by plants.

APPROACH: Laboratory greenhouse and field experiments are conducted on the chemistry and microbiology of chlorinated hydrocarbon insecticides and selected herbicides. Greenhouse and field experiments will be conducted to evaluate the accumulation, movement and persistence of selected chlorinated hydrocarbon insecticides in soil, air and water and their accumulation in plants. Laboratory experiments will be conducted on the chemistry of pesticides and herbicides in soil and water. Analytical procedures for the determination of these compounds will be developed where necessary.

PROGRESS: Field studies demonstrated that volatilization is the principal pathway by which dieldrin and heptachlor are lost from soil to the general environment. The concentrations of the insecticides in corn leaves exposed to the vapors are in the order of 1 ppm, while the concentrations in the kernels remains less than 0.02 ppm. The total amount of pesticide in the plant is about 1 gram per acre. Dieldrin remains stable on the leaves, but most of the heptachlor is degraded to heptachlor epoxide. Laboratory studies have confirmed the existence of natural compounds in green plant tissues that may be mistaken for dieldrin in routine chemical analyses. Procedures for overcoming the analytical difficulties when these compounds are present have been developed. Research on analytical methodology needed for the identification and determination of pesticides in the environment is continuing.

SUPPORTED BY U.S. Dept. of Agriculture

4.0122, NEUTRALIZATION REACTIONS IN ACID SOIL AND CLAY SYSTEMS AND THEIR EFFECT ON PLANT GROWTH
J.H. BAKER, Univ. of Massachusetts, Agricultural Experiment Sta., *Amherst, Massachusetts* 01002 (MAS00219)

OBJECTIVE: Study the influence of chemical properites of acid soil and clay systems on the rate of reaction of liming materials, the effect of application of liming materials on the chemical composition of plants.

APPROACH: Acid soil and clay systems will be treated with liming materials and the progress of the reaction studied by measuring changes in exchangeable aluminum and pH and diffusion of Ca-45 into the system from $CaCO_3$ particles. The chemical composition of the soil solution and plants grown in acid soil and clay systems will also be measured as a function of time after application of liming materials.

PROGRESS: Preliminary studies using ion exchange resins and a calcium sensitive electrode indicate that about 20% of the calcium in soil solutions extracted from field moist soils by pressure ultrafiltration or by displacement with salt solution is in some form other than simple calcium ions, perhaps an organic complex. Presence of complex forms of calcium in the soil solution would be expected to influence calcium availability to plants, movement of calcium in soils and the apparent solubility in soil moisture of such calcium compounds as carbonates and phosphates. Studies of atrazine sorption and desorption from acid and limed soils indicate that atrazine sorption is not completely reversible and that increasing soil pH although decreasing atrazine adsorption does not increase the reversibility of the reaction.

SUPPORTED BY U.S. Dept. of Agriculture

4.0123, PERSISTENCE, ACCUMULATION AND FATE OF PESTICIDES IN CRANBERRY SOILS AND RESERVOIRS
K.H. DEUBERT, Univ. of Massachusetts, Agricultural Experiment Sta., *Amherst, Massachusetts* 01002 (MAS00251)

OBJECTIVE: Study of pesticides in relation to accumulation and persistence, movement to water, final destination and concentration of pesticide chemicals used on cranberry bogs.

APPROACH: Investigations on the chlorinated hydrocarbons, similar studies on organic phosphates. Soil samples at varying depths taken in cranberry bogs, ditches and reservoirs. Perennial vegetation, algae and water animals will be collected and analyzed.

PROGRESS: Work on this project had been interrupted for several months in consequence of personnel changes. The distribution of dieldrin and DDT (detected as p,p -DDT) in soil was closely studied using both gas-liquid-chromatography and thin-layer chromatography. Approximately 75% of dieldrin residues and 85-90% of DDT residues in the 1-4 inch layer of soil are present in the top two inches. Leaching experiments showed that over 0.4% of dieldrin residues in soil (containing 2.3 ppm of dieldrin) can be removed with water corresponding to 10 inches percolated through two inches of soil. Dieldrin and DDT residues in drainage ditches and canals were generally higher (0.4-0.7 ppm) than in 1965 (0.092 ppm). The field experiment with parathion reported last year was repeated. Amounts of residues detected in drainage water were slightly lower than the amounts detected the year before.

SUPPORTED BY U.S. Dept. of Agriculture

4.0124, TRANSLOCATION OF PESTICIDES FROM CRANBERRY BOGS TO THEIR SURROUNDINGS
K.H. DEUBERT, Univ. of Massachusetts, Agricultural Experiment Sta., *Amherst, Massachusetts* 01002 (MAS00293)

OBJECTIVE: Determine translocation of pesticides from cranberry bogs and relationship of organic matter.

APPROACH: Actual bog conditions will be studied and simulated in the laboratory. Interaction of pesticides and organic colloids will be determined. Determinations will be made of cation exchange capacity, pesticide residues, exchangeable bases and carbon content of soil.

PROGRESS: Monitoring studies on dieldrin and DDT in bog soil and drainage canals were continued. Most important result: ratio of translocation of DDT on a cranberry bog--2 ppm about 120 feet in 12 years. Correlection between pesticide residues and cation-exchange capacity, total exchangeable bases, exchangeable Ca , K , Na and base saturation are caused by the correlation between amounts of pesticide residues and organic matter in the soil. Pesticide residues (dieldrin and DDT) in flood water were about 10% above the residue levels in fresh water used for flooding. Copper of copper sulfate applied at a rate of 4 lbs./acre/foot water disappears from flood water from about 0.6 ppm Cu (double dosage) to 0.02 ppm Cu and less within 10 days.

SUPPORTED BY U.S. Dept. of Agriculture

4.0125, INSECTS INFESTING FIELD AND TRUCK CROPS
G.E. GUYER, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00194)

OBJECTIVE: Evaluate the biology, economics and possible avenues of control of major insect populations of vegetable and field crops.

APPROACH: Special attention is directed toward the emerging resistant population of soil maggots infesting onions and cruciferous crops; the developing of the emerging soil insect control problem resulting from the elimination of hydrocarbon materials from control schedules. Special attention is directed to the wireworm and grub problem on potatoes; concentrated effort is being devoted to the improvement of the systemic insecticidal control technique to reducing numbers of sprays and to provide a more economic control program with a minimum of hazards; cooperative studies have been initiated with the processing indus-

try to follow the concentrated residue problem resulting from residue buildup in our major organic soil areas. Ways of living within the register-tolerance problem are being formulated; the magnitude and implications of insecticidal drift resulting from application as well as soil contamination.

PROGRESS: Organophosphate insecticides still provide excellent control of the onion maggot. Field research has evaluated numerous compounds and formulations. Seed corn maggot activity indicates a potential problem to vegetable and field crops. Preliminary work on granular treatments may lead to alternate control techniques for this insect. The cabbage maggot caused total loss to unprotected rutabaga plantings; however new materials when labeled through assistance of pesticide research center will provide excellent control. Twenty-three experimental and commercial formulations of insecticides were evaluated for the insect complex on potatoes, celery, cabbage, peppers, snap beans and muskmelons. Many of these show promise and will be further studied. Seventeen granular or low volume applications of soil insecticides were evaluated on nematodes and foliar insects on potatoes and beans. Only light infestations of insects developed but nematode control was observed. The role of nematode control in cash crop rotations was further studied. Increased yield was obtained after applications of fumigants and granular nematocides. This project will continue since grower interest is high. The European corn borer caused extensive damage to many crops, especially snap beans, peppers and potatoes so emphasis will be placed on this insect in 1970.

SUPPORTED BY Michigan State Government

4.0126, RELATIONSHIP OF PESTICIDES IN SOIL, WATER AND PLANTS

G.E. GUYER, Michigan State University, Graduate School, *East Lansing, Michigan* 48823

The movement, degradation, and concentration of pesticides in the soil ecosystem was investigated. Special attention was directed to the sorption phenomenon as it relates to clay minerals and organic matter. Selected pesticides were followed through the various trophic levels of the soil ecosystem for the purpose of evaluating possible avenues of pesticide concentration as well as degradation.

Comparable investigations were associated with the movement, concentration and elimination of pesticides in the aquatic environment. The physiological and morphological effects of pesticides on selected aquatic vertebrate and invertebrate organisms was determined. Special attention was directed to the evaluation of the pollution related stress effects on electrophysiology of selected nerves.

Research was also associated with the absorption and metabolism of biologically active chemicals by leaf and fruit tissue. Herbicides were investigated to determine their effect on plant composition. The research with the effects of herbicides on plant composition has provided a practical means whereby the protein content of the edible portions of plants may be increased in developing countries.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.0127, REDUCTION OF HAZARDS ASSOCIATED WITH THE PRESENCE OF RESIDUES OF INSECTICIDAL CHEMICALS IN THE ENVIRONMENT

M.M. MORTLAND, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00927)

OBJECTIVE: Determine the fundamental physical, biochemical, and biological factors influencing occurrence, magnitude, interaction, and persistence of insecticidal chemical residues in soils and raw agricultural commodities.

APPROACH: Adsorption of insecticidal chemicals by clay minerals will be studied using techniques of infrared absorption, x-ray diffraction and chemical techniques to determine mechanisms of bonding. Stability of the resulting complexes will be evaluated in dry and wet environments. The effect of exchangeable cation on the complexes formed will be investigated. Where appropriate, bioassays of the colloid- insecticides complexes will be made to determine the activity of the chemicals in the adsorbed state.

PROGRESS: Alfalfa residues added to soil accumulated pentachloronitrobenzene (PCNB) to levels 6- to 10-fold higher than the concentration in soil. At incubation periods from one to 32 days, colonization of the alfalfa residues by fungi was greater in soil free of PCNB than in soil containing PCNB. Of specific fungi enumerated, *Pythium* and *Fusarium* spp. increased in the presence of PCNB in soil, whereas *Rhizopus stolonifer* and *Penicillium oxalicum* decreased. These changes were correlated with the sensitivity of these four fungi to PCNB. The proportion of fungi insensitive to PCNB increased in alfalfa particles incubated in soil containing PCNB, as compared with those in soil without PCNB. Dieldrin was also concentrated several fold by alfalfa particles in soil. The kind of exchangeable cation on clay is of major importance in determining the energy of adsorption of pesticides to clays. They maybe bound to exchangeable metal cations by coordination or to organic cations by hydrogen bonding. Infrared absorption showed dialkylamides interact with organic cations on clay through hydrogen bonding. Proton transfer reactions involving pesticides at clay surfaces were observed. Binding of aromatic molecules to clays having Cu(II) as the exchangeable cation was found to involve pi elections of the organic material. Bioassay studies on pesticide-clay complexes showed bioactivity depended upon the kind of exchangeable cation on the clay with which the pesticide was complexed.

SUPPORTED BY U.S. Dept. of Agriculture

4.0128, CHEMICAL AND PHYSICAL PROPERTIES OF ORGANIC MATTER OF MICHIGAN SOILS

A.R. WOLCOTT, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00636)

OBJECTIVE: Establish the range of organic C, N, P and S in major soil series and management groups. Characterize the organic matter in representative soils in terms of proximate composition, cation exchange capacity and functional group analysis.

APPROACH: Analysis of soil samples form soil survey activities, field research plots and a significant porportion of farm samples passing through the central soil testing laboratory. Objective 2 will involve detailed studies with a very few soils selected to permit correlation with soil genetic factors.

PROGRESS: Useful adsorption isotherms were obtained when low concentrations approaching true solutions of DDT were used (1 ppb). Calculated distribution coefficients were used to compare plant and microbial tissues with different soils and derived soil fractions. Sorptive capacity of residual soil materials for DDT increased as biologically active fractions extractable with hot water or dilute acid were removed. In the course of these studies, procedures and rationale have been developed for projected investigation of pesticide partitioning among ecologically significant components of soil organic matter.

SUPPORTED BY Michigan State Government

4.0129, ENVIRONMENTAL IMPLICATIONS OF PESTICIDE USAGE

R.S. ADAMS, Univ. of Minnesota, Agricultural Experiment Sta., *Saint Paul, Minnesota* 55101 (MIN-25-074)

OBJECTIVE: Special emphasis will be on organophosphate insecticides and triazine herbicides. Devise and improve sampling, extraction and analytical techniques to facilitate quantitation of these pesticide residues and degradation products in soil, plants and animals. Conduct a regional study of the interaction of these pesticides employed for control of corn pests. Evaluate the influence of regional soil and meteorological factors on the persistence, biological activity and soil movement of these chemicals, singly or in combination and in the presence of other environmental inputs. Examine the action, persistence, degradation and translocation of selected biocides and their metabolites in plants, animals and microorganisms. Describe and evaluate biocide cycling through the soil and water environments particularly in reference to food chains.

APPROACH: Preliminary work will be in laboratoby or greenhouse to ascertain best analytical procedures, soil persistence and mobility of pesticide in soil, adsorptivity of pesticide to soil, interactions between soil factors and pesticides and influences of soil factors in pesticide activity. Field trials will be

established with selection based upon pertinent variables. Each station will cooperate procedures for examining some phase including: effects on crops or succeeding crops, efficiency of pest control, leaching of pesticides effects on soil animals and microbes, interaction effects, influence of weather variability and persistence of the pesticide in soil.

PROGRESS: Bioassays of DDT were completed in 31 soil samples. Because the bioassay procedure had to be modified, the samples had to be divided into two groups for statistical analysis. The group with the aberrant samples included all samples containing interstratified minerals and large amounts of amorphous Fe and Al. Organic matter exerted the greatest influence on the bioactivity of DDT in both groups. The adsorption of lindane from aqueous solution by these same soils (32 samples) was also examined. A regression equation including only organic carbon explained 89% of the variability. Adsorption of lindane from solution varied from 4 to 90%. The absorption of lindane was related to the bioactivity of DDT in the same soils at the 1% level. Lindane adsorption was readily reversible.

SUPPORTED BY U.S. Dept. of Agriculture

4.0130, RESEARCH IN WEED SCIENCE AND WEED CONTROL

R. BEHRENS, Univ. of Minnesota, Agricultural Experiment Sta., *Saint Paul, Minnesota* 55101 (MIN-13-037)

OBJECTIVE: Develop new principles and practices for the control of weeds in agronomic crops. Determine the effectiveness of cultural and chemical methods of weed control. Evaluate the toxicity of new herbicides to weeds and crop plants. Determine the safest, most effective means of applying herbicides to agronomic crops and weeds. Determine the persistence of herbicides in crops and soils. Study factors involved in herbicidal selectivity. Investigate physiological responses of plants to herbicides. Determine the mode of action of herbicides.

APPROACH: Evaluation of new chemicals with proven herbicidal activity will be made in laboratory, greenhouse and the field to determine their possible value for agricultural use by applying these chemicals to agronomic plants and weeds under controlled conditions. The influence of environmental (temperature, light, moisture) factors on herbicidal activity will be studied in growth chambers. Bioassay, radioisotopic techniques, gas, paper and thin layer chromatography, ultra-violet and infra-red spectrophotometry will be used to study the mode of action of herbicides, physiological responses of plants to herbicides and the dissipation of herbicides in plants or soils.

PROGRESS: The long-term persistence of picloram in Minnesota soils was apparent from injury to soybeans seeded in 1969 on plots treated with 2 to 3 lb/A of picloram in 1966. The picloram residue was greatest in areas where soil organic matter was lowest. Repeated annual applications of atrazine, 3 lb/A, for 4 years (1965-1968) did not result in an accumulation of atrazine great enough to seriously reduce yields of flax and soybeans in 1969 though stands of these crops were thinned. Two s-triazine herbicides, SD-15418 and S-6115, show promise for weed control in corn and cause less residual phototoxicity in soil than atrazine. Soil incorporated preemergence applications of alachlor were much more effective for the control of yellow nutsedge than were surface applications when rainfall was low. The tolerance of alfalfa and red clover to 2,4-DB does not arise from a failure of these species to convert 2,4-DB to 2,4-D by the beta-oxidation pathway as has been reported by others.

SUPPORTED BY U.S. Dept. of Agriculture

4.0131, INSECTS ATTACKING WOOD AND WOOD PRODUCTS IN STORAGE AND IN USE

H.R. JOHNSTON, U.S. Dept. of Agriculture, Southern Forest Expt. Station, *Gulfport, Mississippi* 39501 (SO2201)

OBJECTIVE: Develop information on important wood products insects life histories, behavior, nutritional requirements, attractants, regulating mechanisms - use this information to work out methods for their prevention and control.

APPROACH: Study nutritional requirements of Lyctus and Anobiid powder-post beetles, investigate means for depleting wood of required nutrients, study life history and effects of environment on important species of drywood termites, test soil insecticides for preventing attack of subterranean termites; investigate laboratory techniques for determining field effectiveness of soil insecticides.

PROGRESS: Field studies still in progress in sandy loam soil in south Mississippi show 100% protection against native termites with 1% chlordane for 21 years, 0.5% aldrin or 0.5% dieldrin for 20 years, and 0.5% heptachlor for 17 years. The chemicals were applied as water emulsions at the rate of 1 pint per square foot. These formulations are still effective after 10 years in heavy clay soil of the Mississippi Delta and in limestone soil at State College, Mississippi. (No other chemicals are known that will give long-term effectiveness against subterranean termites.) Recent analyses for chemical residues and bioassays of over 300 soil samples taken adjacent to field treatments of chlordane applied in 1948, aldrin and dieldrin applied in 1949, and heptachlor applied in 1952 show that the chemicals have moved only a few inches horizontally and vertically from where they were applied. Five years of monitoring for chlorinated hydrocarbons from a spring and a bog area downgrade from large termite control study plots established in 1956 and 1958 have revealed no detectable quantities of the insecticides. Several carbamate and phosphate compounds were applied in field studies in 1967 to determine their effectiveness against subterranean termites. After 3 years most of these compounds are ineffective.

SUPPORTED BY U.S. Dept. of Agriculture

4.0132, REDUCTION OR ELIMINATION OF ADVERSE EFFECTS OF PESTICIDE RESIDUES ON FOOD AND FEED PRODUCTS

B.F. BARRENTINE, Mississippi St. University, Agricultural Experiment Sta., *State College, Mississippi* 39762 (MIS-3-206-0766)

OBJECTIVE: Study food and feed products with respect to the location and persistence of pesticide residues in market products, and the development of commercial marketing and processing techniques for the detection, removal and/or neutralization of pesticide residue effects.

APPROACH: Samples of soybeans from commercial storage will be selected. Effects on residue reduction by cleaning and washing will be investigated. The location and persistence of endrin residues in soybeans and soybean products produced on endrin contaminated soil will be studied.

PROGRESS: The uptake of pesticides from contaminated soils by the soybean plant has been verified by both field and plot work. The principle pesticides found in soybean oil are DDT, toxaphene, and endrin. Toxaphene and DDT present no problem, as the amounts found are usually well below the tolerance level. The problem with endrin is more critical, since there is no tolerance for this pesticide. It has been reported that the deodorization step in the commercial refining of oils removes much, if not all, of the pesticides in crude oils. A working arrangement was made with a commercial refining plant to study the effect of refining on the pesticides in the crude oil. It has been verified that the deodorization step of refining does remove essentially all of the DDT, toxaphene, and endrin. Much of the pesticides are found in the 'distillate,' a volatile oily fraction which is recovered by the refining industry. It appears very difficult, if not impossible, to relate the amount of pesticides in the distillate to the total quantity of pesticides that was in the crude oil.

SUPPORTED BY U.S. Dept. of Agriculture

4.0133, DETERMINATION OF HERBICIDAL RESIDUES IN PLANTS AND SOILS, AND FATE OF HERBICIDES IN CERTAIN SOILS

A.W. COLE, Mississippi St. University, Agricultural Experiment Sta., *State College, Mississippi* 39762 (MIS-3-206-1454)

OBJECTIVE: Follow residue patterns of herbicides in soils, and in plants grown in succession and in rotation by employing satisfactory methods. Determine the fate of herbicides in certain soils by following the steps involved in degradation.

APPROACH: The investigations will be conducted under field, laboratory and controlled environmental conditions. The field work will employ certain vegetable crops, woody ornamentals and turf species. Establish the pattern of herbicide dissipation

in the soil under diverse conditions, field plots will be established and treated with certain herbicides. The herbicides will be applied at recommended rates and rates in excess of those currently in use.

PROGRESS: Micro-organisms were isolated from soil taken at prime locations in previously treated plots using Acid PDA and Rose Bengal media at inoculation temperatures of 5, 10, 15, 20, 25, 30, 35, and 40 C. Cultures isolated did not vary significantly with location. Cultures were then exposed to herbicides which have had long periods of successful use or are currently being used in large acreage situations in Mississippi. Several of the fungi were found to be inhibited by these chemicals in their growth while some appeared to be stimulated. Using standardized inoculation techniques for liquid growth medium and known concentrations of herbicides, one fungus which is inhibited in plate culture was found to be modified physiologically (at least temporarily) by the herbicide. The degree of modification is consistent with concentration of herbicide. In addition to being modified, the organism also gains the ability to degrade the herbicide present in solution. Measurement of dry weight after a known period of exposure and color variation have shown that these changes occur at concentrations which could be present in soil from normal usage. Field plots for continuous application of the herbicides have been established to determine if this modification is consistent.

SUPPORTED BY U.S. Dept. of Agriculture

4.0134, INACTIVATION AND LOSS OF PESTICIDES FROM SOIL

B.J. STOJANOVIC, Mississippi St. University, Agricultural Experiment Sta., *State College, Mississippi* 39762 (MIS-3-207-0569)

OBJECTIVE: Determine inactivation and loss of pesticides from soil by volatilization, and microbiological and non-microbiological degradation.

APPROACH: Soils representing important land resource areas in the South and pesticides of hazardous and economic importance will be used. The extent and importance of volatilization of pesticides from soils will be determined under controlled laboratory conditions. Products of microbially degraded pesticides and microorganisms responsible for degradation will be identified. Chemical changes in pesticides will be determined in soils void of microorganisms under varying pH, temperature, moisture and mineralogical composition of soils.

PROGRESS: Biodegradeability and persistance of DDT, dieldrin, and malathion was studied in West Point loam, Angie sandy loam and Houston clay. Each insecticide was added at concentrations of 2, 4, 8, and 16 ppm to soil samples alone or to soil samples containing 150 ppm urea-N. Following incubation (56 days) soils were analyzed for insecticide content, microbial numbers, and mineral nitrogen. Malathion dissipation was also studied in sterile and non-sterile soils and aqueous soil dilutions. In these investigations DDT and dieldrin remained essentially unchanged throughout 2-month incubation, regardless of the concentration at which they were applied, the soil type employed, and whether or not nitrogen was applied as urea. DDT-amended Houston clay, however, showed appreciable accumulation of p,p'-DDE. This accumulation was directly related to the rate at which DDT was added and it was substantially greater in samples which contained urea-N than in those without urea. In non-sterile West Point loam and Houston clay malathion was not detectable after 24 and 48 hours incubation. In non-sterile Angie sandy loam there remained approximately 4% of added malathion after 10 days incubation. Non-sterile and sterile aqueous dilutions showed similar patterns of diminishing returns of malathion upon incubation. It is concluded from the data that malathion is degraded chiefly if not solely by soil microorganisms.

SUPPORTED BY U.S. Dept. of Agriculture

4.0135, EFFECT OF PESTICIDE USAGE ON SOIL MICROFLORA IN AGRONOMIC AND HORTICULTURAL CROPS

D.K. BAGGA, Delta Branch Experiment Sta., *Stoneville, Mississippi* 38776 (MIS-SUW-0107)

OBJECTIVE: Investigate the qualitative and quantitative changes brought about in soil microflora by application of pesticides and evaluate the usage of a certain pesticide for a certain crop with regard to microbial populations.

APPROACH: Field soils treated with various pesticides and pesticide combinations for different lengths of time will be used to assay their microflora. Pure cultures of soil microorganisms will be used to study the effect of pesticides in vitro.

PROGRESS: Microorganisms from the soils of Delta of Mississippi were isolated and their frequency determined. Effect of trifluralin on the growth of various soil fungi varied. Trifluralin at 1 ppm incorporated in potato-dextrose agar inhibited the growth of Aspergillus niger. All other fungi tested were not affected by this concentration of the herbicide added. Higher concentrations (1000 ppm) of fluometuron and diuron added to liquid culture medium had an adverse effect on growth of Glomerella gossypii, Pythium deliaryanum, Rhizoctonia solani, and Verticillium alboatrum. Diuron at concentration of 1 to 10 ppm stimulated the growth of soil borne pathogens: P. deliaryanum and R. solani. Addition of diuron, fluometuron, norea, planavin, and trifluralin to soil seemed to increase its microbial population. An interaction between chloroxuron and seedling disease organism R. solani was discovered. Chloroxuron at 3 ppm in unsterilized soil or in the presence of R. solani caused injury to the southern peas, however in sterilized soil there was no apparent injury to the test plants.

SUPPORTED BY Mississippi State Government

4.0136, PERSISTENCE AND DETOXIFICATION OF HERBICIDES IN SOIL

K.E. SAVAGE, Delta Branch Experiment Sta., *Stoneville, Mississippi* 38776 (MIS-SUW-0102)

OBJECTIVE: Investigate herbicide persistence as affected by herbicide combinations, rates, application methods, climatic and cultural conditions.

APPROACH: The persistence of selected herbicides will be studied as related to climatic, edaphic, and cultural conditions. Due to the time involved in persistence research, only those herbicides which are in commercial use will be considered. The studies will consist of field, greenhouse and laboratory studies as well as appropriate analysis of soil samples from field research plots and commercial fields.

PROGRESS: Nitralin and trifluralin persistence was studied as a function of soil and environmental factors in the field, greenhouse, and laboratory. Preliminary results indicate no significant accumulation of either herbicide under field conditions. Soil pH was negatively associated with persistence of both herbicides. Nitralin persisted longer under anaerobic than under aerobic soil conditions.

SUPPORTED BY Mississippi State Government

4.0137, PERSISTENCE OF HERBICIDES IN SOILS

K.E. SAVAGE, U.S. Dept. of Agriculture, Southern Weed Science Lab., *Stoneville, Mississippi* 38776 (0710-01-14)

OBJECTIVE: Determine the persistence of herbicides used in the Southeastern United States in relation to soil properties.

APPROACH: Study the influence of chemical and physical properties of agricultural soils of the Southeast in relation to persistence of specific herbicides and to interaction with other pesticides in the soil. Evaluate and quantitate the movement, transport, and loss of herbicides in and from soils. Investigate methods to decrease or to extend the residual lifetime of herbicides in selected soils of the region.

PROGRESS: Postemergence applications of certain petroleum naphthas effective and economically control many species of weeds in cotton under ideal conditions. Lack of crop tolerance, however, prevents safe use after cracks appear in the bark at the base of cotton stems. Data from 4 years of research indicate that water emulsions of certain aromatic petroleum fractions provide more effective control of the target weeds than unemulsified naphthas and that the cotton remains tolerant at stages of growth that would be injured by unemulsified naphthas. Results of a survey on persistence of nitralin and trifluralin in soils of the Mississippi Delta indicated no significant accumulation of these herbicides in cotton or soybean fields. Nitralin residue was negatively

correlated with soil pH. Trifluralin persistence was negatively correlated with organic matter, soil pH and cation exchange capacity. Greenhouse bioassays indicated that both nitralin and trifluralin persisted longer under acid soil conditions than under neutral or slightly alkaline conditions.

SUPPORTED BY U.S. Dept. of Agriculture

4.0138, EQUIPMENT AND TECHNIQUES FOR CHEMICAL CONTROL OF WEEDS IN CORN AND SOYBEANS
M.R. GEBHARDT, Univ. of Missouri, U.S.D.A. Agric. Eng. Res. Div., *Columbia, Missouri* 65201 (209-056-A112-B)

OBJECTIVE. Improve methods of evaluating weed control practices for field crops and establish criteria for design and use of improved cultivation and herbicide application equipment.

APPROACH. Evaluate effects of herbicide application and cultivation on weed control, crop yields, retention of chemical residues in the soil and contamination of nontarget areas. Develop procedures to objectively measure efficiency of application of herbicidal chemical in sprays, granules, foam and other forms. Determine requirements for mixing of pre-emergence herbicides in the soil, and the influence of various methods of soil mixing on effectiveness of the herbicide treatments. Determine factors affecting design requirements criteria for utilization of cultivation equipment for weed control, for use alone or in conjunction with herbicides.

PROGRESS. Soybean stands were reduced when 1/2 lb/A of trifluralin was incorporated with the disk harrow. Poor weed control was obtained when trifluralin and nitralin were applied at 0.5 and 1.0 lb/A and incorporated with the disk harrow. Incorporation with a powered rotary cultivator resulted in excellent weed control with the same herbicides. Incorporation with a mulch treader resulted in no soybean damage and excellent weed control. A comparison of low volume applications of several preemergence herbicides for weed control in corn showed that the herbicides are as effective at 1 gpa as at 5 or 20 gpa when applied with low volume fan-type spray nozzles. Preemergence herbicides for corn and soybeans showed improved weed control when followed by rotary hoeing at spike stage. Field and laboratory studies of the persistence of trifluralin in the soil when surface applied and when incorporated with a powered rotary cultivator, mulch treader, and disk harrow were initiated this year. Preliminary data indicate that there are differences in herbicide persistence due to method of incorporation. Large variations in herbicide concentrations due to environmental interactions with methods of chemical analysis prevented complete analysis this year.

SUPPORTED BY U.S. Dept. of Agriculture

4.0139, THE USE AND FATE OF BIOREGULANTS
B.G. TWEEDY, Univ. of Missouri, Agricultural Experiment Sta., *Columbia, Missouri* 65201 (MO00605)

OBJECTIVE. Interactions of selected plant life and bioregulants, effect of bioregulants upon selected metabolic pathways of microorganisms and vascular plants, biodegradation of pesticides and identify some of the degradation products.

APPROACH. Several different forms of plants will be grown in presence and absence of selected bioregulants under environmentally controlled and natural conditions. Bioregulants to be used in initial studies will include those compounds which are potential nitrogen, carbon or nitrogen and carbon sources for microflora. Pesticides will be incorporated into soil and water and rate of disappearance will be followed by chemical and bioassays. Ecological changes in microflora will be followed. Organisms will be incubated in radiorespirometric flasks which contain selectively labeled metabolic intermediates and the radioactive carbon dioxide evolved will be trapped. Intermediates will include radioactive glucose, pyruvate and acetate labeled in different positions.

PROGRESS. Conidia of Fusarium oxysporum were incubated with thiram and selectively labeled glucose. Thiram at 1, 2 and 4 ppm had little effect, but 8 and 16 ppm were highly inhibitory to the HMP and slightly inhibitory to the EMP pathways. Triazine or substituted urea herbicides used with thiram either reduced or augmented the effect of the fungicide, depending upon the herbicide. Similar effect upon soil microfloral populations were observed when the combinations were applied to soils. Thus, herbicide-fungicide combinations could select the predominant soil microflora. Representatives of the soil microflora showed a wide variation in their ability to degrade herbicides. The fungi degraded 100% of the diphenylether compound but had little effect upon the others. Algae degraded the diphenylether and triazine. Corn seedlings resistant or susceptible to atrazine were incubated with C- ring- or chain-labeled atrazine. None of the ring moiety was accumulated in the mitochondria nor was it incorporated into the nucleic or free amino acids. Cell-free homogenates from the resistant and susceptible lines were found to rapidly hydroxylate atrazine and the reaction was highly dependent upon pH. Thus it is doubtful that the ability to hydroxylate atrazine is the major factor for resistance to this herbicide.

SUPPORTED BY U.S. Dept. of Agriculture

4.0140, THE INTERACTION OF MICROORGANISMS AND PESTICIDES
B.G. TWEEDY, Univ. of Missouri, School of Agriculture, *Columbia, Missouri* 65201

The importance of soil microorganisms in the degradation of representative compounds from the major classes of herbicides with special interest in those containing carbon nitrogen bonds is being investigated. The identification of the degradation products will be attempted with a GC-Mass Spectrometer. The pathways by which the compounds are degraded will be studied when the pursuance of these mechanisms are thought to be feasible. Studies will also be included to determine the effect of herbicides and their degradation products on the populations, metabolism and other properties of soil microflora and seedling plants. The induction of microorganisms to rapidly degrade representative commercial herbicides is being investigated. Combinations of fungicides and herbicides are being applied to soils incubated under field and laboratory conditions to determine the effect of fungicides on microbial degradation of herbicides.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.P.P.

4.0141, SORPTION AND DESORPTION OF CHLORINATED HYDROCARBON PESTICIDES IN AQUATIC SEDIMENT MINERALS
J.C. HUANG, Univ. of Missouri, School of Engineering, *Rolla, Missouri* 65401

The purpose of this research project is to investigate the sorption and desorption reactions of selected chlorinated hydrocarbon pesticides with clay minerals in laboratory-controlled environmental systems. Particular emphasis will be placed on ascertaining the effect of organic matter on the behavior of sorption and desorption and determining the influence exerted by selected other environmental stresses, including pH, temperature and salt concentration of the water.

Pesticide selected for this study include DDT, dieldrin and heptachlor, and clay minerals selected are kaolinite, montmorillonite and illite. Laboratory investigations will include the following studies: (a) Batch and column studies to evaluate the effect of organic matter on the sorption and desorption reactions, and (b) Aquatic model studies conducted under rigidly controlled conditions to ascertain the effect of other environmental factors on the sorption and desorption reactions.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

4.0142, SYSTEMS OF WEED CONTROL
O.C. BURNSIDE, Univ. of Nebraska, Agricultural Experiment Sta., *Lincoln, Nebraska* 68508 (NEB-12-007)

OBJECTIVE. Determine mechanism of seed dormancy and methods of destroying seed in soil. Develop selection criteria for crop competitiveness to weeds. Study factors influencing herbicide phytotoxicity and dissipation. Develop effective weed control systems.

APPROACH. Information gained from seed dormancy studies will be used in attempts to destroy weed viability in soil. Selection criteria on seedlings will be correlated with crop com-

petitiveness to weeds. The influence of herbicide placement, soil texture, climate, and production practices on herbicide phytotoxicity and fate will be studied. Weed control systems will be developed using combinations of mechanical, cultural, and chemical weed control methods.

PROGRESS: Dissipation of dicamba was greater in Sharpsburg silty clay loam than in Anselmo sandy loam and was faster in the topsoil than in the subsoil. A sprayer-flamer for weed research was produced which provided constant rate spraying, logarithmic-dosage spraying, and flaming. C-amiben methyl ester showed greater adsorption and less leaching than C-amiben. Soil texture differences had a greater influence on herbicide residue carryover than did climatic differences across Nebraska during 1962 to 1968. Leaching of herbicides into the soil profile was an avenue of herbicide dissipation. Rotary hoeing of plains prickly pear cladodes just prior to spraying improved herbicide performance. Downward movement of picloram was greater in sandy loam than in silty clay loam soils. Widely varying weed densities that had been desiccated by freezing did not reduce combine efficiency in harvesting corn, sorghum, or soybeans. Sorghum yields were reduced 4, 12, and 18% by delaying weeding of plots 3, 4, and 5 weeks as compared with 2 weeks after planting and each week thereafter. Weeds that did not emerge until 4 weeks after planting did not reduce sorghum yields. Under most Nebraska conditions, atrazine applied to sorghum at recommended rates will not persist long enough to cause yield losses of winter wheat in a wheat-sorghum-fallow rotation.

SUPPORTED BY U.S. Dept. of Agriculture

4.0143, BIODEGRADATION OF HERBICIDES IN TREATED SOILS FOR ESTABLISHMENT OF RANGE FORAGE PLANTS

J.E. MAYFIELD, Univ. of Nevada, Agricultural Experiment Sta., *Reno, Nevada* 89507 (NEV00439)

OBJECTIVE: Isolate microorganisms from range soils which are capable of detoxifying s-triazine herbicides, determine the effects of soil type, moisture, temperature, and pH on the rate of herbicidal decomposition in the presence of the selected organism, elucidate mechanisms involved in the degradation of the chemical, utilize information acquired to establish desirable grass species in recently treated range soils.

APPROACH: Microorganisms capable of detoxifying s-triazine herbicides will be selected from arid Nevada rangelands. Rapidly multiplying organisms will be selected and propagated for introduction with the desired grass species to be established on treated rangelands. The organism should create an environment free of the herbicide in the immediate vicinity of the seed, thus allowing a desirable grass to be established in a weed-free environment. Various regimes of temperature, pH, moisture and soil type will be studied determine the rate of chemical decomposition in presence of the test organism. Laboratory studies will be conducted to ascertain the mechanisms involved in microbial detoxification of herbicides.

PROGRESS: Fungi were isolated from atrizine-treated range and field soils. Four isolates of Pennicillium, Aspergillus, Hormodendrum and a filamentous yeast were compared with Aspergillus flavus on mineral media containing atrizine. One isolate of Aspergillus sp. and Hormodendrum sp. were superior to A. flavus in their ability to utilize atrizine as a carbon source. Spores of these fungi were dusted onto the surface of intermediate wheat grass and barley and the seeds planted in atrizine-treated soil. There was considerable inhibition of germination in all seeds treated with the spores of these fungi except A. flavus. Studies are underway to determine the nature of this inhibition since it was not apparent that any of the seeds had been parasitized by these fungi.

SUPPORTED BY U.S. Dept. of Agriculture

4.0144, FATE OF HERBICIDES IN PLANTS AND SOILS

R.D. ILNICKI, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00142)

OBJECTIVE: Determine the fate of herbicides in plants and soil. Ascertain the residual effects of simazine, atrazine, and other herbicides in soil. Compare other herbicides of the phenoxyalkylcarboxylic acid group with 2,4-D on wheat, barley and oats.

APPROACH: Experiments will be designed to establish the residual characteristics of economically important herbicides. Test crops will be planted the following season on previously treated sites to determine the amount of herbicide remaining and to establish the sensitivity of crops that might follow these herbicides. Other bioassay techniques will also be used in greenhouse and growth chamber studies.

PROGRESS: Linuron enters plants passively with water uptake; it is first concentrated in roots which later accumulates in shoots; most accumulates as linuron, it is later degraded through a sequence of reactions to urea and aniline; this degradation is a detoxifying mechanism; and some linuron is retained in a 'bound' form to proteins. Metabolic strides with chlorbromuron revealed the following: the herbicide is degraded to nonphytotoxic compounds in corn; no degradation occurs in cucumber; the difference in degradation explains the difference in sensitivity of these two species. Substituted ureas are recognized as photosynthetic inhibitors explaining in part their herbicidal activity. Studies with linuron, fenuron, monuron, diuron, metobromuron, fluometuron, chloroturon, and chlorbromuron indicate that, with the exception of chloroturon and fluometuron, all increased respiration in plant tissues. This was related to the degree of chlorination in the phenyl ring of the urea molecule. Substitution of one atom effected increases over no chlorine substitution and two chlorine atoms more than one substitution.

SUPPORTED BY U.S. Dept. of Agriculture

4.0145, NEMATOCIDES AND POTENTIAL NEMATOCIDAL CHEMICALS RESIDUES IN PLANTS AND DIFFUSION IN SOIL

W.R. JENKINS, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00415)

OBJECTIVE: Screen new materials for nematocidal activity residues in plants following nematocide applications to soil, and effects on quality of food crops. Factors influencing the diffusion of nematocides in soil.

APPROACH: Greenhouse and field trials of nematocides will be made to determine efficacy. Residues of nematocidal chemicals in food crops will be determined. Long-range studies will be made to determine duration of residual materials in soil. Effectiveness of nematocides under varying environmental conditions will be studied.

PROGRESS: As a result of extensive trials with nematocides on peach trees, it is now recommended that all plantings in land containing *Criconemoides* spp. be treated with dibromochloropropane either before or after planting or dichloropropenes or dibromoethane before planting. Laboratory and greenhouse tests have shown ammonia (as ammonium hydroxide) to give as good or better control of Meloidogyne javanica than dibromochloropropane. Rates as low as 0.05% ammonia gave 100% control in sandy and loamy sand soil.

SUPPORTED BY New Jersey State Government - Trenton

4.0146, CHEMICAL RESEARCH ON INSECTICIDES AND THEIR FORMULATIONS

D.J. SUTHERLAND, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00431)

OBJECTIVE: Improve insecticide formulations through study of physical and chemical properties of carriers, solvents and adjuvants used in the preparation of insecticide concentrates and the effect of these on the stability, dispersal and application coverage of toxicants. Investigate factors affecting the accumulation and decomposition of insecticides on fruits, vegetation and in soils. Investigate the penetration and dispersion of insecticides within the insect body through studies of chemical and biological spreading agents.

APPROACH: Formulation of insecticides will be investigated by small-scale manufacturing. Exposure of formulations to controlled conditions with subsequent insecticide analyses. Field conditions to determine effect on insecticide residues. The effect of spreading agents will be studied by isolating and analyzing insect intercellular constituents and determining the effect of spreading agents on such constituents.

PROGRESS: Project 431 during the past year on insecticides and their formulations has dealt mainly with the insecticide

Abate, as a granule, and factors which influence the efficiency of this insecticide and its formulation. Factors investigated have included size of granule, type of granular carrier, and solvent used to impregnate the insecticide onto the carrier. Evaluation of release has employed a laboratory continuous flow method as well as a bioassay method employing mosquito larvae. Research on the above aspect indicates that all factors mentioned above strongly influence the final efficiency of the granular formulation in the field.

SUPPORTED BY U.S. Dept. of Agriculture

4.0147, FATE OF PESTICIDES IN CLAY AND SOIL SYSTEMS

S.J. TOTH, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ000046)

OBJECTIVE: Determine the factors responsible for the retention of pesticides and herbicides by clay mineral and soils. Determine the nature of the mechanisms involved in the adsorption of these organic compounds by clay minerals and soils. Study and attempt to predict the behavior of these organic chemicals in soils of the Great Zonal Groups.

APPROACH: Clay minerals, kaolinite, illite and montmorillonite will be prepared in homoinic forms (H, Ca, Mg, K and Na) and the adsorption of organic chemicals under standard conditions will be determined. At least two members of each of the Great Soil Zonal Groups will be collected and subjected to the same procedure as the pure clay minerals. The role of organic matter in adsorption will also be evaluated.

PROGRESS: A thesis was prepared by G. MacNamara entitled, 'Adsorption of Some Pesticides on Soils, Clay Minerals and Humic Acid,' which details the four-year study of this problem. The most important findings were: adsorption of linuron, malathion and diphenamid was the lowest on kaolinite clays and the highest in humic acid systems; DDT precipitated on clay surfaces in aqueous solution which explains the persistance of this chemical in soils; adsorption of linuron and malathion by clays or soil was not an exchange reaction; adsorption of linuron and malathion was greater in the A than B horizon samples of N.J. soils; malathion adsorption by humic acid seemed to reduce its decomposition; attempts to remove adsorbed linuron by dilute acid or salt solutions was not successful indicating strong fixation and the bonding of linuron by Ca-montmorillonite was due to hydrogen bonding by the carbonyl group to the clay.

SUPPORTED BY New Jersey State Government - Trenton

4.0148, CROP & WEED RESPONSE TO HERBICIDES, & FACTORS AFFECTING HERBICIDAL ACTIVITY & RESIDUAL SOIL TOXICITY

P.P. ANDERSON, New Mexico State University, Agricultural Experiment Sta., *Las Cruces, New Mexico* 88070 (NM000046)

OBJECTIVE: Determine the effectiveness and selectivity of new herbicides and herbicide combinations in New Mexico, and to compare their effectiveness with herbicides now in use. Determine under controlled greenhouse and laboratory conditions, factors such as dosage, leaching, and site of entry that affect the activity of herbicides, and determine under greenhouse and field conditions, the residual soil toxicity of herbicides and the effect of this residue on crop rotations.

APPROACH: In primary screening tests the crops and weeds will include those of primary concern to New Mexico and be limited to ones that will readily germinate under the field conditions involved; greenhouse and laboratory investigations of highly promising herbicides will be continued, and the soil residual toxicity of herbicides and their effect on subsequent crop rotations and weed populations will be determined by field and greenhouse experimentation.

PROGRESS: In New Mexico, spurred anoda (Anoda cristata) and 'ironweed' (Flaveria repanda), two summer annual weeds are to tolerant to normal treatments of trifluralin and nitralin in cotton fields. Spurred anoda is, at present, the more serious of the two weeds, and it is a major problem in August-planted lettuce fields as well as in April- planted cotton. Early postemergence applications of prometryne or fluometuron as a directed spray has resulted in effective control of this weed in cotton, and there are indications that a new herbicide (RH- 315, trade name Kerb) will selectively control it in lettuce fields. In the laboratory, a 30 minute soaking of the seed of spurred anoda in conc. sulfuric acid was found to be needed in order for the seed to readily germinate. Field tests indicate that Eptam, Casaron, Prefar, CP-53619, SanJoz 6706, and Sinbar appear promising for the control of purple nutsedge, but crop selectivity and active soil-residues may prove to be limiting factors.

4.0149, PERSISTENCE AND TOXICITY OF INSECTICIDES IN SOILS FOR CONTROL OF SOIL-INHABITING INSECTS

G.L. MACK, New York State Agric. Sta., *Geneva, New York* 14456 (NYG00579)

OBJECTIVE: Study the persistence of DDT, dieldrin and chlordane in nursery soils. Study the accumulation of DDT in sweet corn soils from repeated applications over a period of ten years. Determine the DDT content of soils. Determine the decomposition products of DDT in soils.

APPROACH: This will be accomplished by performing pesticide analysis, by chemical and bioassay methods, of soils which have been treated. Analysis will be made after repeated applications to determine the accumulation of pesticides as well as decomposition products.

PROGRESS: Dieldrin has been the most effective and efficient insecticide for the control of European chafer and Japanese beetle. Environmental pollution and the appearance of a Dieldrin-resistant strain of European chafer requires the development of substitute pesticides. Five non-Cyclodiene materials tested over a two year period showed Bayer 37289, a chlorinated organophosphate, to be the most promising. Soil residue analysis indicates that 1 lb. of a 20 lb. per acre application remains after 2 years and gives 100% control. A 10 lb. application gives 100% control for one year but not for two years when the soil residue was reduced to 0.2 lbs. per acre. The effective soil residue of Bayer 37289 appears to be between 0.5 and 1.0 parts per million.

4.0150, STUDY BIOLOGY AND CONTROL OF EUROPEAN CHAFER AND SCARABAEID SPECIES IN NURSERY INDUSTRY

H. TASHIRO, New York State Agric. Sta., *Geneva, New York* 14456 (NYG00525)

OBJECTIVE: Study importance and nature of European chafer injury. Develop means of control for home owner, nurserymen and for regulatory type certification treatment programs, determine toxicity of old and new compounds to the grubs, and, determine persistence of insecticides in field-treated soils.

APPROACH: Observations on the habits and life history of the insect. Phenological plant development. Assay of toxic insecticidal residues in field treatments.

PROGRESS: Two years after application of 20 lb. AI/A acre, Bayer 37289 produced 100% mortality and Dyfonate 23% mortality of 1st instar European chafer grub. The former at 2.5-10 lb. produced [illegible]% mortality. Eggs of the European chafer and the Japanese beetle were introduced into insecticide treated loam. Rates (lb./A-acre) required to eliminate 1st instar grubs were: dieldrin - 0.8 and [illegible]2, Bayer 37289 - 1.0 and 0.6, Dyfonate - 0.8 and 0.6 and Diazinon - 1.8 and 1.4 for the European chafer and Japanese beetle, respectively. Insecticide field plots initiated in a lawn in June were surveyed after 4 months. Dieldrin at 0.5 and 3.0 lb. AI/acre controlled 97 and 100% of both European chafer and Japanese beetle grubs. Chlordane at 1, 2, 4, and 8 lb/acre controlled 88, 88, 93 and 100% of the former and 53, 82, 85, and 99% of the latter, respectively. (All above studies were in cooperation with ENT., USDA). Insecticide plots were initiated in cooperation with the Cooperative Extension Association on July 3 for control of the bluegrass billbug, Sphenophorus parvulus (Gyllenhal) (C.) in home lawns. Larval reductions of 90 % were obtained with formulations and rates of AI/1000 ft as follows: Diazinon 2G and 14G at 3 oz., Baygon 5G at 3 oz. and carbaryl 80S at 6.4 oz. Over 10 weeks, carbaryl 80S treated lawn was rated highest in absence of damage and general vigor followed by

Diazinon 14G and 2G, and Baygon 50W and 5G. Chlordane was ineffective. Diazinon showed the highest toxicity to larvae and adults in laboratory evaluations.

4.0151, THE ROLE OF MICROFLORA IN THE PERSISTENCE AND DECOMPOSITION OF PESTICIDE RESIDUES

M. ALEXANDER, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00061)

OBJECTIVE: Identify the intermediates and products formed during the microbial decomposition of pesticides. Investigate the mechanisms of microbial degradation of pesticides.

APPROACH: Herbicide and insecticide degrading microorganisms will be isolated from soil. The ability of these isolates to degrade the pesticide will be examined by use of intact cells and enzyme preparations. Cells or enzymes will also be incubated with suspected or proven intermediates to determine the subsequent fate of the chemicals. The products of the reactions will be identified by paper, thin-layer and gas chromatography, and by IR, UV, NMR and mass spectrometry. Cometabolism as a means of herbicide and insecticide transformation in soil will also be investigated.

PROGRESS: The metabolism of the herbicide 2,3,6-trichlorobenzoic acid (TBA) by a soil microorganism, Brevibacterium sp., was investigated. In the reaction, 1 mole each of O(2), CO(2), chloride and 3,5-dichlorocatechol were produced from each mole of TBA. The catechol was identified chromatographically and by infrared spectroscopy. The data suggest that 2,3,6-trichloro-4-hydroxybenzoate and 2,3,6- trichlorophenol were intermediates in the sequence. The apparent basis for the catechol accumulation and TBA persistence was established. Investigations of the pathway of 2,4-D degradation have continued, and the steps involved in converting the 3,5-dichlorocatechol formed from 2,4-D to the chlorobutenolide and the decomposition of the latter, possibly to chlorosuccinate and then succinate, have been further characterized. Biochemical models for the ether-cleavage reaction in 2,4-D degradation are under study, and discrete steps involved in the enzymatic cleavage of ethers are being defined.

SUPPORTED BY U.S. Dept. of Agriculture

4.0152, FACTORS INFLUENCING HERBICIDE EFFECTIVENESS

R.D. SWEET, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00758)

OBJECTIVE: Determine the influence of soil moisture, clay content, organic matter and temperature on herbicide performance and crop tolerance.

APPROACH: Work will be concentrated on the thiocarbamates because of their potential utility in vegetable crops and because of their extreme variability in the field. Research will be conducted in the laboratory and the field. Clay and organic matter will be studied on both mineral and muck soils as well as in artifical media involving clays, vermiculite, sand, peat, etc.

PROGRESS: Synergism studies yielded gratifying results. Combinations of Atrazine with either alachlor, Daxtron, Diphenamid, nitralin, or 2,4-D in the presence of non-phytotoxic oil gave plant responses 10 to 20 times that expected when applied post-emergence. Corn, however, was not damaged. Dalapon did not give synergism. Several combinations were made in which no atrazine was included. Promising results were obtained with diphenamid plus trifluralin. Synergism also occurred with trifluralin plus linuron. Unfortunately, however, linuron often caused damage to corn. In these studies total quantities of both toxicants in the successful combinations varied from 4 to 8 ounces per acre, or about 1/10 the normal dosages presently used. When developed into practical recommendations this should provide a significant boost to safeguards against any possible soil pollution from herbicides.

SUPPORTED BY New York State Government - Albany

4.0153, INTERACTION OF HERBICIDES AND SOIL MICROORGANISMS

D.C. TORGESON, B. Thompson Inst. Plant Res., *Yonkers, New York* 10701

An investigation of the interactions of soil microorganisms and a group of chlorinated aromatic herbicides will be made. Specific objectives will be: (1) to isolate and characterize microbial species responsible for complete or partial herbicide degradation, (2) to characterize in relatively simple culture media the rates of degradation of this group of structurally related herbicides, (3) to study the influence of environmental factors such as clay, supplemental substrates, oxygen and pH levels and previous adaptation to structurally similar compounds, (4) to identify the routes of degradation and fate of degradation products, and (5) to determine if microorganisms capable of rapidlyy degrading a herbicide can be used to decontaminate soil and water.

Results from these studies should be helpful in the future design of molecules useful as herbicides but which will be degraded rapidly before they have an opportunity to pollute soil and water.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P.

4.0154, PLANT RESPONSE TO ORGANIC CHEMICALS IN THE ROOT ENVIRONMENT

F.T. CORBIN, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC03083)

OBJECTIVE: Develop the principles concerning the uptake of organic chemicals by plant roots. Determine the degree to which herbicide susceptibility varies in the species Arachis hypogea.

APPROACH: Previous work in this laboratory has shown that dark grown excised barley roots do not markedly take up or affect organic chemicals unless they contain an aldehyde group. Attempts will be made to determine the nature of the aldehyde-root interaction. The possibility that acid conversion or microbe breakdown may be involved will first be considered. Next, the possibility of a real uptake phenomena will be pursued. Different types of root systems will be studied to select one which is more responsive to organic chemicals. For the peanut mutant work, a comparison will be made between field and laboratory techniques for estimating herbicide tolerance.

PROGRESS: The influence of microorganisms on the detoxication of 2-methoxy-3,6-dichlorobenzoic acid (dicamba) and 3-amino-2,5- dichlorobenzoic acid (amiben) was investigated. An actinomycete, in monoculture, decarboxylated COOH labeled dicamba in soil and vermiculite media. There is indication for a co-oxidation of dicamba without enrichment of active organisms. Decarboxylation of dicamba by the actinomycete was enhanced by the presence of a penicillium in the growth medium. Dextrose and dextrose containing media decreased the phytotoxicity of Amiben to cucumber seedlings. Phytotoxicity was reestablished when microbes were grown in the media. These studies contribute to our knowledge concerning mechanisms of interactions between herbicides, plants, and microorganisms.

SUPPORTED BY U.S. Dept. of Agriculture

4.0155, MOVEMENT OF HERBICIDES OFF, INTO AND THROUGH SOILS

P.C. KEARNEY, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (0710-08-05(C))

OBJECTIVE: Determine the lateral and vertical movement in soils of known physical, chemical, and mineralogical properties of several herbicides differing in physical and chemical properties.

APPROACH: The presence of herbicides in and on soil surfaces caused by lateral and vertical movement will be determined in a well defined watershed with detailed past information on cropping history, fertilizer treatments, soil physical properties, climatic conditions, and hydrological data. Herbicides in soil and water samples will be assayed using appropriate analytical methods, including colorimetric, spectrophotometric and gas

chromatographic procedures. All data will be subjected to appropriate statistical analyses, and correlated with the soil and climatic data pertaining to the areas receiving herbicide applications.

PROGRESS: This project was initiated in 1967 to study (a) movement of picloram, 2,4-D, 2,4,5-T, and dicamba in surface and ground water and (b) distribution and persistence of the herbicides in soil. Water samples collected from flumes at the base of each watershed during and after rain storms in 1967 contained 2,4-D, but concentrations of picloram and dicamba were below the limits of detection. The highest concentration of 2,4-D was 28 ppb. After the 1969 applications, 2,4,5-T was detected in water samples taken at the base of watershed 2 during the first and second storms. The highest concentration was 48 ppb. Herbicides were present in surface runoff water collected at the base of the 0.05-acre plots. In 1968 concentrations in surface runoff at the base of the small plots were 1224, 583, and 229 ppb for 2,4-D, 2,4,5-T, and picloram, respectively. Highest concentrations of the herbicides in surface runoff at the base of the small plots were found in 1969 when the application rate was 4 lb/A. Samples taken after the first storm causing significant runoff contained the highest concentrations. These were 1882, 681, and 4187 ppb for 2,4-D, 2,4,5-T, and picloram, respectively.

4.0156. INACTIVATION AND LOSS OF PESTICIDES FROM SOIL

S.B. WEED, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC01062)

OBJECTIVE: Determine mechanisms of inactivation and loss of pesticides by/from soil colloids by studies of retention and release, movement of water through soil, non-biological degradation.

APPROACH: Retention and release of selected pesticides by reference inorganic and organic adsorbents studied as functions of adsorbent type, complementary ions and molecules, pH, and solution composition using adsorption isotherms, column chromatography, etc. Analytical techniques include X-ray diffraction, infrared adsorption, and D.T.A. Movement of pesticides studied using soil columns and related to soil properties and pesticide characteristics. Nonbiological degradation of pesticides studied as a function of adsorbent type, chemical environment, moisture content, etc. System will be treated for removal of all biological effects on degradation.

PROGRESS: 1. Diquat adsorbed by montmorillonite is not herbicidally active until the amount absorbed approaches the clay CEC. Inorganic cations (K, Cs, Ca, Mg, Ba, Al) do not effectively exchange adsorbed diquat, and presence of these ions in the growth medium does not increase diquat availability. However, addition to the growth medium of an organic cation (N-(4-pyridyl) pyridinium chloride) capable of desorbing diquat from montmorillonite makes the diquat available to plants. 2. Malathion adsorbed by montmorillonite saturated with polyvalent inorganic cations is readily recovered by extracting the aqueous suspension with CCl_4. Clay saturated with monovalent cations retained part of the malathion, suggesting that bonding directly to the cation is less readily broken than a water-bridge bond. 3. CO and PO groups are actively involved in bonding of organophosphates to montmorillonite. No evidence was found for bonding through the PS group. 4. Adsorption of monuron and fenuron to Ca-montmorillonite decreased but did not prevent their release to dilute $CaCl_2$ equilibrating solutions. Monuron was more readily removed than fenuron. 5. The results suggest that adsorption via coulombic attraction may inactivate organic herbicide molecules, adsorption via less energetic bonds may at most decrease the tendency to move. These findings help explain the fate of pesticides added to soils.

SUPPORTED BY: U.S. Dept. of Agriculture

4.0157. CHEMISTRY OF ADSORPTION OF PESTICIDES ON SOIL SILICATES

S.B. WEED, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC01061)

OBJECTIVE: Determine the effect of site and magnitude of structural charge of soil 3-layer silicates on the adsorption and retention of selected organic pesticides. Determine the effects of inorganic cation population, pH (as related to exchangeable H and Al), and complementary organic molecules on the retention of selected organic pesticides by layer silicates. Determine the nature of the bond between the adsorbed pesticide and the layer silicate. Investigate the catalytic degradation of adsorbed organic pesticides. Determine the relative toxicity of adsorbed vs. 'free' pesticides.

APPROACH: Construction of adsorption isotherms. X-ray diffraction studies of basal spacings of layer silicates as related to amount of the pesticide adsorbed and the ambient relative humidity. Infra-red studies of free and adsorbed pesticides will be made. Determine suitable chromatographic and tracer techniques to be used. Utilize suitable test organisms to evaluate effects of adsorption on activity of selected pesticides.

PROGRESS: Malathion was adsorbed in the interlayer space of montmorillonite saturated with Na, K, Cs, Mg, Ca, Sr, Ba, Al, or Li. The adsorption mechanism for the air-dry systems was bonding directly between the carbonyl oxygen and the monovalent cations, while a water bridge was involved in the case of the polyvalent cations. Malathion in water diffused across a separating fritted glass membrane and was adsorbed by montmorillonite in suspension in approximately a 1:1 molar ratio, calculated on an exchangeable cation basis. Adsorbed malathion was readily recovered by extracting the aqueous clay suspensions with carbon tetrachloride. There was no evidence for degradation of the malathion. Diquat and paraquat were competitively adsorbed on a series of micas and collapsed vermiculites. A positive linear relationship between the equivalent fractions of diquat adsorbed (q/q(o)) and the surface charge densities of the adsorbents was confirmed. A similar study using a series of montmorillonites yielded a positive linear relationship between (q/q(o)) and CEC. The results thus indicate that the relative energy of adsorption as well as the amount of material adsorbed is affected by the clay charge.

SUPPORTED BY: U.S. Dept. of Agriculture

4.0158. PHYSIOLOGY AND CONTROL OF WITCHWEED IN CORN

G.H. EGLEY, U.S. Dept. of Agriculture, Crops Research Division, *Waterville, North Carolina* 28472 (0710-01-17)

OBJECTIVE: Discover more efficient chemical and/or cultural methods of selectively controlling witchweed in crops. Obtain a basic understanding of witchweed physiology, seed germination and seed dormancy so that better witchweed control methods may be developed and effectively used.

APPROACH: Conduct greenhouse and field tests to discover herbicides that control witchweed selectively in crops. Characterize persistence of selected herbicides in the soil. Discover methods of selectively stimulating or inhibiting germination of witchweed seeds. Determine physical and biological factors contributing to witchweed seed dormancy and seed longevity.

PROGRESS: Seed of the angiospermous root parasite, Striga lutea, are normally dormant, but they usually germinate under favorable conditions of temperature and moisture when exposed to exudates from certain plant roots or to ethylene gas. Since seedlings die in the absence of a gramineous host, we are investigating the stimulation of seed germination in the absence of a host as a means of controlling this obligate parasite of corn. Under ideal conditions, as little as 0.1 lb/A of ethylene induces germination of witchweed seed in the greenhouse, and corn, cotton, and garden peas were not injured by injection of 1 to 20 lb/A of ethylene gas into soil before planting the crops, or into soil around 14-day old plants or germinating seed of the crops. One year after applying 8 lb/A of pyrichlor on the soil surface the soil contained herbicide residue injurious to soybeans at depths down to 12 inches at each location. On plots treated with 8 lb/A of picloram, herbicide residues toxic to soybeans occurred in soil from all depths down to 60 inches. In plots treated with 8 lb/a of 2,4-D, no residue toxic to soybeans was found in soil at any depth down to 60 inches.

4. PESTICIDES

SUPPORTED BY U.S. Dept. of Agriculture

4.0159, EFFECTS OF ORGANIC PHOSPHATE INSECTICIDES ON MICROBIOLOGICAL PROCESSES AFFECTING SOIL FERTILITY

B.R. FUNKE, North Dakota State University, Agricultural Experiment Sta., *Fargo, North Dakota* 58103 (ND-H-08-006)

OBJECTIVE: Determine the effects of organic phosphorus insecticides on nutrification, nitrogen fixation, ammonification, etc. Isolate the organisms capable of degrading these compounds and determine: metabolism of the compounds, and possible toxic effects of the metabolites on soil processes.

APPROACH: Nitrification, nitrogen fixation, etc. will be determined by in vitro and greenhouse methods. Effects of insecticide concentrations and various environmental conditions will be investigated. Organisms capable of degrading these compounds will be isolated by enrichment techniques and attempts will be made to identify the metabolites.

PROGRESS: Completed work on survey of nine organophosphate and three carbamate insecticides on nitrification, legume growth, and on growth of pure cultures of several Rhizobium sp. Nitrification: None of the insecticides significantly inhibited nitrification at 5 or 50 ppm. At 500 ppm Dyfonate, Bayer 68138, Bayer 37289, Dursban, Temik and Baygon caused at least some inhibition. Inhibition by Temik and Baygon almost 100% at 500 ppm and nitrites accumulated for several days. Legumd growth: The carbamates Baygon, Furadan, and Temik were strongly inhibitory to legume development, particularly at 50 and 500 ppm. Among the organo-phosphates only Dursban approached them in phytotoxicity. Alfalfa and sweetclover were the test plants, grown in plastic growth pouches. Little significant effect on growth was observed with the remaining insecticides, at least at 5 and 50 ppm. Disc Inhibition: Four Rhizobium species were tested. The most inhibitory insecticides were Baygon, Temik, Bayer 37289, Trichlorfon, Bayer 68138, and Dasanit. The least were Dursban, Carbophenothion, and Diazinon. Began preliminary work to investigate in detail the severe effect of some of these insecticides on nitrification and reasons for nitrite accumulation.

SUPPORTED BY U.S. Dept. of Agriculture

4.0160, ENCAPSULATION OF INSECTICIDES AND VIRUSES FOR CONTROL OF INSECTS

J. BAKAN, Natl. Cash Register Company, *Dayton, Ohio* 45409 (00ENTCO5173709CO)

OBJECTIVE: Determine through research the feasibility of controlling insects using encapsulated formulations of insecticides and virus.

APPROACH: Using established patented encapsulated procedures, prepare insecticide and virus formulations which release their content at a uniform rate over a period of from one to six weeks.

PROGRESS: Studies indicated that formulations involving encapsulation of insecticides and viruses delayed release of these materials under field conditions and gave promise as a technique for use in control of insect pests. Capsules of malathion with slow release rates persisted on foliage of plants up to 4 months with little loss of the malathion. Encapsulated malathion was also maintained in wet soil indoors for almost a year with little insecticidal loss. Tests on ants indicated that control can be achieved far beyond the usual life expectancy of the insecticide. Field tests were conducted against the European corn borer, alfalfa weevil, corn earworm, cotton bollworm, corn rootworm, and grasshoppers. Considerable worthwhile information was obtained on application techniques and behavior of microcapsules under field conditions.

SUPPORTED BY U.S. Dept. of Agriculture

4.0161, BIOLOGICAL SOIL COMPONENTS DETERMINING PERSISTENCE AND DETOXIFICATION OF BIOCIDES

J.Q. LYND, Okla. St. Univ., Agricultural Experiment Sta., *Stillwater, Oklahoma* 74075 (OKL01244)

OBJECTIVE: Determine soil biological parameters governing pyridyl biotoxic transformations and degradations with soil types representative for key soil orders.

APPROACH: Soil microfloral association isolates active in soil pyridyl degradation transformations will be attained through enrichment culture techniques with governing soil biological interactions determined for controls in rates and magnitude of pyridyl biotoxic diminution. Bench mark soil factors and microfloral interactions will be computerized in correlation for projecting soil biological controls to ranges in soil and climate conditions.

PROGRESS: Parameters were identified for soil transformations of chlorinated pyridine phytoxicity to Robinia pseudoacacia. Indicator plant aberrations at threshold herbicide levels were established with Cucumis sativa for the pyridyls. Least squares computerized statistical procedure was developed correlating 'Bench-mark' soil characteristics for establishing soil biological controls determining pyridyl bioactivity and degradation. Four common, ubiquitous soil microfloral associations dominated by the genera: Aspergilli, Trichoderma, Mucor, and Penicillium, significantly altered and degraded bipyridyl biotoxins. Vector magnitudes and rates of bioactivation with eventual detoxification were greatly influenced by soil epipedon characteristics including texture, clay type, pH, organic amendment composition, temperature, and biotoxin concentration. Defined presynthesized growth factors: indole, picolinic acid, tryptophan, and yeast extract ameliorated pyridyl fungitoxicity.

SUPPORTED BY Oklahoma State Government

4.0162, BEHAVIOR OF SPECIFIC HERBICIDES IN PLANTS AND SOILS

P.W. SANTELMANN, Okla. St. Univ., Agricultural Experiment Sta., *Stillwater, Oklahoma* 74075 (OKL01324)

OBJECTIVE: Determine the effects of climatic and edaphic factors on movement, persistence and toxicity of herbicides in the soil.

APPROACH: Soil characteristics determining the effect of biological decomposition, absorption, volatilization, and leaching on the phytotoxicity and persistence of the herbicides in Southwestern soils will be evaluated. The persistence under field conditions will be determined on two contrasting representative soil types used in cotton and grain sorghum production. Dissipation studies using controlled temperature and humidity cabinets and the greenhouse will include soil variables of moisture tension, organic amendments, pH, temperature, and fertility level. Using basic hydrodynamic and chromatographic models, information will be provided for describing the mixing of the herbicides in a soil-water system. Using field sited and controlled methods for altering the soil-water redistribution a relationship between the volume of water applied and the amount of herbicide moved will be studied.

PROGRESS: A cooperative regional soil bioassay technique experiment was developed and evaluated. No one assay evaluation procedure was uniformly best. The influence of CaCl(2) concentration on the mobility and adsorption of prometryne and fluometuron was studied. Calcium saturated loamy fine sand and loam soils were used. More fluometuron was adsorbed in the presence of 0.01 N than 0.5 N CaCl(2) in both transient and adsorption isotherm systems. Prometryne adsorption was greater in the presence of 0.5 N than 0.01 N CaCl(2) in both soils. Prometryne mobility was retarded, owing to adsorption, in the presence of 0.5 N CaCl(2). The influence of soil textural stratification on the movement of fluometuron was studied. The texturally stratified soil columns showed significant differences in the relative fluometuron concentration distribution. Not all textural stratifications gave a difference and the results did not relate to total porosity differences between the two soils. The greater the pore size range in the second soil of the stratification the greater mixing and early arrival of the herbicide in the effluent.

SUPPORTED BY U.S. Dept. of Agriculture

4.0163, APPLICATION OF AGRICULTURAL CHEMICALS

G.E. PAGE, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00502)

OBJECTIVE: Study factors which influence either drift or proper placement of agricultural chemicals; develop methods and equipment for more effective incorporation of soil active herbicides; develop methods and equipment for more effective control of symphylans, nematodes, and soil borne insects and plant disease; develop and test equipment for application of insecticides and fungicides where a special need exists due to lack of adequate equipment for control on a particular crop; develop equipment for application of polyhedrosis virus for cutworm control.

APPROACH: Laboratory and field tests will be conducted to determine effect of physical properties (viscosity, density, etc.) of spray solutions on drift and distribution patterns. Soil incorporation studies will be continued to determine optimum incorporation equipment for various herbicides and crops. Continue work on soil fumigation practices and equipment with special interest on established crops (mints and berries) in Western Oregon and annual crops in Eastern Oregon.

PROGRESS: The Lilliston rolling cultivator is almost equal to the Howard rototiller for the incorporation of Roneet and Trifluralin herbicides into a prepared seed bed for weed control in sugar beets. The Lilliston rolling cultivator did not work well under light sod conditions for incorporation of Nitralin and Trifluralin in apple orchard. In soil treatments over 20 percent of Zinophos and Dyfonate was lost prior to incorporation into the soil.

SUPPORTED BY: Oregon State Government

4.0164, BEHAVIOR OF CHEMICALS INTRODUCED INTO THE FOREST ENVIRONMENT AND THEIR IMPACT ON THE ECOSYSTEM

R.F. TARRANT, Oregon State University, U.S.D.A. Pac. Nw. Forest Sta., *Corvallis, Oregon* 97331 (PNW1603)

OBJECTIVE: Elucidate the manner in which chemicals behave in various parts of the forest environment and their impact on the biota, in solving problems of environmental pollution connected with forest use of economic chemicals.

APPROACH: Develop information leading to better understanding of the principles of chemical behavior in the forest environment; through the use of mathematical models, predict the behavior of a given chemical in a given environment; and assess the impact of chemicals on living organisms.

PROGRESS: The systemic insecticide, phorate, persists in a forest environment for as much as 18 months. Tannin content of Douglas-fir bark used as a mulch is not harmful to soil microbes. Tree barks have a number of potential uses in agriculture and are chemically and physically adaptable to beneficial utilization. Herbicide residues in fall runoff from treated lands are greatest when the chemicals are applied in late summer and the first fall storms are of high intensity. Relative rates of degradation of phenoxy herbicides and picloram are not influenced by starting concentration. Amitrole, 2,4-D, 2,4,5-T, and picloram are degraded in forest floor material but at markedly different rates. Primary root elongation is inhibited and abnormal lateral root proliferation is observed in two-day-old pea seedlings treated with a variety of herbicides. A soluble cytoplasmic protein associated with zones of meristematic activity or tissue expansion has been found in roots of pea seedlings. A method has been developed to isolate this protein by ammonium sulphate fractionation and preparative scale gel electrophoresis. No appreciable movement of DDT from forest floor to mineral soil was observed after aerial application of the chemical. Picloram herbicide had no significant effect on microbial activities in three soils of different characteristics. Nitrogen in avalanche debris has been shown to develop as a result of nitrogen fixation by Sitka alder.

SUPPORTED BY: U.S. Dept. of Agriculture

4.0165, PESTICIDE MOBILITY AND DEGRADATION IN SOIL-WATER SYSTEMS

V.V. VOLK, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00873)

OBJECTIVE: Identify and characterize the physical-chemical properties of the pesticide-soil-water system which are pertinent to (i) pesticide transport through the soil in infiltrating water, and (ii) pesticide desorption from eroded soil into surface waters. Develop mathematical model(s) which will provide semiquantitative prediction of pesticide movement in soil-water systems based on input data obtained.

APPROACH: Oregon soils with known chemical and physical properties will be leached with water solutions of 2,4-D, 2,4,5-T, and picloram. Upon leaching, the movement of the herbicide will be ascertained through radioisotope assay. As an aid to interpretation of the results of the movement studies, adsorption and desorption isotherms will be prepared for the same soils and chemicals. Having obtained the distribution of a chemical through the soil column as a function of leaching, soil, and chemical variables, an attempt will be made to relate results to a mathematical model used to predict movement. The relative importance of soil and chemical variables considered in the model will be adjusted so that chemical movements in a soil profile may be made.

PROGRESS: The movement and adsorption of 2,4-D acid in selected Oregon soils were studied as a function of pH, organic matter, and the presence of acidic cations. A decrease in the movement and an increase in adsorption of 2,4-D acid could be induced by the presence of Fe , and Cu cations on the exchange sites. The reduced 2,4-D mobility was attributed predominantly to the decreased pH of the soil with acid cation saturation. However, evidence was observed to indicate the formation of a complex between the 2,4-D and the hydrated Fe, Al, and Cu. Equilibration of the natural and the Fe, Al, and Cu saturated soils with 50 ppm of 2,4-D at 25 C for 24 hours showed the 2,4-D adsorption to decrease in the following order: Fe-soils, Al, Cu-soil, natural Lookout silt soil. Water solubility of the 2,4-D salts of Fe, Al, and Cu increased from 195 to 354 to 1069 ppm respectively. The effects of pH and extractable aluminum on the 2,4-D adsorption appeared to indicate that adsorption was directly associated with the degree of dissociation of the 2,4-D acid as governed by the pH of the system.

4.0166, PESTICIDE DETOXICATION MECHANISMS OF MICROORGANISMS IN SOIL AND WATER

J.M. BOLL, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01761)

OBJECTIVE: Observe the response of microorganisms in soil and water to specific pesticides; evaluate microbial activity by product identification; establish mechanism of detoxication.

APPROACH: Microbes from soil and water will be cultured and exposed to specific pesticides. Product identification will be by chromatographic, spectrophotometric and other procedures.

PROGRESS: The decomposition of the pesticide Sevin, 1-naphthyl N- methylcarbamate, was investigated with several microbial isolates from soil. Its transformation was followed periodically by different chemical methods. It could be established that all the isolated microorganisms hydrolyzed Sevin to 1-naphthol. A fungus, identified as Fusarium solani, metabolized 1-naphthol rapidly, whereas one bacteria, a gram negative coccus, degraded the hydrolysis product gradually and a third isolate, a gram positive rod, accumulated it. Since 1-naphthol was identified as a metabolic product, its C-ring labeled form was added to the growth medium and the disappearance of radioactivity compared with that of the side-chain labeled C-Sevin. F. solani decreased the radioactivity of the labeled Sevin almost completely whereas only 20% of the radiocarbon from 1-naphthol disappeared, but the remaining radioactive compound constituted a new product. The bacterial coccus, however, was active in degrading the radioactivity of the ring labeled 1-naphthol but a considerable amount of the radiocarbon from the metabolized Sevin remained in the medium. The mixed culture of the two microbes was very effective in degrading Sevin as well as 1-naphthol and this suggests that complete biodegradation is performed in combined growth. Studies have been initiated in order to determine the microbial decomposition of metobromuron and maloran. Tentative evidence was received that the two ureas are degraded to the corresponding anilines.

4. PESTICIDES

4.0167, PHYSICAL-CHEMICAL ASPECTS OF PERSISTENCE AND MOVEMENT OF HERBICIDES IN SOIL
J.K. HALL, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01663)

OBJECTIVE: Relate persistence and movement of herbicides to the physical, chemical and mineralogical characteristice of soil types in Pennsylvania. Determine by bioassay and chemical analyses the effects of soil properties and climatic conditions on the minimum soil solution concentrations of different herbicides which are toxic to crop species. Determine the adsorption of herbicides on the colloidal soil constituents. Determine the effect of herbicide residues in soils on nutrient uptake by crops.

APPROACH: Analysis of herbicide residues in soil, water and plant tissue will be carried out by bioassy, UV-adsorption spectrophotometry, and gas chromatography. Nutrient solutions and clay cultures will be used to grow plants in a growth chamber to determine the minimum soil solution concentrations of different herbicides which are toxic to crop species. Infrared absorption spectrophotometry, x-ray analysis and various chemical techniques will be used to study the adsorption of herbicides by pure and soil clay minerals. Uptake of soil nutrients by plants, grown in soils to which a range of herbicide concentrations have been applied, will be measured in greenhouse experiments.

PROGRESS: Losses of atrazine from a Hagerstown silt loam of 8% slope related to rainfall and rates of application of pesticide. Total atrazine concentrations in runoff water in 1967 were 0, 0.77, 1.54, 1.60, 3.39, 5.65 and 7.78 ppm from plots treated with 0, 0.5, 1.2, 4, 6, and 8 lb./A of atrazine. Concentrations in eroded soil the same year were 0, 0.49, 2.16, 8.57, 14.56 and 19.54 ppm, respectively. Atrazine was detected in three collections (3/9) of runoff water in 1968, total ranging from 0.05 to 0.15 ppm. Concentrations in eroded soil were again higher than runoff water at all rates but less than 1967 values. Soil core samples collected at intervals each year indicated that the percentage of applied atrazine decreased from 87% in June, 1967 to 27% in Sept. 1967, and from 19% in Apr., 1968 to 5% in Sept. 1968. Total losses of atrazine in 1967 were 1.05 lb/A (runoff water) and 0.59 lb/A (eroded soil) which equaled 4.9 and 2.7 percent of the total applied. Losses in runoff water and soil in 1968 amounted to 0.02 and 0.04 percent, respectively.

4.0168, REPLACEMENT OF CULTIVATION WITH CHEMICALS
W.E. LARSON, Coll. of Agriculture, *Wroclaw, Poland* (E21-SWC-12)

OBJECTIVE: Influence of replacement of mechanical tillage with herbicides on crop yields and soil properties.

APPROACH: Five treatments consisting of tillage and weed control chemicals at two levels of fertilizer on four crops at two locations are being studied near Wroclaw, Poland. Visual observations of development of crop plants and weeds, as well as quantitative measurements of emergence, growth and yield of the economic product and foliage and roots of plants will be made. Water content, porosity, soil strength, aggregation, microstructure, and other physical properties of the soil will be made. Assimilable phosphorous, potassium, magnesium, and calcium, nitrogen, organic matter and soil reaction will be made. Soil content of herbicides, free amino acids, azotobacter, papillary bacteria, algae, and soil mesofauna will be determined periodically. Other plant and soil measurements will be made as the need arises.

PROGRESS: The experiment is proceeding according to the research plan. The experimental areas have been well characterized; however, few data will be available for another six months.

SUPPORTED BY U.S. Dept. of Agriculture

4.0169, THE DISPOSITION OF PESTICIDES IN THE SOIL
H.D. DUBEY, Univ. of Puerto Rico, Agricultural Experiment Sta., *Mayaguez, Puerto Rico* (PR00189)

OBJECTIVE: Determine the physical, chemical, and biological processes, and soil characteristics which are important in the disposition of pesticides in soils.

APPROACH: Soil samples from different agricultural regions of the Island will be treated with different pesticides and incubated for varying periods. Effect of pesticides on the beneficial soil microbiological processes will be studied by changes in the relative microbial population, microbial respiration, nitrification, nitrogen fixation, and sulfur oxidation. Influence of physical and chemical soil properties, pH, moisture, and temperature on these processes will be studied in soils treated with pesticides. Pesticides to be studied initially are Di-syston, diuron, ametryne, 1,2-dibromomethane and maneb.

PROGRESS: Effect of fungicides dyrene and manzate alone and in combination (1:1 ratio) at rates from 15 to 960 ppm on nitrification, nitrogen mineralization, microbial population were studied in a lateritic soil and an alkaline alluvial loam, by the incubation method for a period of 16 weeks. Manzate was more inhibitive of nitrification than dyrene. Soil type influenced this effect, inhibition was more pronounced in the slow nitrifying lateritic soil than in the fast nitrifying loam. Inhibition persisted for more than 16 weeks at higher rates of application. There was no synergistic effect on nitrification inhibition when the two fungicides were applied in 1:1 ratio. Persistent effect on nitrogen mineralization was noticed only at 960 ppm, irrespective of soil type. Fungi and actinomycetes were reduced, but bacteria were increased by these fungicides. Soil type influenced the degree of this response, the effect of dyrene was more pronounced in the acid lateritic soil and that of manzate in the alluvial loam. Manzate caused qualitative and quantitative change in the fungal population of the loam. Sugarcane stunting on an alkaline alluvial loam was caused by repeated applications amounting to about 80 lb/A or dyrene, manzate and zineb to the preceding tomato crop. The microbiological equilibrium of the soil was upset, nitrogen mineralization and nitrification were adversely affected, resulting in nonavailability of nitrogen to the crop. By application of mineral nitrogen to the affected soil normal healthy plants were obtained.

SUPPORTED BY U.S. Dept. of Agriculture

4.0170, CLIMATIC AND SOIL FACTORS INFLUENCING HERBICIDE ACTIVITY AND PERSISTENCE
L.C. LIU, Univ. of Puerto Rico, Agricultural Experiment Sta., *Mayaguez, Puerto Rico* (PR00147)

OBJECTIVE: Develop background information on herbicidal activity under various climatic, edaphic and microbial conditions of Puerto Rico.

APPROACH: Studies will be carried on to determine the influence that certain climatic conditions (sunlight, temperature, rainfall, etc.) and different soil properties (texture, organic matter, quantity and type of clay minerals, pH and cation exchange capacity) may have upon the persistence, penetration, effectiveness, toxicity to crop plant and activity of herbicides. Some phases of the above outlines work will be carried in the greenhouse while others will be performed under field conditions or both.

PROGRESS: Two separate studies were conducted to determine the adsorption characteristics of ametryne and diuron in the soil and the persistence of ametryne, diuron, fluometuron, norea, prometryne, and terbacil in a Mabi clay soil treated 13 months ago. The results of the adsorption study indicate that the various soils differed greatly in their capacity to adsorb ametryne and diuron. The Cano Tiburones soil was found to be the most adsorptive and the Toa sandy loam the least. Adsorption by other soils was between these two extremes. In general, diuron was adsorbed to a greater degree than ametryne. In the second study, herbicide residues at the 0-4 inch depth were found to be relatively low in plots treated with 4 pounds per acre of either ametryne, diuron, fluometuron, norea, and prometryne or 2 pounds per acre of terbacil. Residues were found to increase in the 0-4 inch depth as the herbicide rate was raised. Thus, fluometuron and diuron were detected at rather high concentration when applied at 16 and 32 pounds per acre. At the corresponding rates, only small to moderate amounts of ametryne, norea, prometryne, and terbacil were detected.

SUPPORTED BY U.S. Dept. of Agriculture

4.0171, MECHANISM OF ADSORPTION OF VARIOUS HERBICIDES BY SOIL HUMIC SUBSTANCES

G.T. FELBECK, Univ. of Rhode Island, Agricultural Experiment Sta., *Kingston, Rhode Island* 02881 (RI00008)

OBJECTIVE: Determine functional groups on soil humic substances responsible for adsorption of herbicides, kinetics of adsorption and desorption of herbicides by soil humic substances, and examine effect adsorption has on activity and persistence of herbicides in soil with goal of improving methods of reducing persistance after herbicidal requirements have been met.

APPROACH: Soil O.M. to be fractionated by solubility and chromatographic techniques and effects of various fraction on adsorption and desorption of herbicides determined, using 1 - labeled materials. Kinetics of adsorption to be examined mathematically by adaptation of enzyme systematics. Greenhouse and field experiments based on consideration of 1 and 2 above, to study effects of various O.M. amendments on herbicide persistance and toxicity.

PROGRESS: A study of the chemical hydrolysis of atrazine (Atr) catalyzed by soil organic matter fractions was carried out in 95% ethanol (EtOH) using the EtOH-insoluble fraction of humic acid. The reaction followed first order reaction kinetics for the first 40% of the hydrolysis, with a curvature appearing in the reaction plot as the hydrolysis continued. In equimolar solutions of Atr and hydrolyzed atrazine (AtrOH), the presence of AtrOH unhibited the hydrolysis of Atr to the extent of 16% over pure Atr mixtures in a period of 21 days. Adsorption studies indicated that the adsorption of AtrOH was much greater than Atr by humic acid at equimolar concentrations. Desorption studies with 95% EtOH, aqueous Ca(OAc)2, and aqueous Ba(OH)(2) indicated that all three reagents were about equal in the desorption of Atr, but that the desorption of AtrOH by Ba(OH)(2) was twice that of Ca(OAc)(2). Very little AtrOH was desorbed by 95% EtOH. These data suggest that Atr reacts only with the COOH group of the humic acid complex, but that AtrOH may be adsorbed by both the COOH and GH groups. Further studies to clarify this point are currently underway.

SUPPORTED BY U.S. Dept. of Agriculture

4.0172, TURFGRASS WEED CONTROL

J.A. JAGSCHITZ, Univ. of Rhode Island, Agricultural Experiment Sta., *Kingston, Rhode Island* 02881 (RI00232)

OBJECTIVE: Develop sound recommendations for selective and safe herbicidal elimination of various weeds from turfgrass stands and to determine the response of germinating turfgrass seed and seedlings to these herbicides. Determine whether herbicide resistant strains of common dandelion exist and to study the growth habits of this plant. Develop bioassay methods for determining the presence and levels of herbicidal soil residues. Investigate effects of soil residues of herbicides on growth of established turfgrass and chemical methods for eliminating harmful or objectionable residues.

APPROACH: Pre- and post-emergence herbicides will be evaluated on fine turf, lawn and utility turfgrass. Inconsistancies in control of common dandelion will be investigated by making detailed studies of the species and its associated growing conditions. Soil herbicide residues will be evaluated at different time intervals by means of bioassay techniques and by studying effects on growth of turfgrass.

PROGRESS: Preliminary studies indicate that in established turf chemical preemergent control of dandelion, mouseear chickweed and broadleaf plantain may be feasible. Preemergent control of crabgrass was obtained with half rates of bandane, bensulide, DCPA, nitralin and siduron in the second year after use at full rates. Results were fair with DMPA and terbutol and poor with benefin. Experimental herbicides which appeared promising for preemergent, crabgrass control were as follows: CP-53619, D-292, NC-5651, M-3251 and RP-17623. Results with MF-415, MF-416 and VCS-438 were discouraging. Good control of annual bluegrass was obtained in putting-green turf after four annual applications of bensulide, tricalcium arsenate and lead arsenate. Ethrel, maleic hydrazide and MF-415. MF-416 are promising chemicals to prevent annual bluegrass seed formation and possibly reduce potential infestation.

SUPPORTED BY U.S. Dept. of Agriculture

4.0173, USE OF FENURON IN CONTROL OF SCRUB OAK

N.B. GOEBEL, Clemson University, Agricultural Experiment Sta., *Clemson, South Carolina* 29631 (SC00579)

OBJECTIVE: Ascertain the minimum dosage of fenuron needed to effectively control undesirable hardwoods prior to reforestation.

APPROACH: Fenuron pellets will be broadcast in selected hardwood stands at rates of 5, 10, 20 and 40 pounds per acre, six months prior to fall planting of loblolly pine. Evaluation of kill is recorded for species, density, size as affected by rate of application.

PROGRESS: Fenuron was applied to Piedmont scrub oak stands at rates of 5, 10, 20 and 40 pounds per acre. One year later, and for four consecutive years, loblolly pine was interplanted as a test for presence of residual fenuron in the soil. The effectiveness of the fenuron in controlling scrub oak will be analyzed. Survival counts of the loblolly pine plantings will also be made. Inactive this period. Survival and growth of interplanted seedlings remains to be checked, after which a final report will be prepared.

SUPPORTED BY South Carolina State Government

4.0174, THE DISPOSITION OF PESTICIDES IN THE SOIL

C.E. RIECK, Clemson University, Agricultural Experiment Sta., *Clemson, South Carolina* 29631 (SC00822)

OBJECTIVE: Determine the physical, chemical, and biological processes, and soil characteristics which are important in the disposition of pesticides in soils.

APPROACH: Studies will be made of the physical, chemical, and biological processes, together with soil characteristics which are important in the disposition of pesticides in South Carolina soils. Particular emphasis will be directed to soil reaction and the concentration of exchangeable cations on the colloids and in the equilibrium solution as affecting molecular structure, mobility, phytotoxicity, rate of inactivation, and vaporization of important pre- emergence herbicides and foliar-applied insecticides used on Piedmont and Coastal Plain agricultural soils. Since it is virtually impossible to ignore physical and biological soil characteristics, effort will be made to evaluate their interactions with the chemical phase of the problem, when this necessary. Some effort will be directed toward relating extractable soil-contained pesticides with biocidal activity to provide a possible diagnostic tool and to relate fixation and degradation to persistence.

PROGRESS: The effects of soil microorganisms on 4-(methylsufonyl- 2,6-dinitro-N,N-dipropylaniline (Nitralin) were investigated in growth chamber and laboratory experiments. Soil fungi were isolated from several Piedmont soils that had been enriched with Nitralin. These heterotrophic organisms were able to utilize Nitralin as their sole source of Sulfur. They were not able to utilize the herbicides as a carbon source. Soil incubation studies have shown that to obtain maximum phytotoxicity with Nitralin there is an indefinite time period (5-10 days) in which the herbicide must be in the soil. These studies indicate that a metabolite may be more phytotoxic than the parent molecule.

SUPPORTED BY U.S. Dept. of Agriculture

4.0175, WEEDS AND WEED CONTROL

J.F. STRITZKE, South Dakota State University, Agricultural Experiment Sta., *Brookings, South Dakota* 57006 (SD00032)

OBJECTIVE: Develop practical methods of controlling weeds in cultivated land, grassland or other uncultivated land. Improve and develop cultural methods of control, chemical methods of control, develop methods of control that utilize chemicals and cultural practices. Investigate new chemicals that indicate they have herbicidal properites. Study physiological, morphological and agronomic responses of weeds and agronomic crops to herbicides; factors affecting crop yield. Biochemical response of weeds. Determine differences in growth habits, means of propagation and physiological activity of weeds. Study factors affecting activity of vegetative buds, development, maturation and germination of weed seeds.

4. PESTICIDES

APPROACH: Research included studies of combinations of crops, chemicals and cultivation to eliminate and prevent reinfestation of leafy spurge and Russian knapweed; studies on the use of barban and avadex for wild oats control inflax, wheat and barley; studies of chemicals for pre-emergence weed control in corn and soybeans; screening tests of 6 to 8 new chemicals on 7 species of noxious weeds at 3 dates and 21 locations.

PROGRESS: A four-year study on persistence and soil movement of picloram has been completed. Picloram used at 1/2 to 3 lb/A was found to leach through the soil profile vertically and longitudinally and some picloram was present throughout the soil profile 3 years after treatment. Results of a four-year study for wild buckwheat control indicate that excellent control of wild buckwheat is possible in small grains and flax with bromoxynil. The highest yields of barley, oats, and wheat were obtained on plots treated with 4 oz/A of bromoxynil plus 4 oz/A of MCPA. Bromoxynil was effective on many annual broadleaf weeds but not on wild mustard. Dicamba was more effective on wild buckwheat than 2,4-D but not more effective on other common broadleaf weeds. Excellent control of Canada thistle was obtained with post emergence treatments of atrazine plus oil. The most effective treatment was a split application of 2 lb/A plus 1 gallon of crop oil followed in three weeks by another 2 lb./A plus 1 gallon of oil. Flax was more tolerant to atrazine than the small grains and can be used as a rotational crop following the use of atrazine.

SUPPORTED BY: U.S. Dept. of Agriculture

4.0176, FATES OF AGRICULTURAL CHEMICALS IN SOILS

E.M. WHITE, South Dakota State University, Agricultural Experiment Sta., *Brookings, South Dakota* 57006 (SD00518)

OBJECTIVE: To study the fertilizer element, pesticide and herbicide contents in agricultural surface-water runoff; vertical movement in soils of different textures and drainage characteristics; management practices that determine the amount added to surface and groundwater runoff.

APPROACH: Surface water runoff from established plots at Madison, Garden City, Cottonwood, and plots proposed at Presho will be analyzed for fertilizer elements (and other agricultural chemicals if applied) to determine the quantity lost with different management practices and different soils. Additional water samples will be analyzed from areas with other soils when the management practices can be ascertained. Soil profiles will be studied to determine the movement and fate of applied agricultural chemicals.

PROGRESS: This project was initiated July, 1969. Runoff samples were collected from runoff plots at Madison and Garden City for analyses of the plant nutrients. Soils in the plots were also sampled for laboratory analyses to determine the relationship between nutrient levels of the soils and the runoff. Vegetation and soil from the Altamont Prairie were sampled twice this fall to establish the nutrient levels prior to freezing, so sample can be collected in the spring to determine the amount of nutrients which could be lost in snow melt runoff.

SUPPORTED BY: U.S. Dept. of Agriculture

4.0177, BEHAVIOR OF SPECIFIC HERBICIDES IN PLANTS AND SOILS

L.S. JEFFERY, Univ. of Tennessee, Agricultural Experiment Sta., *Knoxville, Tennessee* 37916 (TEN00045)

OBJECTIVE: Determine the effects of climatic and edaphic factors on movement, persistence and toxicity of herbicides in the soil.

APPROACH: For a more detailed explanation, see S-18 (Revised) dated July 1965. Soil columns representating several soil types will be constructed in the laboratory. These columns will be treated with herbicides and then varying amounts of simulated rainfall applied. Bioassays will be conducted to determine the depth to which the herbicides are leached in phytotoxic concentrations. Similar studies will also be conducted under field conditions. Establish the pattern of herbicide dissipation in the soil underfield conditions, field plots will be treated at recommended and higher rates. Plots will be sampled and bioassays conducted. These treatments and samplings will be conducted over a period of several years.

PROGRESS: The past project leader left the University of Tennessee in March and the new project leader arrived in July. No unfinished research was in progress. The only research carried during the specific period pertaining to herbicide residue in soil was a bioassay to determine if any residues of herbicides applied while stubble planting soybeans in wheat remained after soybean harvest. Various rates and combinations of alachlor, amiben, DCPA, linuron, naptalam and paraquat were applied as preemergence herbicides on June 13 and linuron was applied postemergence in September. Soil samples from each plot were placed in the greenhouse in November and bioassayed with crimson clover, lettuce and wheat seedlings. The bioassay results for residues were negative.

SUPPORTED BY: U.S. Dept. of Agriculture

4.0178, DISPOSITION OF PESTICIDES IN THE SOIL

L.F. JOHNSON, Univ. of Tennessee, Agricultural Experiment Sta., *Knoxville, Tennessee* 37916 (TEN00241)

OBJECTIVE: Determine inactivation and loss of pesticides from soil by microbiological degradation for the purpose of identifying primary loss processes, relating these processes to soil properties, and predicting pesticide persistence.

APPROACH: Degradation of pesticides by indigenous populations will be studied in soils. Break down products and the microbial populations primarily responsible will be identified. The effect of soil conditions and ecological factors such as commensalism and antagonism accompanying microbial degradation of pesticides will be investigated. Microbial activity will be modified by suitable treatments in an attempt to alter degradation of pesticides. See S-62 for further details.

PROGRESS: A method for obtaining a suspension of heptachlor granules in isolation media was devised. Growth of 95% of soil bacteria was inhibited by 200 ppm of heptachlor in isolation media. Most of the soil microorganisms resistant to high concentrations of heptachlor were gram negative rods and yeasts. Alfalfa hay and oat straw, finely chopped, were added to soil at rates of 1 and 4% by weight. Heptachlor granules, ground into a powder, were added to residue-amended soils in 250 ml flasks at rates of 20 and 200 ppm. Treated soils were watered and incubated for 8 months. Heptachlor in each flask was extracted with xylene and tested for concentration with a gas chromatograph. More heptachlor was changed to heptachlor epoxide in residue amended soil than in unamended soil. The amount of epoxide present correlated positively with residue amendment concentration. Heptachlor concentration was considerably less in extracts of soils containing alfalfa than in oat straw amended, or unamended soils.

SUPPORTED BY: U.S. Dept. of Agriculture

4.0179, DISPOSITION OF PESTICIDES IN THE SOIL

R.J. LEWIS, Univ. of Tennessee, Agricultural Experiment Sta., *Knoxville, Tennessee* 37916 (TEN00237)

Objective: Determine the inactivation and loss of pesticides from soil by: volatilization; retention and release; nonmicrobiological degradation; for the purpose of identifying primary loss processes, relating these processes to soil properties, and predicting pesticides persistence.

Approach: Well characterized soils, soil separates, clay minerals and other appropriate organic and inorganic adsorbents will be used. Soil system parameters to be evaluated may include pH, temperature, moisture, mineralogical composition, organic matter, exchangeable cations, air movement, sterility, and method of pesticides application. Pesticide parameters may include such variables as formulation, solubility and vapor pressure. Appropriate analytical methods will be selected from among x-ray diffraction; atomic, infrared, visible, and ultra-violet spectroscopy; paper, thin-layer, and gas chromatography; and radioassay. For further details, see S-62.

Progress: Phorate and demeton were adsorbed by Southern Bentonite resulting in an increase in the basal spacings of Ca or Al saturated clay. The observed expansion of clay occured at pesticide concentrations of 0.15 mM per g of clay and greater. Basal spacings of approximately 17A occurring at higher pesticide concentrations could be reduced to 14.5-15.0A by dialysis with distilled water. The thiono isomer of demeton disappeared completely from aqueous systems in two weeks. Compounds that

have been described as the major plant metabolites appeared at the end of one week. These compounds and the thiol isomer persisted for the entire six week testing period. Soil or clay columns retained 0.3-1.0 ug of thiol isomer per g after leaching with approximately four column volumes of distilled water. Very small quantities of an unidentified degradation product of the thiol isomer were eluted from the column in advance of the major elution peak. Moisture status at time of application had little effect on demeton retention but phorate retention was greatest when applied to dry columns. Soil adsorption of the thiol isomer of demeton from equilibrium solutions increased with increasing levels of O.M. and to a lesser extent with increasing clay content. Ion saturation of the exchange complex had little effect on demeton adsorption by soils or clays.

SUPPORTED BY U.S. Dept. of Agriculture

4.0180, METABOLITES OF ENDRIN IN SOILS & CROPS
H.G. ALLBRITTEN, Memphis State University, Graduate School, *Memphis, Tennessee* 38111

The diene pesticide, endrin, is one of the most widely used and toxic chemicals used in the Mid-South area. Only a small percentage of the applied pesticide is accounted for as a residue in soils and crops or is detected in water run-off from these.

We propose to study the degradation and metabolic product of endrin in soils and crops to determine the unaccounted for part of the applied pesticide. To do this we propose to prepare a number of potential metabolites and establish their identities. We will determine the properties of these compounds necessary for their extraction, purification or clean-up and final quantitative determination if present in a soil of crop. We will then extract and quantitatively determine these compounds in samples of soils or crops, and water run-off from these, which have been exposed to the pesticide endrin.

If time permits we will extend the study to other diene pesticides such as dieldrin, heptachlor and chlordane.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.0181, CHEMICAL FALLOW FARMING IN THE SOUTHERN GREAT PLAINS
A.F. WIESE, Southwestern Great Plains Ctr., *Bushland, Texas* 79012 (TEX01340)

OBJECTIVE: Determine the effect of chemical fallow during a wheat- sorghum-fallow rotation on runoff, soil losses, moisture storage, residue conservation, crop yields and other physical microbiological and chemical properties of Pullman silty clay loam soil. Determine factors which may enhance the effectiveness of herbicides on grass weeds under semi-arid conditions and evaluate new herbicides for controlling weeds in continuous sorghum, continuous wheat, wheat-fallow, and wheat- sorghum-fallow rotations. Determine the effect of herbicidal treatment on the water use and weed growth.

APPROACH: A long term experiment will be conducted to determine the effect of chemical fallow on soil moisture storage runoff, crop yield and various physical, chemical and microbiological properties of the soil. Studies will be conducted to locate herbicides for chemical fallow in various cropping systems. Studies will be conducted to determine factors which will enhance the effectiveness of herbicide to grass weeds under semi-arid condition.

PROGRESS: In 1969 the most soil and water loss on dryland runoff plots comparing disking, sweeping, and chemical fallow occurred on the chemical fallow plot in fallow. Residues were low because of a poor sorghum crop in 1968. The next most runoff and soil erosion occurred on the sorghum plots that were sweep plowed. In another chemical fallow study which compared soil moisture from wheat harvested in 1968 to sorghum planting in 1969, chemical fallow plots with heavy irrigated wheat straw stored about 2.5 more inches of soil moisture than disk plots. Preliminary work was conducted to determine if sugar beets could be planted in growing wheat and wheat stubble. We are summarizing data from an old study called Tex B-43. Work on this project could lead to a revolution in tillage and cultivation practices in agriculture. It may eliminate up to 50% of the expense in present tillage practices. It appears that additional water storage could greatly enhance the limited water supply in West Texas.

SUPPORTED BY U.S. Dept. of Agriculture

4.0182, THE LOSS OF HERBICIDES FROM SOIL
R.W. BOVEY, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (0710-04-22(CA))

OBJECTIVE: Determine quantitatively the losses of volatile herbicides from soil to the atmosphere as influenced by soil type, soil manipulation, light, soil moisture, temperature, and wind velocity. Evaluate the potential use of carriers and additives to regulate herbicide loss from soils.

APPROACH: Herbicides and herbicide formulations applied to sandy loam and clay soils will be sampled at intervals up to 24 months after treatment and preserved for herbicide residue analysis. Responses of weeds and other plants will be analyzed concurrently with soil sampling. The amount of herbicide lost from the soil due to such factors as wind, temperature, light, moisture, soil type, degree of mixing in soil, and formulation will be assessed under both laboratory and natural conditions. Herbicide residue content in field and laboratory soil, and in air and dust samples will be quantitatively analyzed by gas chromatographic or other suitable techniques.

PROGRESS: A method was developed of detecting trifluralin vapors in air, sensitive to 8 ppm and which requires less than 5 min per sample. Low volatile oils reduced the volatility of trifluralin in greenhouse studies but neither oils, ultraviolet light inhibitors nor cationic surfactants increased the effectiveness of trifluralin in the field. The volatility of trifluralin was closely related to soil moisture. Nitralin was less volatile than trifluralin. The C-6989 had decreased to about 50 percent of the original amount 3 months after application to a clay or sandy soil and about 10 percent after 6 months. Incorporation increased the persistence. A method of detecting picloram which requires no esterification was developed. The method reduces the time and solvents required. Little picloram is lost from the surface of soils, varying from dry to wet, after one week at wind velocities of 0 to 15 mph. This was true for salt and ester formulations. Ester formulations were much more susceptible to photodecomposition. The reverse was true for leaching.

SUPPORTED BY U.S. Dept. of Agriculture

4.0183, PERSISTENCE AND MODES OF HERBICIDE DISSIPATION UNDER RANGELAND CONDITIONS
C.J. SCIFRES, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (TEX01822)

OBJECTIVE: Determine the various modes of dissipation of herbicides applied for woody plant control. Establish the relative importance of the various modes of herbicide dissipation after their application for woody plant control. Compare the persistence of promising herbicides for woody plant control in rangeland soils, plants, and soil water.

APPROACH: Bioassay and gas chromatographic analysis will be utilized to characterize the residue potential of herbicides applied for control of brush. Herbicide mobility in rangeland soils and soil water and relative rate of herbicide dissipation will be correlated with topography, soil type, rainfall patterns and existing vegetation. Sequential sampling patterns of the vertical vegetation and soil strata will be correlated with rate of relative herbicide movement downslope from the point of application.

PROGRESS: No progress reported this period (New project).

SUPPORTED BY U.S. Dept. of Agriculture

4.0184, MOVEMENT OF INSECTICIDES IN SOIL AND WATER
G.W. THOMAS, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (SWC-024-BELT-10)

OBJECTIVE: Determine the effects of rainfall amount and intensity on the movement of insecticides through soils and in washoff of soil and water; predict the extent of pollution from typical Blackland farming enterprises.

4. PESTICIDES

APPROACH: Three small watersheds at Riesel will be sampled periodically to determine the distribution with depth of DDT, toxaphene, and parathion in the soil. Runoff water, ground water, and eroded sediment will be collected and analyzed for these same substances. Two instrumented sites, at Riesel and at College Station, will be used to determine the rate of pesticide movement relative to water movement in clay soils.

PROGRESS: Three small watersheds in central Texas, which are adjacent to each other and in a rotation of oats, cotton, grain sorghum, are being used to monitor pesticide residues in soil and loss in runoff water and sediment. The only insecticides which have been applied to these watersheds have been toxaphene and DDT. Soil samples taken to a depth of 5 feet contained very little toxaphene at depths below 1 foot. DDT tended to be higher in the surface 6 inches than at any other depth, but appreciable quantities of DDT were found throughout the 5 foot depth in some profiles. Profile samples from waterways were found to contain very little DDT and almost no toxaphene. A sample of silt collected in one waterway contained only 0.06 ppm toxaphene and only 0.052 ppm DDT. Only about 20% of the toxaphene and DDT applied in the past 10 years could be accounted for in the soil profiles. Insecticide residues in runoff waters were not of significant concentrations with respect to pollution problems. In the runoff following one storm the DDT concentration reached 1.0 ppb. No toxaphene was found in any of the water samples. Water samples collected from a seep indicates that DDT is indeed moving through the soil profile but concentrations are very small. When the seep initially began to flow the concentration of DDT was slightly in excess of 1 ppb but quickly decreased to less than 0.2 ppb.

SUPPORTED BY U.S. Dept. of Agriculture

4.0185, MOVEMENT OF HERBICIDES IN SOIL, SURFACE WATER AND UNDERGROUND WATER

A. WIESE, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (SWC-024-BELT-11)

OBJECTIVE: Determine movement and fate of herbicides with irrigation and rainfall in and from West Texas fields, playa lakes, and recharge wells. Conditions that favor herbicide removal in runoff water will be determined.

APPROACH: Runoff water from about 50 fields will be sampled to determine if herbicides are being removed. Ponds and lakes will be treated with herbicides to study movement and breakdown, and a recharge well will be treated with an herbicide to determine herbicide movement and persistence in the underground aquifer. Models will be constructed to determine soil moisture, soil type, slope, and rainfall conditions that favor herbicide removal from fields. Adsorption of herbicides in mud in lake water and Ogallala sand will be determined in the laboratory. A model will be developed to study herbicide movement in Ogallala sand.

PROGRESS: On five fields in West Texas only 14% of applied trifluralin remained in the soil 3 months after application. On one field each, only 20 and 8 percent of propazine and atrazine persisted 1 month after application. Runoff samples from these same fields contained a maximum of 0.04, 0.05, and 0.04 ppm of trifluralin, propazine, and atrazine, respectively. At these concentrations there would be less than 1.2 pounds of active ingredient in 100 acre-inches of runoff. Trifluralin, atrazine, and picloram were applied to soil in small basins at 1, 1, and 1/2 pounds per acre, respectively, which were later flooded. Trifluralin and atrazine did not get into the water, but detectable amounts of picloram were in the water. Trifluralin disappeared from the soil in 2 months of flooding. Soil samples for picloram and atrazine have not been analyzed.

SUPPORTED BY U.S. Dept. of Agriculture

4.0186, WEED CONTROL IN VEGETABLES AND EFFICIENCY OF HERBICIDES IN FIELD SOILS

R.M. MENGES, U.S. Dept. of Agriculture, Fruit Veg. Soil & Water Lab., *Weslaco, Texas* 78596 (0710-03-05)

OBJECTIVE: Study relationship between herbicidal properties and microclimate as regards herbicidal activity, movement, and persistence of herbicides in soils and plants, and plant selectivity to develop practices for weed control in vegetables.

APPROACH: Study techniques of herbicidal application in soils and resulting effects on herbicidal effectiveness, movement and persistence in soil; effects on vegetable growth, composition, and quality; use bioassays and chromatographic assays to determine herbicidal activities and controlled environment to program field climatological differentials affecting herbicidal activities and plant growth.

PROGRESS: In hot wet soils, bensulide and trifluralin incorporated to depths of 1 or 3 inches selectively controlled Amaranthus spp. and barnyardgrass in cabbage plantings. Trifluralin was more effective when deeply incorporated into the soil but bensulide was unaffected by depth of incorporation. Despite rainfall, bensulide CDEC, DCPA, and trifluralin remained within the original zones of incorporation in the soil. Trifluralin persisted longer in soil as depth of incorporation was increased but activity had disappeared in 12 months. Bensulide at 8 lb/A persisted in soil for more than 12 months. Bensulide, incorporated at 1 1/2 inches, selectively controlled common purslane, Palmer amaranth, and barnyardgrass in onion plantings. Irrespective of rainfall, the herbicide performed better with soil incorporation. Bensulide, alone or in combination with nematicides 2-methyl-2(methylthio)propionaldehyde O(methyl carbamoyl)oxime or 1,2-dibromo- chloropropane controlled common purslane and Texas millet in 'El Monte' tomato plantings. Only 2-methyl-2(methylthio)propionaldehyde O- (methylcarbamoyl)oxime reduced rootknot. Tomato yields were increased by treating soil with bensulide plus 1,2-dibromo-chloropropane. Chloroxuron controlled ridgeseed euphorbia, redroot pigweed, and sunflower at 2 lb/A, but in combination with many of the 14 surfactants tested, controlled weeds at 1 lb/A when sprayed at 60 gal/A.

SUPPORTED BY U.S. Dept. of Agriculture

4.0187, SOILS, PESTICIDES, AND THE QUALITY OF WATER

R.L. SMITH, Utah State University, Agricultural Experiment Sta., *Logan, Utah* 84321 (UTA00678)

OBJECTIVE: Identify the properties of pesticides and of soils that controls the extent of movement of pesticides in and through soils. Ascertain the solubility characteristics of pesticides adsorbed on soil particles and hence the effect of suspended soil on the concentrations of pesticides in water.

APPROACH: Adsorption, flow, and thermodynamic properties of a variety of pesticides will be studied in connection with montmorillonitic and kaolinitic types of clays, sand, and complete soil. Specific compounds will be selected to give carboxyl, carbonyl, amine, amide, and double bonded oxygen, sulfur, or phosphorus position that may interact with clay to exchange with cations present in the colloidal complex of soil materials. Thermodynamic properties of systems consisting of various soil materials and water will be studied. Organic pesticides will then be adsorbed onto the soil solids and the thermodynamic properties will again be studied. In this way the change in properties will be evaluated.

PROGRESS: A study of the soil type role and related factors on pesticide movement in surface waters has recently been initiated. Preliminary tests have shown that exchange of phenoxy herbicides is dependent upon pH of soil and water; organic content; concentration of the herbicide. A major effort is being made to define the role of organic matter in this exchange reaction. A major accomplishment of the projects has been the development of a GLC technique capable of routine measurements for concentrations around 0.1 parts per billion picloram. In addition to GLC, fluorescence measurements are simple, highly reproducible and can be performed on considerably more samples in a given amount of time. It will be a valuable analytical and tracer tool. Detailed degradation studies were made on picloram in water under the influence of light, temperature and pH of water. The compound was significantly degraded photochemically and thermochemically. The primary degradation product appears similar in either process and has been tentatively identified as decarboxylated-picloram (product-I). Work is continuing to determine further degradation or stability of product I and its toxicity. Picloram and product I have been separated and purified on alimina columns. Both have demonstrated considerable fluorescence at certain temperatures.

SUPPORTED BY U.S. Dept. of Agriculture

4.0188, TRANSLOCATION AND DEGRADATION OF HERBICIDES IN PLANTS

S.W. BINGHAM, Virginia Polytechnic Institute, Agricultural Experiment Sta., *Blacksburg, Virginia* 24061 (VA-0616062)

OBJECTIVE: Determine translocation and degradation patterns of herbicides in plants and effectiveness for removal from soil and water.

APPROACH: Plant autoradiography and tracer techniques will be used to evaluate translocation and partial metabolism of the herbicide molecule. Chromatographic methods will be used to partially purify and identify degradation products. Quantitative information of herbicide molecule fate will be determined by radioisotopic counting of fractions. For herbicide removal from environment, radioisotopic labeled herbicides absorbed from soil and water will be evaluated in plants and water through counting techniques.

PROGRESS: DCPA- C was root absorbed and translocated slowly in bermudagrass, the level translocated to stolon nodes was too low for root inhibition. Root applications of simazine at concentrations greater than 1 X 10 M inhibited growth of parrot-feather. Chromatographic analysis of exudates from detopped plants showed simazine was translocated primarily undegraded. A correlation was observed between the simazine absorbed and translocated from roots and transpiration. In 2 hours the roots had accumulated the highest level in the plant, after 192 hours, the top of the shoot contained the largest amount per g tissue. Curly pondweed absorbed and translocated simazine- C applied to the roots did not translocate from the exposed portion. Diquat (0.02 ppmw) inhibited growth of emersed parrotfeather. There was no translocation of diquat after foliar or root applications. Dinitrophenol, did not affect uptake of diquat by the roots or cause a translocation of diquat out of the root. Root treatments with 2,4-D (10 M) inhibited growth of parrotfeather and little acropetal movement was evident. When dinitrophenol was applied concomitantly with 2,4-D- C, acropetal movement of radioactivity occurred. Basipetal translocation in the phloem was evident from mature leaves and 2,4-D- C leaked from roots into the nutrient solution. No movement of 2,4-D- C was evident from young leaves.

SUPPORTED BY U.S. Dept. of Agriculture

4.0189, EFFECT OF CHEMICAL ADJUVANTS USED IN FORMULATION ON HERBICIDE PERSISTENCE IN SOILS

L.L. DANIELSON, Virginia Polytechnic Institute, Agricultural Experiment Sta., *Blacksburg, Virginia* 24061 (0710-03-14(GR))

OBJECTIVE: Determine chemical adjuvant effects on herbicide persistence and movement in soils, and means for regulating activity and persistence thru use of adjuvants.

APPROACH: Herbicide classes will include high and low volatility, and water solubility, and different ionic and adsorptive properties. Adjuvant will include nonionic, anionic, and cationic surfactants, phytobland oils, dimethylsulfoxide (DMSO), and other additives. Soils varying in physical and chemical properties will be employed. Herbicides will be applied alone and with different adjuvants directly or as foliar sprays. Spraying and/or incorporation into the soil by drenching or mechanical mixing will be used. Variables will include additive and herbicide concentration, type, application method, treatment time, soil type, irrigation amount and frequency, sterilized and nonsterilized soils. Leaching columns with bioassay of fractions will be used to determine mobility and persistence. Herbicide and adjuvant amounts extracted from soils by plants will be determined by autoradiography. Degradation as influenced by adjuvants will be evaluated by C O(2) evolution, chemical extraction, fractionation, and chromatography. Chromatography will be used to detect residues and purify and identify degradation products. Quantitative information will be obtained.

PROGRESS: The effects of anionic, nonionic, and cationic surfactants, and oil emulsifiers, on herbicide movement in soil were studied using a heavy organic soil as a base for thin layer chromatographic analysis. The order of mobility from greatest to least was dicamba, atrazine, and chlorprophan, respectively, except with cationic Hyamine 1622 where the respective order was atrazine, chlorprophan, and dicamba. Dicamba was affected most consistently by all additives. Precoating the soil with Atlox 109 (a nonionic surfactant) had less effect than adding equivalent amounts to the developing solvent used in the thin layer chromatographic technique. Atrazine and trifluralin persisted longer than dicamba at comparable rates in soil. The activity of dicamba significantly increased by the use of each of the several surfactants. Mixing the surfactants into the soil before applying the herbicides increased their activity.

SUPPORTED BY U.S. Dept. of Agriculture

4.0190, BEHAVIOR OF SPECIFIC HERBICIDES IN PLANTS AND SOILS

O.E. RUD, Virginia Polytechnic Institute, Agricultural Experiment Sta., *Blacksburg, Virginia* 24061 (VA-0626101)

Objective: Determine the effects of herbicides on anatomical and morphological responses, seed germination and growth selected metabolic systems.

Approach: Physiological dormant and active seed will be exposed to varying concentrations of the herbicides 2,4-bis (isopropylamino)-6- methylthio-s-triazine and 3-(n-trifluoromethylphenyl)-1,1- dimethylurea. Pregermination techniques will be imposed on the seed. Measurements will be made of rate and total effects on germination and early development. The responses will be correlated with respiration, enzyme activity, membrane activity and other physiological processes. Physical environmental factors will be studied as they effect phytoxicity of herbicides to seeds. Gross effects of herbicides on fate of seeds in soil will be studied by using radiolabeled seeds as a means of recognizing seedlings.

Progress: Solutions of 3- (M-trifluoromethylphenyl)-1, 1-dimethylurea (fluorometuron) and 2,4 bis (isopropylamino)-6-(methylthio)-s-triazine (prometryne) in water, acetone, or ethanol at concentrations of 90 to 0.0001 ppm have been used to imbibe seeds and evaluate the effect of the herbicide on germination. Seeds that have been included are: Abutilon theophrasti (velvetleaf), Ipomea purpurea (morningglory), Cardus nutons, cotton, and soybeans. Low concentrations of the herbicide on all the species of weeds except Cardus nutons has produced more rapid germination than with seeds imbibed with water. Fluorometuron has produced more stimulation to germination than has prometryne. The crop seeds have not responded to inhibition by the herbicide solutions as have weed seeds. Generally, crop seeds have shown inhibition to germination. Oxygen uptake studies have indicated that with representative crop and weed seeds imbibed in solutions containing herbicides, gas exchange has been related to the germination activity which was not necessarily affected by the herbicide concentration present.

SUPPORTED BY U.S. Dept. of Agriculture

4.0191, DEVELOP WEED CONTROL PRINCIPLES AND PRACTICES FOR HORTICULTURAL CROPS IN THE NORTHWEST

A.G. OGG, Irrigation Ag. Res. & Ex. Ctr., *Prosser, Washington* (0710-03-15)

OBJECTIVE: Devise effective chemical, biological, mechanical, cultural, and combination methods of weed control that avoid or minimize herbicide residues in crops and associated soils.

APPROACH: Conduct comprehensive studies of the ecology and physiology of weeds and crops in competitive situations. Determine the physiological and biochemical effects of herbicides on weeds and crops. Integrate results of these studies to develop new and more economical, safe, and effective methods of weed control for these crops.

PROGRESS: The program was activated in June 1969. An initial survey and evaluation of weed problems in plantings of horticultural crops in the Northwest was conducted. Perennial weeds were found to be a universal problem in croplands of this area. The weeds causing the most concern were Canada thistle, field bindweed, Russian knapweed, quackgrass, Bermudagrass, perennial peppergrass, and hoary cress. Weeds are listed in decreasing order of overall importance. A form letter was sent to over 120 weed researchers in the United States and Canada

requesting information about these weeds. Approximately 50% of the inquiries were answered. Although several of these weeds had been extensively researched, satisfactory control measures in croplands were generally lacking. The results of the survey were used to organize the several phases of the research project. Programs were developed to conduct weed control research in 1970 in the following areas: (1) annual weed control in mint; (2) annual and perennial weed control in fruit tree nurseries; (3) perennial weed control in established asparagus and annual weed control in direct-seeded asparagus; (4) annual weed control in potatoes; (5) perennial weed control in grapes; (6) soil persistence of terbacil in peppermint fields; and (7) the use of soil fumigants for perennial weed control in cropland.

SUPPORTED BY U.S. Dept. of Agriculture

4.0192, SOILS, PESTICIDES AND THE QUALITY OF WATER

H.H. CHENG, Washington State University, Agricultural Experiment Sta., *Pullman, Washington* 99163 (WNP01811)

OBJECTIVE: Identify and characterize the physical-chemical properties of the pesticide-soil water system which are pertinent to pesticide transport through the soil in infiltrating water, and pesticide desorption from eroded soil into surface waters. Identify the principal degradation products and determine the mechanisms and kinetics of pesticide transformations in soil-water systems. Measure pesticide transport through and over soil in the field or in lysimeters, using well characterized initial and boundary conditions.

APPROACH: Laboratory studies will include examination of the adsorption-desorption equilibria of carboxylic acid herbicides (represented by picloram) in relation to chemical properties of representative soils, the transport of picloram by moving water in various soil columns, and the degradation of picloram and organophosphate insecticides as influenced by soil and environmental factors, such as soil pH, organic matter content, moisture level, aeration, and temperature. Particular emphasis will be on the role of organic matter in organophosphates breakdown. Field measurement will be made to evaluate the extent to which pesticide transport can be predicted from information obtained from the chemical, physical, and biological studies done in the laboratory.

PROGRESS: The original project was terminated with our final contribution in the form of a M.S. thesis "Distribution and Transformation of Anhydrous Ammonia in Soil and Effects on Wheat and Pea Foot Rot Fusaria" by R. W. Smiley. Under the revised project, the W- 82 Regional Project Committee has selected two soils from Washington as standards for cooperative study. Bulk quantities of these two soils were collected by horizons, prepared, and distributed to committee members. Physical and chemical properties of the two soils are being characterized and data will be distributed also. Initial research has been on the adsorption and desorption of carboxylic-acid herbicides (2,4-D and picloram) in soils as affected by herbicide concentration, time and temperature of equilibration, and pH of soil. Results indicate that adsorption of herbicide by soil reached equilibrium within 15 minutes of contact. The amount of herbicide adsorbed was dependent on pH of the soil, with increasing adsorption at lower soil pH.

SUPPORTED BY U.S. Dept. of Agriculture

4.0193, TRANSFORMATION, MOVEMENT, DISAPPEARANCE OF PESTICIDES AND RESIDUES IN SOILS

H.H. CHENG, Washington State University, Agricultural Experiment Sta., *Pullman, Washington* 99163 (WNP01858)

OBJECTIVE: Study the behavior and fate of pesticides in soils and the effects of soil properties on pesticides transformation, movement, and disappearance. Improve existing methodology or to develop new methods for the extraction, isolation, detection, and estimation of pesticides and their secomposition products in soils. Examine the conditions for pesticide persistence in soil and to devise means to eliminate this persistence.

APPROACH: As a first step to study efficiency of various extraction and clean-up procedures and, if necessary, to devise new and more proficient procedures. A variety of soils and several types of pesticides will be selected. Subsequently, the mode of pesticide transformation and the effects of the nature and content of clay and silt, organic matter, pH, cation exchange capacities, texture, and related factors on the behavior of pesticides in soils will be examined.

PROGRESS: A field study on the movement of picloram in soil under controlled conditions is in progress. A portable sprinkler irrigator calibrated to provide controlled additions of water uniformly to the test plot has been set up. Movement of picloram in soil of different water content, surface preparation, and slope as affected by rainfall is being studied. Picloram in soil and runoff water will be examined. A gas chromatographic procedure has been tested and proved capable of detecting very small amount of picloram. Extract obtained by using the procedure developed for colorimetric determination of picloram in soil required clean-up before it can be analyzed by gas chromatography. A study on the fate of DCPA in soil has been conducted in an irrigated field at the Othello Research Unit. DCPA was applied at three rates in onion and potato fields in April and June, and soil temperature was monitored throughout growing season. Soil samples were collected periodically for examination of movement and degradation of DCPA. Analysis has been hampered by the lack of a rapid and sensitive method for DCPA detection. Existing methods are time-consuming and have not been tested for DCPA in soil. A rapid infrared spectrometric method was tested but found to lack sensitivity. Modification of a gas chromatographic method is being tested.

SUPPORTED BY U.S. Dept. of Agriculture

4.0194, DEGRADATION OF ORGANOPHOSPHORUS INSECTICIDES IN SOILS

L.W. GETZIN, Washington State University, Agricultural Experiment Sta., *Pullman, Washington* 99163 (WNP01821)

Progress: A heat-labile macromolecular enzyme-like substance in soil which degrades malathion to its monoacid was further purified and characterized. A number of carboxyl ester were hydrolized by the active soil fraction which suggests the substance originally served as an esterase in some biological system. Attempts to demonstrate microbial origin of the malathion-catalyzing factor have been unsuccessful. The addition of partially purified enzyme to soil and its subsequent recovery after more than 8 weeks of incubation indicates the catalyst can exist in a cell-free state in soil. Chemical analyses suggest the enzyme is protected by a polycarbohydrate matrix associated with soil clay adsorption. Dasanit and carbofuran were examined in soil under laboratory conditions. Dasanit was rapidly oxidized to the sulfone which had an initial half-life of greater than 20 weeks at 25 C in a silt loam. Small amounts of Dasanit were also reduced to the sulfide in soil. The persistence of carbofuran varied between soils. The time required for 50% degradation was 8 weeks in a clay loam and greater than 24 weeks in a silt loam and an organic soil. Only small amounts of C from radio-labeled insecticide were expired as CO(2). Carbofuran degraded much faster in alkaline soil than in acid soil.

SUPPORTED BY Washington State Government - Olympia

4.0195, DEGRADATION OF ORGANOPHOSPHORUS INSECTICIDES IN SOIL

L.W. GETZIN, Washington State University, School of Agriculture, *Pullman, Washington* 99163

Objectives: 1) determine the role of biological and non-biological factors in the degradation of organophosphorus insecticides in soil, 2) extract, purify, and characterize heat-labile substances that accelerate insecticide decomposition, 3) investigate the mode of action and kinetics of heat-labile substances that accelerate insecticide decomposition.

Persistence curves will be obtained for insecticides in radiation sterilized, heat-sterilized and non-sterilized soils to determine the relative importance of microorganisms, heat-labile substances and other chemical mechanisms upon the decomposition of insecticides. Attempts will be made to extract, purify and characterize non-viable heat labile substances that accelerate the breakdown of some insecticides. The mode of action and kinetics of a proteinaceous substance which is primarily responsible for the

rapid breakdown of malathion in soil will be investigated. Similar information will be obtained for isolated substances which degrade other insecticides.

Ultimately, this knowledge will contribute towards a greater understanding of why and how insecticides decompose in soil, why certain chemicals are more stable than others and what can be done to improve the efficiency and control the persistence of the insecticides.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.0196, CHEMICAL PROPERTIES OF ORGANO METALLIC FUNGICIDES

V.L. MILLER, Washington State University, Agricultural Experiment Sta., *Pullman, Washington* 99163 (WNP01509)

OBJECTIVE: Investigate the use of organometallic fungicides in control of bulb and turf grass diseases. Investigate phytotoxicity of various organomercury fungicides in the soil.

APPROACH: The work usually consists of preparation of fungicide solutions, determining fungicide concentrations, and various other work needed to back up Dr. Gould's program. Investigate phytoxicity of mercurial fungicides to bulbs, and would investigate permeability of plants, especially bulbs, and translocations of mercurial fungicides in relation to phytotoxicity. Investigation of the breakdown of mercurial fungicides in soil with emphasis on the mechanisms. Application of work previously done here with mercurial fungicides mixed with soil would be extended particularly in relation to turf disease control.

PROGRESS: Busan 72 2-(thiocyanomethylthio) benzothiazole from Buckman Laboratories, Inc. appears to be a very effective fungicide for the control of both Fusarium and Penicillium caused diseases of bulb crops, based on bioassay and preliminary testing. Odor of the Busan 72 may be a problem in some instances. Thiabendazole is one of the fungicides recommended for use to control both Penicillium and Fusarium caused bulb diseases. A test has been developed that is suitable for bulb growers to use to determine the concentration of the thiabendazole in their bulb treating tanks. Thiabendazole reacts with methylmercury compounds at pH 12 to form an insoluble precipitate. The excess methylmercury compound may be determined in the filtrate by the dithizone reaction. The excess methylmercury is related to the concentration of the thiabendazole in the treating tanks by comparing the color developed with dithizone with permanent standards sealed in glass. Bulb growers may find the test useful in controlling the thiabendazole level in their treating tanks.

4.0197, THE BEHAVIOR AND FATE OF DDT AND ZECTRAN IN A FOREST SOIL

S.P. GESSEL, Univ. of Washington, School of Forestry, *Seattle, Washington* 98105 (WO1603)

OBJECTIVE: Determine the movement, chemical change and resulting distribution pattern of DDT and Zectran applied to Douglas fir soils and the effects of environment, land and forest treatments on such reactions.

APPROACH: During the first 2 years of the 3-year project, the investigators will concentrate on field observations, (1) measuring the relationships between the insecticides and the forest soil and environment, and (2) determining the effect of various land and forest treatments on the behavior of the two insecticides. All work, including analysis and interpretation, will be completed the third year.

PROGRESS: No progress reported this period (active project).

SUPPORTED BY U.S. Dept. of Agriculture

4.0198, MICROBIAL DEGRADATION OF PESTICIDES

G.M. BOUSH, Univ. of Wisconsin, School of Agriculture, *Madison, Wisconsin*

A number of present-day widely used pesticides are extremely stable and thus present a major source of environmental contamination. This is especially unfortunate as certain of these same chemicals, correctly used, are important weapons in man's fight against harmful and destructive insect pests. As an example, the chlorinated cyclodiene insecticides resist degradation and thus persist for long periods in soil and water. They also are slow to metabolize in the mammalian system and are little affected by environmental factors such as temperature, moisture or pH. One of the most promising leads in the detoxification of these unwanted contaminants in our ecosystem is by microbial degradation.

This study is designed to investigate the role of microorganisms in the degradation of certain of the more persistent pesticides such as dieldrin, endrin and DDT. In this regard, the following 5 major objectives are planned: (1) Locate, evaluate and identify microorganisms with pesticide-degrading capabilities; (2) Identify metabolites resulting from pesticide degradation; (3) Determine biochemical pathways and enzyme systems involved; (4) Select and develop higher pesticide degrading variants from our most effective isolates; and (5) Investigate the possible role of selected endosymbiotic microflora in the degradaton of pesticides in certain animals.

Pesticide degrading capabilities of all isolates will be determined by incorporation with known quantities of C14 labeled pesticide, followed by extraction, TLC and autoradiography. Bacterial strains ('Pseudomonas spp.' and 'Bacillus spp.') of presently known cyclodiene- degrading abilities will be subjected to mutagenic forces including gamma and ultraviolet radiation, chemomutants and a modified chemostat, together with selection pressure, to develop variants of higher degrading capacities.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.0199, IDENTIFICATION AND DETERMINATION OF PESTICIDE RESIDUES IN SOIL AND RUNOFF AND DRAINAGE WATERS.

G. CHESTERS, Univ. of Wisconsin, Agricultural Experiment Sta., *Madison, Wisconsin* (WIS01342)

No summary has been provided to the Science Information Exchange.

4.0200, SOIL AND PLANT INTERACTIONS WITH PESTICIDES

E.P. LICHTENSTEIN, Univ. of Wisconsin, School of Agriculture, *Madison, Wisconsin*

The metabolism of some insecticides as affected by subcellular components of higher plant tissues and fungi will be further investigated. Purification of enzymes whose activity has been determined, will be attempted. The mechanism of penetration and translocation of pesticides into roots of higher plants will be studied as well as the metabolism of some insecticides within the plant and in vitro. The study of the persistence and metabolism of some insecticides in soils and water will also be continued.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.0201, CONTROL OF PERENNIAL FARM AND RANGELAND WEEDS

H.P. ALLEY, Univ. of Wyoming, Agricultural Experiment Sta., *Laramie, Wyoming* 82071 (WYO15-0069)

OBJECTIVE: Determine potentials and limitations of herbicides and herbicide combinations, in conjunction with mechanical methods, for control of perennial cropland and rangeland weeds. Determine effect of chemical treatments upon soil-plant relationships and effect upon the rangeland ecosystem.

APPROACH: Soil residual characteristics and crop response to chemical treatments determined through actual crop yields and vegetative survey. Atmospheric temperature and soil moisture relationships will be correlated with herbicide response data.

PROGRESS: An area heavily infested with Canada thistle was clean cultivated during the 1968 growing season. In early September various rates of dicamba and dicamba + 2,4-D was applied to the Canada thistle regrowth. Treated areas were crossseeded to several crops in the spring of 1969. Dicamba at 1 and 2 lb/A gave 80 and 93 percent control of Canada thistle, respectively. Dicamba at 1 lb and 2,4-D at 3 lb/A gave a 82 percent reduc-

tion in stand. Phytotoxicity readings indicate that winter wheat is the most tolerant small grain crop followed by corn, oats, spring wheat and barley. Of the broadleaf crops sugar beets was most tolerant followed by alfalfa and dry beans. This study indicates that areas heavily infested with Canada thistle can be cleaned-up and several crops established within eight months after application. Low rates of picolinic acid, 1/4 lb 0 1/2 lb/A remains as the only effective herbicide treatment for effective control of Geyer larkspur. The phenoxy compounds have reduced the stand by only 40 percent after three years of retreatment.

C. ADVERSE EFFECTS ON PLANTS

Includes Nontarget Phytotoxicity, Degenerative, Morphological Effects, and Crop Yield Reduction

4.0202, ADVERSE EFFECTS OF PESTICIDE RESIDUES ON FOOD AND FEED PRODUCTS

R.S. BERGER, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA00613)

OBJECTIVE: Study food and feed products with respect to the location and persistence of pesticide residues in market products, effects of pesticide residues on quality characteristics, and the development of commercial marketing and processing techniques for the detection, removal and/or neutralization of pesticide residue effects.

APPROACH: Products with known histories of production and pesticide applications will be subjected to handling and processing treatments such as brushing, washing, defuzzing, hydrocooling, peeling, freezing, and canning and the effects of these treatments on the reduction or removal of pesticide residues will be determined. Pesticide residue analyses will be made by currently accepted methods. Initially, residues of parathion on peaches, malathion on turnip greens, and toxaphene on southern peas will be studied.

PROGRESS: Mustard, turnip, rape, and collard greens were sprayed on harvest day with malathion and parathion. Replicated samples were hot-water blanched and canned by standard commercial procedures. Residues were determined by G.C. analyses. Comparison of results by F ratios and Duncan's Tests showed only inconsistant effects of vegetable type on residue removal. Per cent removal appeared to depend more upon initial residue level. Heat processing removed all malathion and 75 - 80% of parathion residues. Peaches were field sprayed and laboratory dipped with standard parathion sprays. Highest residues determined were only 3 ppm. No further work with peaches was planned since residues on fruit were so low.

SUPPORTED BY U.S. Dept. of Agriculture

4.0203, PHYTOTOXICITY OF 3-AMINO-1,2,4-TRIAZOLE

M. CARTER, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA-007-6-813)

OBJECTIVE: Study the formation of 3-ATAL in cell-free extracts. Survey the changes in plant protein following treatment with 3(-over AT. Determine if 3-ATAL is incorporated into protein by bean plants.

APPROACH: Cell-Free extracts of bean plants will be prepared by standard procedures of etiolation, centrifugation, incubation and chromatographing. Extracts will be followed by attempts at enzyme purification by gel-filtration and chromatography on DEAE-cellulose. The action of several inhibitors and cofactors will be investigated. Concentrated proteins will be prepared by standard methods and separated by electrophoresis. Following separation and staining the plates will be scanned and the peaks compared. The terminal growth of treated plants will be harvested, extracted, desalted and concentrated by standard methods. Chromatograms will be exposed to X-ray film. Areas of radioactivity will be located and the presence of 3-ATAL detected.

PROGRESS: Amitrole, pyrichor, and dichromate were found to be inhibitors of Beta-carotene synthesis in higher plants. The chlorosis induced by the three herbicides is believed to result from photo- destruction of chlorophyll in the absence of Beta-carotene. Plants grown in the presence of amitrole in the dark form appreciable chlorophyll when exposed to low levels of light but very little chlorophyll at high light intensities. Carotenoid synthesis may represent the site of action for a number of herbicides.

SUPPORTED BY Alabama State Government

4.0204, BEHAVIOR OF SPECIFIC HERBICIDES IN PLANTS AND SOILS

D.E. DAVIS, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA00233)

OBJECTIVE: Determine the effects of climatic and edaphic factors on movement, persistence and toxicity of herbicides in the soil; investigate the absorption, translocation, accumulation, and degradation of herbicides in plants, and determine the effects of herbicides on anatomical and morphological responses, seed germination and growth, and selected metabolic systems.

APPROACH: Plants varying in resistance to each herbicide will be used in all studies and radiolabelled herbicides in absorption, translocation, accumulation, and degradation studies. Amounts absorbed will be determined by radioassay of the plant and of nonabsorbed herbicide and translocation and accumulation by autoradiography. Degradation will be determined by assay for 14(C)(O)(2) in evolved gases and radioassay of chromatographically separable 14(C)-compounds in plant extracts. Herbicide-treated and untreated plants will be exposed to 14(C)(O)(2) in light and dark. Extracts of these plants will be paper-chromatographed and kinds and amounts of 14(C)-compounds determined. In vivo and in vetro effects of each herbicide on P:O ratio and QO(2)(N) of isolated mitochondria will be manometrically determined.

PROGRESS: Ametryne, 2-(ethylamino)-4-(isopropylamino)-6- (methylthio-(S over -)-triazine, and prometone, 2,4-bis(isopropylamino)- 6-methoxy-(S over -)-triazine, were shown to inhibit state 3 respiration of rat liver mitochondria. Prometone inhibition is markedly less than that of either prometryne or ametryne. Inhibition brought about by either ametryne or prometone can, like prometryne inhibition, be relieved with m-Cl-CCP. Various concentrations of an alkanolamine salt of 2,4-D (2,4-dichloro-phenoxyacetic acid) and ametryne were supplied to corn and soybean seedlings in nutrient solutions. Adding 0.01 ppm 2,4-D to solutions containing 0.1 ppm ametryne increased ametryne absorption and plant injury. Absorption of C-ametryne was determined by measuring C per ml of nutrient solution 0, 1, 2, 3, and 4 days after treatment and per gram of fresh weight of roots, shoots and whole plants 1, 2, 3, and 4 days after treatment. In a study of 9 2,4-D concentrations ametryne absorption increased from 50% of the check for 10 M 2,4-D to about 120% for 10 M.

SUPPORTED BY U.S. Dept. of Agriculture

4.0205, FATE AND MECHANISM OF ACTION OF HERBICIDES

D.E. DAVIS, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA-05-0001)

OBJECTIVE: Determine effect of herbicides on carbon fixation, nitrogen metabolism, and activity of certain enzyme respiratory systems. Study degradation of herbicides by susceptible and resistant plants and determine kinds and amounts of metabolites. Determine amounts of herbicide remaining in plants and soils as influenced by various factors. Note: Atrazine will receive primary emphasis in all three objectives.

APPROACH: C-14 labeled CO(2) will be used in carbon fixation studies. Kinds and amounts of C-14 compounds will be determined. Ammonia, protein, and non-protein levels will be determined after various herbicide treatments. In vivo and in vitro effects on mitochondrial respiration will be determined manometrically. C-14 labeled herbicides will be fed resistant and susceptible plants and the radiolabeled materials will subsequently be extracted, separated, radioassayed, and identified. Amounts of herbicides absorbed by plants will be determined chemically and radiochemically. Residues remaining in soils will be determined both by biological and chemical assay.

PROGRESS: Growth regulator-like effects were investigated for ametryne, 2-(ethylamino)-4-(isopropyl-amino)-6-

(methylthio-(s over -)- triazine, atrazine, 2-chloro-4-(ethylamino)-6(isopropylamino)-(s over -)-triazine and prometryne, 2,4-bis(isopropylamino)-6-(methylthio)-(s over -)-triazine. A 10 M atrazine concentration increased both fresh and dry weight of non-green soybean cotyledon callus tissue but higher concentrations were inhibitory. Ametryne and prometryne concentrations from 10 to 10 M were inhibitory. Neither ametryne nor atrazine had any effect on germination of tobacco or lettuce seed in the dark. Atrazine and ametryne were apparently inhibitory or had no effect on rooting of intact black valentine and mung bean coleoptiles but were stimulatory when hypocotyl was decapitated at the cotyledonary node following (s over -)-triazine absorption. Atrazine was inhibitory again in the presence of exogenous IAA. Atrazine concentrations of 10 and 5 x 10 M delayed senescence of corn leaf discs in the dark but this effect was overcome in the presence of kinetin and was not observable when discs were incubated in diffuse light.

SUPPORTED BY Alabama State Government

4.0206, FOREST PRACTICE ALTERNATIVES IN CENTRAL ALABAMA

E.J. HODGKINS, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36[illegible] (ALA-007-0.06)

OBJECTIVE: Scientifically evaluate forest practices in terms of increased productivity of forest land. Determine economic feasibility of applying tested practices to forest lands. Develop recommendations based on research results that have potential of increasing economic value of the forest resource.

APPROACH: Alternative techniques will be developed to seek solutions to problems and field tested. Results will be measured in terms of growth, stocking and quality of the forest following treatments. Comparative costs of alternative treatments will be determined.

PROGRESS: Height growth responses to pre-commercial thinning were found not to be significant, but diameter growth increased more than 50% when soil and roots were not disturbed (significant at 1% level). Measurements will continue for 3 more years. Chemical cultivation of newly established pine plantations (using Atrazine and Simazine) shows significantly better height growth than did mechanical cultivation practices attempted. The use of 2,4-D controlled the weed competition but also apparently injured the pines to such an extent (when applied as a directed spray) to negate the advantage of reduced competition.

SUPPORTED BY Alabama State Government

4.0207, INFLUENCE OF HERBICIDES, FUNGICIDES, & INSECTICIDES ON COTTON GERMINATION & SEEDLING VIGOR

W.C. JOHNSON, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA-03-0020)

OBJECTIVE: Determine the interaction of herbicides, fungicides, and insecticides on cotton seedling growth, the influence of pesticides on susceptibility of cotton to fungi, and the influence of pesticides on fungi.

APPROACH: Field, sterile, and inoculated soils will be treated with selected herbicides, fungicides, and insecticides and planted with cotton. Other variables will be temperature, humidity, and pesticide placement. Data will be obtained on germination, growth and root morphology. Comparison of cotton susceptibility to specific fungi as influenced by environment and pesticides will be made. Reaction of fungi in cultures to pesticides will be studied. Cotton tests will be conducted in growth chamber, greenhouse or temperature controlled tanks; fungal tests will be conducted in the laboratory.

PROGRESS: Results from cotton grown in Hoagland's solution showed that trifluralin and diuron caused a reduction in growth especially at the 1 mg/l level. 1-chloro-2-nitropropane(Lanstan) was phytotoxic at the 10 mg/l level, whereas PCNB (Terrachlor) had no effect on cotton. There were few interactions between diuron and various pesticide combinations. Phorate and disulfoton at the 10 mg/l level tended to decrease the intensity of the effect of trifluralin on cotton. Soil temperatures of 70 F or lower slowed severely the rate of seed germination of cotton. Emergence and initial growth was faster at 80 and 90 F than at 60 or 70 F. Plant response to trifluralin was maximal at 70 and 80 F, those temperatures at which growth was favored. Diuron appeared to have little or no effect on the growth of cotton at any temperature tested when applied at the rate of 1 lb/A. Phorate and disulfoton enhanced the growth of cotton over that of the check especially at the 10 lb/A rate. Effect of trifluralin on cotton was reduced by approximately 25% when phorate or disulfoton were applied at the rate of 10 lb/A in combination with trifluralin. Plant height involved several interactions, but there were fewer interactions affecting dry weight. Prometryne inhibits oxidative phosphorylation of the mitochondria, but does not inhibit their ATPase activity.

SUPPORTED BY U.S. Dept. of Agriculture

4.0208, CONTROLS FOR MAJOR COTTON DISEASES IN SOUTHEASTERN U.S. INCLUDING RESISTANCE

A.J. KAPPELMAN, Auburn University, U.S.D.A. Crops Research Div., *Auburn, Alabama* 36830 (0200-02-02)

OBJECTIVE: Search for higher levels of resistance to fusarium wilt and the wilt-nematode complex; transfer resistance to desirable commercial types; determine mode of inheritance of resistance; cooperate in regional seed and soil fungicide studies.

APPROACH: Using recently developed screening techniques, search existing germ plasm sources for resistance factors; cooperating with breeders transfer and combine resistance in desirable breeding stocks; from seedling response determine the most efficacious materials, combinations of materials, and methods of application for seedling disease control and stand establishment.

PROGRESS: Resistance of 10 lines to the Fusarium wilt-nematode complex was evaluated at two locations. A highly significant location x entry interaction indicated the need for establishment of wilt differentials at each location for comparison purposes. Resistance to Xanthomonas malvacearum in segregating populations of fusarium wilt resistant lines was evaluated. Ten lines resistant to X. malvacearum were comparable to Auburn 56 in wilt resistance and were higher yielding with superior fiber properties. Combined disease resistance was transferred to basic breeding stocks for use by breeders in developing improved varieties. Fungicide applications at planting time resulted in significant increases in plant survival at 3 locations and significant yield increases at one location. The effect of selected fungicides, herbicides, and herbicide-fungicide combinations was evaluated in regard to seedling survival and early growth. Fungicides significantly increased seedling survival but did not significantly affect growth. Use of an incorporated preplant herbicide resulted in significantly reduced plant survival, plant height, and dry weight of plants. Use of a surface pre-emergence herbicide did not significantly affect survival, growth, or plant weight.

4.0209, APPLE INSECTS

C.A. KOUSKOLEKAS, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA-13-0029)

OBJECTIVE: Identify and characterize major arthropod pests of apples. Study biologies of major pests. Develop control measures.

APPROACH: Sample apple insect and mite populations. Identify major pests. Study biologies of major pests in field and laboratory. Initial emphasis on woolly apple aphid and mites. Evaluate effectiveness of current insecticide spray program. Evaluate existing and new insecticides and miticides against major pests to develop efficient and safe control measures.

PROGRESS: All observations were made in an experimental apple orchard. Inadequate bee pollination may have been a contributing limiting factor in the poor fruit set. The currently followed insecticide spray program was effective. No damage by the woolly apple aphid, Eriosoma lanigerum (Hausman), was detected. A moderate late- season infestation of the European red mite, Panonychus ulmi (Koch), developed. The need for establishing criteria governing the initiation of control measures against aphids and mites was given consideration; this was done in an effort to eventually reduce the number of insecticidal applications.

4. PESTICIDES

SUPPORTED BY Alabama State Government

4.0210, WEED CONTROL IN COTTON AND OTHER AGRONOMIC CROPS UNDER IRRIGATED CONDITIONS

H.F. ARLE, U.S. Dept. of Agriculture, Crops Research Division, *Phoenix, Arizona* 85040 (0710-01-04)

OBJECTIVE: Develop chemical, mechanical, and cultural methods for controlling annual and perennial weeds in cotton and other agronomic crops grown in irrigated areas.

APPROACH: Evaluate known herbicides for effectiveness and crop tolerance under greenhouse and irrigated field conditions. Integrate, through field-plot research, the use of herbicides with other production practices. Characterize the effect of herbicide residues on succeeding crops. Study the interaction of herbicides with other chemicals used in producing cotton and other crops.

PROGRESS: The new herbicide, 4-chloro-5-(dimethylamino)-2- alpha,alpha alpha-trifluoro- m-tolyl)-3(2H)-pyridazinone, applied before planting or after emergence of cotton, effectively controlled annual broadleaf and grass weeds without injuring cotton. Combinations of trifluralin with linuron applied before planting cotton, or trifluralin applied before planting followed by layby application of linuron appear effective and safe for control of many species of broadleaf and grass weeds in cotton. Seedling loss was reduced and yield of cotton increased when both trifluralin and diuron were incorporated in soil before planting as compared with incorporation of diuron alone. The insecticides phorate and disulfoton continued to alleviate the adverse effects of trifluralin or nitralin on cotton in continuing research.

SUPPORTED BY U.S. Dept. of Agriculture

4.0211, RESPONSE OF PLANTS AND PLANT COMMUNITIES TO SUSTAINED USE OF HERBICIDES

P.G. BARTELS, Univ. of Arizona, Agricultural Experiment Sta., *Tucson, Arizona* 85721 (ARZT-2020-4159-004)

OBJECTIVE: Study ultrastructural and nucleic acid modifications in plant organelles induced by herbicidal pollutants.

APPROACH: Methods of electron microscopy and nucleic acid biochemistry will be used to study how pollutants modify plant growth and differentiation. Plants will be grown in chamber having regulated light intensities, photoperiods and temperatures. Cell organelles from various tissues will be examined to determine morphological changes induced by herbicides. Also, embryonic and mature cells will be studied to compare effects of pollutants on two different metabolic states of the plant. Since plants respond differently to pollutants when grown in dark, light, or at different temperatures, we plan to modify environment and observe what ultrastructural changes result. DNA and RNA will be isolated from treated and control plants by procedures developed in our laboratory and DNA will be characterized by cesium chloride centrifugation and hybridization studies.

PROGRESS: An ultrastructural examination of 3-amino-1,2,4-triazole (AT) - X Treated wheat seedlings revealed that plastids lacked internal membranes and ribosomes. Our ultracentrifugal study of AT-treated, light grown plants show that 70S, chloroplast ribosomes and Fraction I proteins were absent while cytoplasmic ribosomes, 80S were abundant. Since ribosomes are absent for chloroplasts, we also determined if chloroplast DNA was missing. We isolated and determined the buoyant densities of both nuclear and chloroplast DNA of control wheat seedlings. We found that both nuclear and chloroplast DNA have about the same densities (1.703 2). We isolated the DNA from deformed plastids of AT-treated seedlings and found that no DNA was present. We did find some DNA in the plastid fraction but it had a density of 1.723 which is like bacteria DNA. An ultrastructural examination of this plastid fraction showed many bacteria were present.

SUPPORTED BY U.S. Dept. of Agriculture

4.0212, EFFECTS OF PESTICIDES AND THEIR DEGRADATION PRODUCTS ON PLANTS AND PLANT PATHOGENS

R.L. CALDWELL, Univ. of Arizona, Agricultural Experiment Sta., *Tucson, Arizona* 85721 (ARZT-2014-4166-008)

OBJECTIVE: Determine: 1) effects of pesticides on soil plant pathogens, 2) degradation products of pesticides and rate of degradation by sunlight, chemical and biological degradation, 3) effects of pesticides on plants, both infected and non-infected, 4) synergistic effects of fungicides, insecticides and defoliants, with respect to objectives 1 and 3, and 5) effects of degradation products of objective 2 against common soil plant pathogens.

APPROACH: 1) Initially, pure culture techniques will be used for bioassay procedures, this will be followed by pesticide applications to autoclaved/nonautoclaved soil, both virgin desert and cultivated, and population trends noted; 2) decomposition will be determined by radioactive tracers and residue analysis, sterile/nonsterile soil and pH variation will be used to determine biological and chemical degradation, 3) pesticides will be applied to inoculated/noninoculated plants, visual effects will be noted, metabolic effects will be noted by extraction of plant chemical types, 4) as stated in approaches 1 and 3, 5) degradation products will be treated as in approach 1. Pesticide and pathogens used will be those of major concern in the southwest, such as: PCNB, zineb, nemagon, karmex, treflan, prometryne, aminotriazole, DEF, chlorinated hydrocarbons, and organophosphates, Rhizoctonia solani, Verticillium albo-atrum, Phymatotrichum omnivorum, Pythium sp., Phytophthora sp. and Thielaviopsis sp.

PROGRESS: This project was funded effective 1 July 69 and staffed 1 Aug 69. Initially, samples of native and cultivated soil were assayed for fungi and bacteria present; these were identified as to genus only. To date we have determined the appropriate levels and methods of application of Rhizoctonia solani to cotton plants (Deltapine). The application amounts of a herbicide (Treflan) have been determined and an experiment is in progress relating to the effect of Treflan, Rhizoctonia, PCNB alone and in combination, on cotton. All herbicides (4), and insecticides (2) to be used have been screened (filter paper bioassay) for fungitoxicity, no observable effects were noted up to 1,000 ppm. We are in progress of screening combinations of pesticides to determine any fungitoxicity.

SUPPORTED BY U.S. Dept. of Agriculture

4.0213, INSECT PESTS OF ARIZONA VEGETABLE CROPS

P.D. GERHARDT, Univ. of Arizona, Agricultural Experiment Sta., *Tucson, Arizona* 85721 (ARZT-0206-4161-142)

OBJECTIVE: Develop information on the biology and control of insect pests of commercially grown vegetable crops in Arizona. Particular reference to dosage rates, timing and application methods and how these affect the pesticide residues on these vegetable crops.

APPROACH: Control evaluation of candidate pesticides will be conducted, considering dosage rates, formulations, timing and method of application together with resulting pesticide residues at harvest time. Most important insect problems, namely the lepidopterous larvae occuring on vegetables, will be considered first. This will involve the use of replicated field plots on the University farms and in commercial fields where applicable. Where it is felt necessary the biology of these plots will be further investigated.

PROGRESS: Three formulations of Bacillus thuringiensis, two dusts and a wettable powder were compared with 2.5% BTB - 2% Parathion dust for the control of cabbage looper and beet armyworm larvae on fall head lettuce. Best control was with the wettable formulation applied as a spray three times. No difference was found between the two dust formulations and all were equally as effective as the BTB - Parathion dust formulation. Red La Soda variety of potato plants were treated with six different insecticides for the control of green peach aphids and potato psyllids. Thimet was applied as a granular formulation at planting time. The other five were applied twice during the growing season as sprays. Lannate 90% W.D. gave the best aphid and psyllid control and outyielded all other treatments. Another treatment was aluminum foil placed on top of the seed bed as the plants began emerging. Early in the season plants in these beds had practically no aphids or psyllids. Later on a few aphids and psyllids were present as the plants became larger and shaded the foil. Dust formulations of five pesticides were applied to the ears of sweet corn as a substitute for DDT in the control of corn ear worm. Lannate 2% dust was the most effective material. Desert flea beetle control on

seedling corn, normally controlled with DDT required three applications of other insecticides. Diazinon 14G and Lanadrin 15G were most effective. Golden Acre yellows resistant cabbage was treated four times with six different pesticides or combinations.

SUPPORTED BY Arizona State Government

4.0214. THE INFLUENCE OF CULTURAL PRACTICE COMBINATIONS ON THE YIELD AND QUALITY OF COTTON

R. FORD, Univ. of Arkansas, Agricultural Experiment Sta., *Fayetteville, Arkansas* 72701 (ARK00413)

OBJECTIVE: Measure influence of combining currently recommended cultural practices upon the yield and quality of cotton produced. Find ways of increasing the efficiency of cotton production with emphasis on acceptable yields under a shortened land use time and on higher yields utilizing the full growing season. Develop better methods of utilizing winter legumes such as hairy vetch and crimson clover with emphasis on cotton planting practices. Determine what constitutes a 'stand' of cotton under different fertility levels and dates of planting. Measure the effects of varying cultural practice combinations on quality of lint produced.

APPROACH: Various cultural practices and combinations of cultural practices have been tested under this project for the past five years. Three fertilizer rates and three stand spacings have been tested together for four years. Three stand spacings and three dates of planting have been tested together for four years. These two tests were conducted at Marianna. The effect of skips on yields was also tested at the same location. Dates of planting ranging from April 15th to June 1st have been compared for two years. Single plant spacings of various widths have been subjected to several thinning dates for two years. These tests were grown at Keiser.

PROGRESS: Major emphasis in 1968 was given to the third and final year of an effort to develop ways of measuring insecticide phytotoxicity to plants. Early and late dates of planting with and without irrigation were coupled with high and low fertilizer rates and two varieties as agronomic variables imposed on six insecticides. These represented the hydrocarbons, the phosphates, and the carbamates. Measurements taken were plant growth rates, blooming rates, bloom shed percentages, boll maturation periods, yield and fiber properties. Irrigation or high fertilization, either or both, increased fiber length, decreased micronaire, decreased germination of resulting seed, and lengthened boll maturation periods. The hydrocarbons slightly increased the rate of plant growth, decreased shedding, and increased yields in two of the three years, including 1968. The phosphates tended to slow fruiting rate and lengthen boll maturation periods but did not reduce yields.

SUPPORTED BY U.S. Dept. of Agriculture

4.0215. BEHAVIOR OF SPECIFIC HERBICIDES IN PLANTS AND SOILS

R.E. FRANS, Univ. of Arkansas, Agricultural Experiment Sta., *Fayetteville, Arkansas* 72701 (ARK00550)

OBJECTIVE: Determine the effects of herbicides on anatomical and morphological responses, seed germination and growth, and selected metabolic systems.

APPROACH: Inhibitory responses of plants grown in nutrient solutions to which varying concentrations of the herbicides are added will be interpreted by mathematical growth expressions. Partial characterization of possible reactive sites or mechanisms will be determined by introducing compounds in mixture, competetively inhibiting or interfering with toxicity of the herbicide.

PROGRESS: Radioautographs showed that root uptake of C-methanearsonic acid (MAA- C) by johnsongrass from nutrient solution was rapid and translocation into all portions of the plant occurred within 4 hr after treatment. Basipetal and acropetal translocation of foliar and stem-applied MAA- C occurred in both johnsongrass and cotton, indicating that movement of the herbicide probably occurs in both phloem and xylem tissue. Methanol extracts of MAA- C may complex with either a sugar or organic acid or both. An MAA metabolite, with a positive reaction of ninhydrin, was present in the cotton fraction, suggesting that the metabolit may be a combination of the MAA molecule with histidine or one of its analogues. Spectrophotometric determination showed a build-up of amino acids in MAA treated johnsongrass but not in cotton. The increased levels of amino acids in johnsongrass suggest that the MAA metabolite may be blocking a protein synthesis pathway. The effect of 2,3,5-trichloro-4-pyridinol (pyrichlor), as well as carbonyl cyanide m-chlorophenyl hydrazone, 2,4-dichlorophenol, and oligomycin, on oxygen uptake and oxidative phosphorylation was investigated with mitochondria isolated from hypotocyls of etiolated soybeans. Pyrichlor inhibited both coupled and uncoupled reactions. This suggests that pyrichlor either acts on a nonphosphorylating intermediate close to the electron carrier chain or with a component of the electron carrier chain, or both.

SUPPORTED BY U.S. Dept. of Agriculture

4.0216. STORED GRAIN AND CEREAL PRODUCTS INSECT CONTROL BY METHODS LEAVING MINIMUM OF PESTICIDE RESIDUE

F.D. MINER, Univ. of Arkansas, Agricultural Experiment Sta., *Fayetteville, Arkansas* 72701 (ARK00648)

OBJECTIVE: Investigate traps as a means of control of insects of stored grains and cereal products.

APPROACH: Develop methods of trapping larval and/or adult stages. Effectiveness of traps may be enhanced through various attractants, and value increased through toxicants or sterilants in combination with attractants. Evaluation of trapping as an adjunct to control will be undertaken under field conditions in conjunction with other control measures. Trapping devices and procedures will be evaluated as aids in locating sources of infestation.

PROGRESS: Cryptolestes turcicus was found to be attracted to sorghum grain infested with numerous species including its own, as determined by olfactometer tests using streams of air drawn through the grain. The insects were also attracted to pure cultures of their own species. They were not attracted to dis-infested grain or to pure cultures of other stored grain species. A stream of air was drawn through infested grain and then through a solid $CO(2)$ condenser. The condensate in small quantities was attractive to C. turcicus in an olfactometer and as a bait on a sticky-board trap. These results may contribute to eventual control of stored grain pests without insecticides.

SUPPORTED BY U.S. Dept. of Agriculture

4.0217. EFFECTS OF HERBICIDES ON QUALITY AND CHEMICAL COMPOSITION OF FRESH AND PROCESSED VEGETABLES

W.A. SISTRUNK, Univ. of Arkansas, Agricultural Experiment Sta., *Fayetteville, Arkansas* 72701 (ARK00634)

OBJECTIVE: Determine the effect of herbicides on color, size, shape and appearance of raw vegetables; color, texture and flavor of the canned and frozen vegetables by both subjective and objective tests; chemical composition of the vegetables, and changes in quality during storage of canned vegetables, including tinplate corrosion.

APPROACH: Various herbicides will be applied at optimum and excessive rates to tomatoes, snapbeans and sweet potatoes grown in replicated plots. These vegetables will be harvested at optimum maturity; the raw product graded into sizes and/or color, and processed according to standard methods of washing, peeling, blanching, retorting or freezing, and stored for later analysis. Both canned and frozen samples will be analyzed for various constituents in order to define quality as to color, texture, flavor and acceptance by the consumer.

PROGRESS: TOMATOES: The effects of various methods, rates, and application of diphenamid on quality was not well defined. Hand-weeded plots and diphenamid at 2 lb/A pre-emergence produced slightly better color than the other treatments. SPINACH: The control plots produced spinach that was tougher in the canned products than the cycloate. The spinach treated with cycloate appeared to be slightly greener to a taste panel but the Hunter CDM did not detect a difference. CUCUMBERS: In brined cucumbers there was no effect of herbicides on the color,

firmness, or bloating of the brine stock. There was injury to the plants and a decrease in yield in both tomatoes and spinach where quality differences were indicated.

SUPPORTED BY U.S. Dept. of Agriculture

4.0218, WEED CONTROL IN HORTICULTURAL CROPS
R.E. TALBERT, Univ. of Arkansas, Agricultural Experiment Sta., *Fayetteville, Arkansas* 72701 (ARK00605)

OBJECTIVE: Develop integrated systems of weed control in horticultural crops for the upper Midsouth region. Assess the selective properties of various herbicides and determine the factors influencing selectivity. Determine the effects of intensive herbicide usage in horticultural crops in relation to herbicide residues, weed ecology and product quality.

APPROACH: Replicated field studies comparing various systems of weed control will be established. Crop tolerance to herbicides and weed control edificacy will be measured under a variety of conditions in field and greenhouse studies. The residual activity of herbicide treatments will be monitored using chemical and biological assays. Effects of herbicide usage on ecological changes in vegetation and crop product quality will be observed.

PROGRESS: In some cases, mixtures of herbicides gave increased selective weed control over the single components including diphenamid plus methyl ester of amiben on direct-seeded tomatoes, DCPA plus linuron on Irish potatoes, alachlor plus linuron on snapbeans, DCPA plus chlorpropham and dinoseb plus diphenamid on southern peas, and sesone DCPA on strawberries. However, mixtures involving the methyl ester of amiben or dinoseb were not safely used in cucurbits. Promising new compounds were C-6989 on southern peas and strawberries, alachlor on Irish potatoes, transplanted tomatoes, snapbeans, southern peas, and strawberries, and C-6313 on Irish potatoes. Replanting cucumbers following a preemergence application of nitralin was hazardous for at least 1 month. Strawberries were injured by chloroxuron during hot, dry conditions and by C-6989 during the bloom stage. Up to 3X rates of nitrofen applied to greens caused considerable chlorosis, but there were no significant effects on the yield or processing quality of greens. Weed control was improved during the second year of herbicide application to orchards. Although terbacil has more postemergence activity on weeds, it is more hazardous to fruit trees than other herbicides. Incorporation of simazine reduced its activity. Herbicidal phytotoxicity to young trees was reduced by increasing the fertility level. Pear root stocks showed little tolerance to herbicides.

SUPPORTED BY U.S. Dept. of Agriculture

4.0219, INSECTICIDAL CONTROL OF VEGETABLE INSECTS
W.D. WYLIE, Univ. of Arkansas, Agricultural Experiment Sta., *Fayetteville, Arkansas* 72701 (ARK00638)

OBJECTIVE: Provide recommedations for insecticidal control of vegetable insects; samples for residue analyses and/or taste tests; and conduct investigations of residue decay and initiate petitions for usage.

APPROACH: Usual methods of laboratory and field plot testing will be followed. Procedures for collecting and handling samples for residue analyses or taste tests are generally established. Details of procedures will vary from one situation to another.

PROGRESS: The use of adjuvants with Thuricide did not improve control of cabbage loopers on green crops. Blackstrap molasses had no effect while pinoline decreased effectiveness of Thuricide. Lannate caused damage to greens, especially turnips, even at dosages as low as 0.5 lbs. per acre. A regular dust was only slightly less phytotoxic than sprays but 'safened' dusts caused very little plant damage. Methyl parathion was much more phytotoxic than ethyl parathion. Plant damage was much more severe when sprays were applied to plants wet with dew. Phytoxicity was somewhat higher as emulsifiable concentrates increased in pounds active ingredient per gallon. TDE at 1-1/2 lbs. acre was only slightly less effective than 3 lbs. for bollworm control on tomatoes. Methyl parathion gave as good control as TDE but endosulfan, carbaryl, diazinon and dimethoate were less effective.

SUPPORTED BY U.S. Dept. of Agriculture

4.0220, DEVELOPMENT OF SAFE & EFFECTIVE MATERIALS FOR MANAGEMENT OF WESTERN FOREST INSECT POPULATIONS
D.C. SCHMIEGE, U.S. Dept. of Agriculture, Pac. Sw. For. & Rg. Expt. Sta., *Berkeley, California* (PSW2203)

OBJECTIVE: Develop safe, selective, nonpersistent, and effective materials and techniques to manage forest insect populations to protect the forest environment of the Western United States.

APPROACH: Screening and bioassay of candidate chemicals and formulations for evaluation, selection, and characterization of those most efficient for control of specific pest insects; chemistry and toxicology of selected materials, including study of modes of action and molecular manipulation to optimize control effects; and penetration, translocation, and metabolism of chemicals on and in forest trees to develop efficient foliar systemic treatments.

PROGRESS: Research continues to develop effective, specific, nonpersistent, and safe insect control treatments for serious forest insect pests. In 1969, a pilot test of Zectran completed a 5-year program of testing and evaluating a new treatment for the spruce budworm to replace DDT. A laboratory screening program evaluated an array of insecticides against the Douglas-fir tussock moth, the larch casebearer, the fall cankerworm, the California oakworm, and the orange tortrix. Alternatives to conventional insecticides were investigated. When administered to spruce budworm larvae in dosages far below those causing cholinesterase inhibition, Lannate produces a number of effects resembling those of juvenile hormone: delayed pupation, increased rate of weight gain, and increased incidence of pupal abnormalities. External and internal anatomy of spruce budworm larvae were investigated in detail to evaluate insecticide action. Particular emphasis was placed on impingement and penetration phenomena in and around the setae using radioactive Zectran. Laser holography was used to study the characteristics and behavior of insecticide aerosols. It allowed direct 3-dimensional stop-action study of spray particles as they impinged onto the western spruce budworm larvae and their silk webbing.

SUPPORTED BY U.S. Dept. of Agriculture

4.0221, BIOLOGICAL CONTROL OF HELIOTHIS ZEA ATTACKING COTTON
R. VANDENBOSCH, Univ. of California, Agricultural Experiment Sta., *Berkeley, California* 94720 (CA-B0-BIC-2292-H)

OBJECTIVE: Parasitic and predatory species affecting H. zea in California cotton fields, biology, ecology, phenology, distribution, nature of attack and total and relative efficacy of the natural enemies, cultural and ecological practices and selective chemical and microbial controls to augment biological control, mass release of entomophagous arthropods, introducing exotic natural enemies to supplement the native complex affecting H. zea.

APPROACH: Rearing of field collected material, exposure of lab reared H. zea and observation. The efficacy of the several natural enemies will be determined from cage and field studies and use of exclusion techniques. Bionomical studies will be made. Effects of chemical and microbial control agents on the beneficial species will be measured. Selective artificial controls will be sought and perfected. Mass release of entomophagous forms will be analyzed.

PROGRESS: An experiment in bollworm control demonstrated that intensive use of Methyl parathion and carbaryl caused a substantial reduction in cotton yield, apparently because of adverse effect on plant physiology. Reduced yield occurred even where bollworm infestations were severely reduced. The same experiment clearly demonstrated that cotton can withstand extremely high bollworm populations if predators occur in the fields. The predators destroy the bulk of the bollworms before they reach the late (damaging) instars. Cage studies of Hyposoter exiguae, a parasite of H. zea larvae, produced little useful information. Two factors adversely affected the experiments: (1) poor

survival of H. zea eggs and larvae obtained from a commercial insectary and (2) a lack of vigor in the insectary produced stock of H. exiguae used in the study. Interestingly, a field derived stock of the parasite, showed much greater vigor and fecundity and will be used in the 1970 studies.

SUPPORTED BY U.S. Dept. of Agriculture

4.0222, APPLICATION PRINCIPLES AND DESIGN REQUIREMENTS FOR WEED CONTROL EQUIPMENT

N.B. AKESSON, Univ. of California, Agricultural Experiment Sta., *Davis, California* 95616 (CA-D0-AER-1971-H)

OBJECTIVE: Improve or develop methods and associated equipment for weed control through study of mechanical, chemical, thermodynamic, and other principles.

APPROACH: Investigate mechanical cultivation; flame weeding; use of pre-emergence herbicides as affected by soil and incorporation and irrigation techniques; effects of chemical formulation, coverage, retention, and plant surface differences on foliage applied materials; evaluate spray-producing orifices to improve distribution and drop size control; methods of inhibiting germination of weed seeds in narrow band of soil immediately prior to planting; chemical and cover crop weed control for non-cultivation practices in orchard and vine crops; control undesirable plant species in such areas as range and forest lands; use mulches for general row crop weed control; and minimize toxic soil residues.

PROGRESS: A major effort was made this past season to establish correlations between propanil applications on rice and symptoms and damage to other susceptible crops grown in the area of the rice. Air sampling and test plant analysis indicates the pattern of air transport of the herbicide propanil under specific conditions. Significant reductions in small drop portions of spray produced by the Microfoil boom (AmChem Co.) and also a device developed here in the Department (called the L T N, low turbulence nozzle) point the way to reducing amounts of spray that would be susceptible to aerial transport. Mounted on the helicopter, these nozzles produced less drift than the usual ground rig with medium atomization nozzles. Limitation due to large median drops produced must be overcome, but there is evidence that this may be done.

SUPPORTED BY U.S. Dept. of Agriculture

4.0223, FUNDAMENTAL BIOCHEMICAL AND BIOPHYSICAL MECHANISMS INVOLVED IN HERBICIDAL ACTION

R.M. ASHTON, Univ. of California, Agricultural Experiment Sta., *Davis, California* 95616 (CA-D-ABO-2054-RR)

OBJECTIVE: California will study the comparative effects of treatments on proteolytic enzymes and protein synthesis and degradation.

PROGRESS: The herbicides 2,6-dichlorobenzonitril (dichlobenil), 7- oxabicyclo-(2.2.1) heptane-2,3-dicarboxylic acid (endothall), and 3,5- dibromo-4-hydroxybenzonitrile (bromoyxnil) were examined for their influence on the activity and synthesis of proteolytic enzyme(s) in the cotyledons of squash (Cucurbita maxima Duchesne) seedlings. None of these herbicides affected the activity per se of the isolated proteolytic enzyme(s). The presence of the herbicides in the culture solution during germination caused different effects on the development of the proteolytic activity in the cotyledons for each of the three herbicides. Dichlobenil reduced the development of the activity in both the excised cotyledons and the cotyledons of intact embryos. This inhibition was overcome in part by the addition of benzyladenine to the culture solution. The inhibition of hormone synthesis or export by the embryonic axis caused by dichlobenil could explain the observed results. Endothall inhibited the development of the proteolytic activity in the cotyledons of the intact embryo treatment but had little effect on the excised cotyledons. Benzyladenine did not reverse this inhibition. The effect of endothall resembled the inhibition caused by actinomycin D, possibly indicating that endothall interfered with ribonucleic acid metabolism. Bromoxynil inhibited the proteolytic enzyme(s) development in the cotyledons of intact embryos but not in the excised cotyledons. This inhibition was partly overcome by benzyladenine. These results suggest that bromoxynil not only interferes with the hormonal control mechanism but also proteinase synthesis.

SUPPORTED BY U.S. Dept. of Agriculture

4.0224, RESPONSE OF PLANTS AND PLANT COMMUNITIES TO SUSTAINED USE OF HERBICIDES

D.E. BAYER, Univ. of California, Agricultural Experiment Sta., *Davis, California* 95616 (CA-D0-ABO-2566-RR)

OBJECTIVE: Determine effects of repetitive application or persistent pollutional levels of herbicides on the structure, chemical composition, and function of individual species of the plant community.

APPROACH: Study structural modification of plant organelles caused by herbicides and determine localization and distribution at the cellular and subcellular level. The effects of selected herbicides upon the mobilization of seed storage proteins during germination will be studied to determine the differences in mobilization of these food reserves. This information will be used to help evaluate contamination of our environment by herbicides and to predict shifts in species composition.

PROGRESS: Atmosphere and biological sampling during airplane application of propanil showed that particles of propanil drifted in excess of 20 miles. These particles were less than 50 microns in size but were still of sufficient volume to produce typical propanil symptoms on French prune trees. Electron microscopic examination appears to suggest the only cell organelle to be affected was the chloroplast. Physiological studies indicate the French prune tree is not capable of metabolizing propanil to nontoxic compounds rapid enough to prevent symptoms from forming with injury to the chloroplasts that come into contact with the herbicide.

SUPPORTED BY U.S. Dept. of Agriculture

4.0225, COMPARATIVE BIOCHEMISTRY OF HERBICIDES

P.A. CASTELFRANCO, Univ. of California, Agricultural Experiment Sta., *Davis, California* 95616 (CA-D0-ABO-1975-H)

OBJECTIVE: Develop an understanding of the interactions between various herbicide molecules and the biochemical systems of plants, animals or micro-organisms.

APPROACH: The widespread use of agricultural chemicals, including herbicides, has broad implications with respect to both human health, and agricultural production. A thorough understanding of the biochemical properties of these compounds is therefore extremely important. The fundamental biochemical properties of phytotoxic compounds will be investigated. In vivo work with higher plants and in vitro work with enzyme systems derived from plant, animal and bacterial sources is anticipated; the experimental procedures, in general, will be those of enzyme chemistry and qualitative organic analysis.

PROGRESS: Aged potato tuber slices incubated with C labeled choline, enthanalamine, methionine, serine, and acetate showed that the incorporation of radioactivity into the lipid fraction increased with the length of time the slices had been aged. This incorporation was shown to be true lipid synthesis. An enhanced incorporation of labeled choline mainly was due to increased uptake while enhanced incorporation of labeled acetate resulted from the development of a fatty acid synthetase system during aging. In the case of enthanalamine, both its uptake and its relative incorporation into the lipid fraction increased. The major compound formed from choline was lecithin and from ethanalamine was phosphatedyl-ethanalamine and a small amount of lecithin. The labeled phospholipids were found exclusively in the microsomes up to 8-10 hours of aging while older slices showed some labeling in mitochondria suggesting that slicing induces immediate synthesis of microsomal (endoplasmic reticulum) membrane bound ATPases. Although complete separation has not yet been achieved, it appears that 3 membrane-bound ATPases are present. Histochemical and electromicroscope studies on the intracellular localization of ATPases show a very high concentration in the nucleoli of root cells and a definite activity at the plasmolemma of the oat root cells.

4. PESTICIDES

SUPPORTED BY U.S. Dept. of Agriculture

4.0226, MARKET QUALITY OF TABLE GRAPES AS INFLUENCED BY CHEMICALS APPLIED FOR WEED, PEST AND DISEASE CONTROL

K.E. NELSON, Univ. of California, Agricultural Experiment Sta., *Davis, California* 95616 (CA-D0-VIT-1747-MH)

OBJECTIVE: Determine the effect of new chemicals on the appearance, texture and flavor of the fruit as well as the levels of residue remaining in the product.

APPROACH: Many new chemicals (some highly toxic) have been found effective as herbicides, pesticides, fungicides and growth regulators to improve the market quality of table grapes. The possibility of prolonging the storage life of table grapes by the use of modified atmosphere appears very promising, particularly in the light of the new fungicide dibromotetrachloroethane which is effective as it volatilizes from a solid state within the package. High carbon dioxide levels not only depress the rate of respiration of the fruit, but also depress the rate of growth of decay organisms. These factors together indicate a strong possibility that grapes can be enclosed in a relatively tight container thereby minimizing water loss from the fruit, yet decay can be controlled for several months.

PROGRESS: Sulfur dioxide is the only feasible material available as a fumigant to control decay of table grapes during handling, storage and transit. Though an excellent fugicide, it does cause chemical injury to the fruit that is accumulative with concentration and time of exposure. Needed is more exact information on the concentration-time exposure that offers the best compromise between adequate decay control and chemical injury within acceptable limits. Such information is necessary to develop a fumigation system whereby sulfur dioxide is generated from a source within the closed container to first, (1) surface sterilize the fruit immediately after packing and during precooling, then (2) contain infections in field-infected berries so that the decay does not spread during storage and/or transit. Critically controlled concentrations of sulfur dioxide in 'open' systems have shown that 16 ppm of sulfur dioxide for 24 hours in saturated air while the temperature is lowered from 25 to 5 C will effectively surface sterilize the fruit with minimal injury. To contain field infections during storage at 0 C about 8 ppm of sulfur dioxide is required. Higher concentrations are required at higher temperatures with correspondingly more injury.

SUPPORTED BY U.S. Dept. of Agriculture

4.0227, WEED CONTROL IN AGRONOMIC CROPS

R.F. NORRIS, Univ. of California, Agricultural Experiment Sta., *Davis, California* 95616 (CA-D0-ABO-1901-H)

OBJECTIVE: Develop satisfactory programs of weed control for crops other than cotton. Study influence of environmental factors on effectiveness of herbicides used in field crop situations; physiology and biochemistry of herbicidal action from a fundamental standpoint.

APPROACH: Evaluate most promising selective herbicide-agronomic crop combinations in the field, greenhouse and laboratory. Soil incorporation of herbicides will be emphasized. Fundamental studies include the influence of environmental factors (temperature, relative humidity, spray additives, etc.) upon foilar penetration and translocation, herbicide and surfactant interactions, distributional and metabolic fate of radio-labeled triazine herbicides, barban, dalapon, etc., and herbicide residues in plants and soils.

PROGRESS: Triallate (Avadex BW) gave excellent wild oat control in barley, resulting in yield increases in excess of 400 lb/A. Residue information is being obtained and a recommendation for this chemical should be possible in the 1970 season. Wheat showed less tolerance to this chemical than barley. Terbacil (Sinbar) has shown excellent control of general annual winter weeds and summer annual grasses in alfalfa. RH-315 continues to look promising in alfalfa and ladino clover fields infested with grass weeds. A program has been initiated to find better means of controlling dodder in alfalfa, with generally disappointing results. Herbicide testing in dry beans (lima, kidney and blackeye) is being increased, with special emphasis placed on controlling weed species in the Solanaceae. Logarithmic screening revealed several new chemicals that show considerable promise, with S- 6115 being the most outstanding. S-6115 has also given excellent week control in corn, at as low as 0.5 lb/A applied preplant incorporated. Extensive testing of herbicides for use in sugar beets has continued, with CP-52223 showing potential as a preplant incorporated herbicide. Phenmedipham (Bethanal) gave excellent weed control applied post- emergence during the winter and early spring, but less weed control and more crop injury occurred when applied during May and June.

SUPPORTED BY U.S. Dept. of Agriculture

4.0228, EXTENDING THE MARKET LIFE OF CALIFORNIA CITRUS FRUITS IN FOREIGN MARKETS

G.L. RYGG, U.S. Dept. of Agriculture, Market Quality Research Div., *Pomona, California* 91769 (HC-48)

OBJECTIVE: Relate market quality and chemical residues of U.S.- grown citrus fruits in overseas markets to condition at origin, pretransit, in-transit and destination handling, treatments, containers, and commodity temperature.

APPROACH: Determine decay, deterioration, chemical residues, and other market quality factors in test shipments of citrus fruits upon arrival at overseas ports, or arrival at terminal wholesale markets, and often actual or simulated handling at wholesale and retail markets. These evaluations will be related to product maturity and quality, and to pretransit and in-transit practices and environments. Plans include comparisons of break-bulk, palletized and containerized shipments, and decay-control treatments.

PROGRESS: Biphenyl residues in lemons are seldom over tolerance since lemons absorb one-third as much biphenyl as oranges when exposed to similar levels of biphenyl. Lemons injured by freezing or nitrogen storage absorbed excessive amounts of biphenyl indicating the involvement of a biological barrier. Biphenyl absorption by citrus occurred primarily in the rind tissue since separated orange peel absorbed four times more biphenyl than separated pulp segments.

SUPPORTED BY U.S. Dept. of Agriculture

4.0229, CHEMISTRY OF NEMATODES AND NEMATOCIDES

C.E. CASTRO, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-R0-SSE-2006)

OBJECTIVE: Trace chemical fate of nematocides in their path of migration from soils to extremities and edible portions of plants; quantitatively determine residues in each of these media.

APPROACH: In addition, it is intended to elucidate molecular processes occurring within nematodes and place host-parasite relationships of these animals on a chemical basis.

PROGRESS: Studies of the interactions of transition metal specie in organic and biological systems have revealed new insights into mechanisms of respiration, electron transport and biodehalogenation. These include: (1) The reaction of dimethylmethyl chromium carbenoids with olefins. (2) Peripheral attack in the reduction and oxidation of iron porphyrins. (3) Copper(I) substitutions. Scope and mechanism of cuprous acetylide substitutions. (4) Biodehalogenation. The pathway for transhalogenation and the stereochemistry of epoxide formation from halohydrins. (5) The oxidation of Iron(II) porphyrins by organic molecules. And describe respectively, (1) The reactions of a unique chromium carbenoid. (2) The importance of outer sphere electron transfer to hemes and hemoproteins and explanations for the reactivity of the globins and cytochromes. (3) The breadth and mechanism of Cu(I) acetylide substitutions. (4) The reversible enzymatic transhalogenation of epihalohydrins. (5) The kinds of organic molecules capable of oxidizing iron(II) porphyrins. Ubiquinone is suggested as a long range electron transfer agent.

SUPPORTED BY California State Government - Sacramento

4.0230, PHYSIOLOGICAL STUDIES ON WEEDS AND WEED CONTROL IN SOUTHERN CALIFORNIA

B.E. DAY, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-R0-PLS-1475)

OBJECTIVE: Biological and physiological studies will be undertaken to secure information on the life cycles and conditions for growth, reproduction and survival of weeds in southern california fruit orchards. Phytotoxicity of herbicides to orchard trees and weeds will be studied and these data applied to the field development of selective weed control programs.

APPROACH: Increased effort will be devoted to studies of nutgrass control in the Coachella Valley.

PROGRESS: Fruit production and quality were not affected in orchards treated with terbacil and bromacil for five years. Herbicide treatments for 10 years with diuron and simazine did not result in soil residue build-up in the surface 5 feet. Relative sensitivity of four citrus rootstocks to herbicides is, in decreasing order, Troyer citrus orange, Sweet orange, Cleo mandarin, rough lemon. Herbicide toxicity in decreasing order is bromacil, terbacil,simazine, diuron. Granular diclobenil control nutsedge 15 to 18 weeks but does not control bermuda grass; while terbacil and bromacil control bermuda grass, but not purple nutsedge on sandy soil. DNBP in weed oil sprays reduces oil required and expense of contact sprays. Contact herbicides reduce nutsedge population but do not eradicate nutsedge, even with repeated applications. Simazine, the most widely used herbicide, does not control summer annual grass in orchards. Diuron controls annual grass if application is properly timed. Contact herbicides are being used but costs are high. New herbicides promise to solve the problem. These include R7465, nitralin, trifluralin, VCS 634 and others. Tree tolerance and performance trials are established in several orchards.

SUPPORTED BY California State Government - Sacramento

4.0231, CHEMICAL CONTROL OF POST-HARVESTING FRUIT AND VEGETABLE DECAYS OCCURRING IN PACKING HOUSES

J.W. ECKERT, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-R0-SSE-1765)

OBJECTIVE: Develop a comprehensive research and evaluation program for chemical control of fruit and vegetable decay inciting microorganisms. Fungicide treatments will be developed to protect fruits and vegetables from decay and spoilage in packing houses, storage, transit, and during market period. Studies will be made of effect of applied chemical upon product quality.

APPROACH: With few exceptions most chemical materials can no longer be used readily as post-harvest treatments and comply with recent regulations of Food and Drug Administration. It is, therefore, essential that post-harvest fungicidal treatments for fruits and vegetables produced and shipped be examined in order to develop new and effective chemical treatments which comply with regulations and to provide information which will allow continued use of fungicides now successfully employed.

PROGRESS: A study of chemical structure vs antifungal activity in a series of lower primary aliphatic amines revealed that 3-methylpyrrolidine, sec-butylamine, pyrrolidine, 1-methylpropenylamine and cyclobutylamine were most active of 50 amines tested. (-) sec- butylamine was approximately 60 times more active than ( ) sec- butylamine. Sec-butylamine inhibited uptake of amino acids and protein synthesis by Penicillium digitatum. The postharvest fungicide o- phenylphenol is absorbed by both citrus fruits and pathogenic fungi. Excessive uptake by fruit causes high residues and injury. The quantity of o-phenylphenol absorbed by both oranges and spores of Penicillium digitatum was positively correlated with the concentration of undissociated o-phenylphenol in the treating solution. However, efficiency in decay control was correlated with factors favoring the selective absorption of the o-phenylphenate anion at potential infection sites on the surface of the fruit. Lower alkyl esters of o-phenylphenol were fungitoxic to both Penicillium digitatum and Diplodia natalensis but the methyl ether of o-phenylphenol was highly toxic only to the latter fungus. Substantially more free o-phenylphenol was isolated from the Diplodia culture indicating enzymatic cleavage of the ether.

SUPPORTED BY California State Government - Sacramento

4.0232, DEVELOPMENT OF SYSTEMIC FUNGICIDES FOR VERTICILLIUM WILT CONTROL

D.C. ERWIN, Univ. of California, School of Agriculture, *Riverside, California* 92502

The Research: Initiate a fundamental investigation to provide a basis for developing systemic fungicides capable of controlling verticillium wilt of cotton. Such research should: 1. Develop an understanding of the composition and characteristics of chemicals that are either directly toxic to verticillium wilt or which metabolically block its attack on, and the damage it does to the cotton plant; 2. Determine the structure specifications of such chemicals that will aid in their absorption, translocation and redistribution within the plant and 3. Investigate the possibility such chemicals may be most useful and effective if they are initially non-toxic to the plant and fungus, but by action of the plant or fungus, they produce reaction products that are fungicidal, or at least limiting, to growth of the pathogen.

SUPPORTED BY Cotton Incorporated - Raleigh, N.C.

4.0233, PEST CONTROL OF AVOCADO

W.H. EWART, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-R0-SSE-1340)

OBJECTIVE: Study the biology and chemical control of the approximately 25 species of insect, mite, and snail pests of avocado trees.

APPROACH: Develop rearing techniques for maintaining laboratory cultures of as many pests of avocado as feasible. Screen new insecticides for phytotoxicity and effectiveness against the various pests. Sreeen new insecticides against the various pests with special emphasis on greenhouse thrips and avocado brown mite. Study insecticidal treatment with respect to methods of application, dosages, formulation and compatability with various spray additives, phytotoxicity, effect on beneficial insects and other side effects, and residues on and in fruit.

PROGRESS: Avocado Brown Mite: Data obtained on effectiveness of narrow-range oil and light medium oil and light medium oil sprays for mite control was forwarded to State Department of Agriculture and manufacturers and formulators of horticultural spray oils for use in obtaining registration of these treatments. Greenhouse Thrips: In field trials sprays containing (1) malathion tetradifon or (2) carbofuran were outstanding in preventing fruit scarring; (3) pyrethrium oil was less effective but is a useful treatment since it does not upset the biological balance in the orchards and is relatively nontoxic to mammals; (4) formetanate was relatively ineffective. Omnivorous looper: A spray containing naled (Dibrom(Reg)) was not effective. Galecron(Reg), a possible treatment for this pest, was not phytotoxic to Haas, Fuerte or Bacon varieties when applied at 8 oz. actual compound per 100 gals.

SUPPORTED BY California State Government - Sacramento

4.0234, RESPROUTING OF CHAPARRAL

J.R. GOODIN, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-R0-PLS-2184-H)

OBJECTIVE: Attempt to develop an understanding of the phenomenon of resprouting in chaparral species and the autecological, anatomical, physiological, and genetic factors which influence this phenomenon.

APPROACH: The research will be conducted in the field, greenhouse, and laboratory, studying phenology, rate of resprouting, anatomy, growth and development in vitro, carbohydrate levels, and genetic variability of the dominant chaparral species.

PROGRESS: Tandex continues to look more promising than picloram in many situations for the control of Quercus dumosa. Phytotoxicity to grasses has been a serious detriment to the use of this chemical, and studies are in progress for use of the grid application technique to avoid damage to surface vegetation. Final

analyses of the experimental watersheds treated with combinations of 2,4-D, 2,4,5-T, and picloram show that essentially all residues have disappeared from the water and soil. A careful study of initial succession of vegetation following these treatments suggests that low residue levels may be phytotoxic to a few species, but in general, the pattern of succession approximates that which occurs following wildfires. Such information will be of use to land planners concerned with long-term ecological effects of herbicides. Studies of the polar transport of auxin are continuing in sterile culture. The new oxygen combustion method for C-determinations will be employed to study quantitative and qualitative changes in growth regulators. A selective bioassay was devised to evaluate extremely low concentrations of picloram in soil and water. This assay is selective for picloram, and is not confounded with effects from phenoxy-type herbicides.

SUPPORTED BY U.S. Dept. of Agriculture

4.0235, CONTROL OF INSECTS AND RELATED PESTS OF FLORICULTURAL CROPS, NURSERY STOCK AND TURFGRASSES

R.N. JEFFERSON, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-R0-SSE-1338-A)

OBJECTIVE: Develop more effective economical control measures for insect and related pests of greenhouse and field flower crops.

APPROACH: Laboratory and field studies of biology and habits of pests involved; laboratory and field studies with promising new materials and of equipment and methods of application.

PROGRESS: At 10 pounds of active ingredient per acre Dasanit, Akton, Landrin, Dyfonate, Furadan and Diazinon gave effective control of billbug larvae (Sphenophorus phoeniciensus) on Tifgreen bermuda grass. Lannate and Heptachlor were ineffective. Of 12 insecticides tested against the tobacco budworm (Heliothis virescens) on geraniums the most effective were Lannate, Azodrin, Monitor, C-9491 and C-2307. The materials were applied at 6 pounds of the active ingredient per acre in 300 gallons of water. In phytotoxicity tests on chrysanthemums and carnations the following materials (pounds active ingredient per 100 gallons of spray shown in parentheses) damaged both crops: Galecron (1/2 lb.), Fundal (1/2 lb.), Monitor (1 lb.) and Lannate (1 lb.). Compound 9491 (1 lb.) gave delayed injury to chrysanthemums.

SUPPORTED BY California State Government - Sacramento

4.0236, LIFE CYCLE, PHYSIOLOGY AND CONTROL OF PERENNIAL WEEDS AFFECTING SUBTROPICAL FRUIT CROPS

L.S. JORDAN, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-R0-PLS-1917)

OBJECTIVE: Study the life cycle and physiology of perennial weeds, and determine the best methods of controlling these weeds without adversely affecting subtropical fruit crops.

APPROACH: Initially the major effort will be devoted to studies of the physiology and control of nut grass and bermuda grass. Other important weeds will be studied under laboratory and field conditions when economic losses from the weeds are deemed sufficient to warrant such studies. In general, the investigations will be conducted as follows: Study the life cycle and physiology of the weed species and attempt to develop control methods based on physiological characteristics or growth habits of the plant. Investigate the effects of herbicides on the physiology of the weed species in an effort to improve the effectiveness of the herbicides.

PROGRESS: Evaluation of 140 herbicides in the field were made on 30 crops and 25 weed species. San 6706 and R 7465 are toxic to most annual crops but show promise in tree and vine crops. Kerb was selected for use in lettuce. Several potentially useful herbicides have been selected for further evaluation. Sorghum seed treatment with 1,8- naphtalic anhydride counteracts toxicity of EPTC, alachlor and diallate. The antidote did not counteract 10 other herbicides on several crops. Ten additional anhydrides and quinones were not antidotal to herbicides. Antidotes to herbicide will increase selectivity and weed control and reduce herbicide residues in the environment. Each antidote is specific to crops and herbicide groups. The antidotal action is not physical adsorption. Naphtalic anhydride is metabolically active and toxic to some plant species. It is translocated. Naphtalic anhydride is a powerful photosynthetic inhibitor being 1,000 times as effective as CMU on isolated, intact, spinach chloroplasts. 1,8-naphtalic anhydride may be the strongest inhibitor to photosynthesis yet discovered. Research with 1,8-naphtalic anhydride and potential antidotes will be emphasized. Ten plants have been developed which complete their life cycle in 30 days or less under controlled conditions. Their response to growth regulators and herbicides make them valuable for laboratory research with exogenous chemicals.

SUPPORTED BY California State Government - Sacramento

4.0237, DEVELOPMENT AND APPLICATION OF ANALYTICAL METHODS FOR THE DETERMINATION OF HERBICIDES AND PLANT GROWTH REGULATORS

L.S. JORDAN, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-R0-PLS-2007)

OBJECTIVE: Quantitative analytical methods will be developed for the determination of residues of herbicides and growth regulators in fruit, fruit products, the vegetative parts of fruit trees and in orchard soils. These methods will be employed in the practical determination of residue levels following field, and post harvest use of these chemicals in the production and processing of subtropical fruit.

APPROACH: Development of a procedure for the determination of 2,4- D in citrus fruits which has maximum sensitivity and a high confidence level. This will be used for the determination of residues in citrus where 2,4-D has been used as a herbicide. And also, study the amount of residue precent in lemons where 2,4-D has been used as a past harvest treatment.

PROGRESS: Fluorescence intensity as measured in a spectrophotofluorometer was used as the basis for the development of a method for the determination of 1-naphthalineacetic acid in citrus tissues. The cleanup for this sensitive detection method is accomplished by selective extraction, liquid-liquid partitioning and permanganate dilution. Inclusion of a silica gell cleanup column was necessary for peel samples. The method has a sensitivity of 0.1 ppm based on a 25 g sample. Preliminary analysis of field treated samples before the method was completed indicated that no naphthaleneacetic acid residues were present in the peel or pulp. It was determined that an ascorbate CuSO(4) system would degrade several herbicides to various degrees. An acid pH favored the reaction. Eptam, vernolate, and alachlor gave the most response and to a lesser degree, diallate, CDAA, and CDEC. Some of the breakdown products found were ethylene, ethane, propylene, and butene. Thirty different soils and eptam were tested in determining if such a degradation might occur in nature, but similar degradation did not occur.

SUPPORTED BY California State Government - Sacramento

4.0238, DETECTION AND DETERMINATION OF FUNGICIDES, BACTERICIDES, AND CHEMOTHERAPEUTIC AGENTS

M.J. KOLBEZEN, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-R0-SSE-1998)

OBJECTIVE: Development of analytical methods, if none exist, and application of these methods to residue analysis of every crop-fungicide combination important to southern California agriculture. Certain bactericides and possibly chemotherapeutic agents will be considered.

APPROACH: With some pesticides it is import also to study breakdown pathway since metabolites and decomposition products could be toxic. Whenever possible, field persistence and rate of decay of deposits of pesticides will be studied.

PROGRESS: Thiabendazole (TBZ) and benomyl are two promising decay control agents for citrus. TBZ is in commercial use, benomyl is in the experimental phase. A simple analytical procedure has been developed for analyzing wax formulations for TBZ, also a residue method for determining the magnitude of TBZ deposited on citrus fruit when applied by some commercially practical method. Similar types of analyses for benomyl are under study. Since many plants are sensitive to bromide ion in soils, some soils are being analyzed for bromide content resulting from

hydrolysis of methyl bromide (MeBr) when these soils are fumigated with MeBr. A correlation between bromide content and such factors as dosage, moisture, and pH is being sought. To date, correlations are vague. The analysis of soil atmospheres for MeBr concentrations is continuing in a long range project to determine the relation of soil characteristics to optimum diffusion to deeper regions for Armillaria mellea control.

SUPPORTED BY California State Government - Sacramento

4.0239, CONTROL OF NEMATODES IN NURSERIES AND ON PLANT MATERIALS

A.R. MAGGENTI, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-R0-SSE-2044)

OBJECTIVE: Identify species of nematodes and their distribution around plants in nursery culture. Evaluation of nursery plants as nematode host and carriers, and for resistance or susceptibility of nematode disease. Devise and evaluate methods for obtaining eradication, or near-eradication, of nematodes from nursery soils and nursery plants.

APPROACH: Soil and root samples will be collected from plants associated in and with nursery culture, and suspected plant parasitic nematodes identified. Greenhouse studies will be made with these nematodes to study pathogenicity and host range. After consideration of properties of available nematocides, a series of materials and dosages will be selected that are most likely to achieve eradication or a high degree of control of nematodes in nursery soils and plants. Treatments will be compared in replicated field trials, giving special consideration to sampling methods and detection probability. In laboratory and greenhouse evaluate hot water treatments and chemicals available from industry as eradicants of nematodes in or on nursery grown materials.

PROGRESS: Dipping trials with the following chemicals were conducted for the elimination of rootknot nematodes (Meloidogyne spp.) from plant roots: trimethoxy-2-bromopropane; dimethoxy-2-bromobutane; alpha-ethyl, beta-dibromopropionate; alpha-bromo, beta-ethyl propionate 1, 1-dibromo-2, 2-dietoxy-ethane; bromodine; V-C 13; 21149 (Union Carbide Co.); Bayer 68138; V-C 9-104; Stauffer N 3056; Shell SD 4965; Zinophos; Chemagro 5461; Niagra 15267; E. Lilly 300; Dupont 1410; and Lannate. None of these chemicals completely eliminated nematodes from the roots without injuring the plant. The most promising of these chemicals were V-C 13; Zinophos; Bayer 68138; and Dupont 1410.

4.0240, THE BIOCHEMISTRY AND MODE OF ACTION OF HERBICIDES

J.D. MANN, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-R0-PLS-2005-H)

OBJECTIVE: The objective of this project is to secure information on the mode of action of selective herbicides used or potentially useful in crop production. The machanism of resistance of some plant species to herbicides will also be studied.

APPROACH: Radioactive precursors of plant metabolites will be administered to plant tissues, in the presence of a wide variety of herbicides. Possible effects of these herbicides upon metabolism will be studied by tracer procedures.

PROGRESS: The nitrogen content of carrots and ryegrass was increased by pre and postemergence treatments with nitralin, trifluralin, and 4 symmetrical triazine herbicides. Several metabolites of terbacil and bromacil were isolated from Troyer and Koethen sweet orange seedlings by fluorescence TLC. Identification of the metabolites is in process. Simazine is converted to hydroxy simazine and dealkylated products in citrus seedlings. Dealkylation but not hydroxylation occurs in nutrient solutions surrounding citrus roots; simazine translocates readily in the apoplast and conversion occurs in roots, stems and leaves of citrus. An unidentified metabolite occurs in citrus fruit. Positive identification of simazine metabolites in citrus is underway. TLC systems were developed for separation of simazine and three metabolites. Simazine is more toxic to citrus trees growing in soil than trees growing in nutrient solution, whereas monuron is more toxic in nutrient solution. Several metabolites of monuron and photolytic degradation products have been isolated with TLC and are being identified.

4.0241, REACTIONS OF VEGETABLE CROPS TO APPLIED CHEMICALS, EXCLUSIVE OF NUTRIENTS

L. RAPPAPORT, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-R-VCR-1175-D-R)

OBJECTIVE: Increased fruit setting; improved seed yield in breeding projects; control of flowering; control of vegetative growth; control of dormancy; effects of insecticidal, fungicidal, and phytocidal chemicals on yield, appearance, texture, taste, aroma, harvesting and storage practices, etc. of vegetable crops.

APPROACH: NOT-PROVIDED

PROGRESS: Cooperative screening trials were conducted involving 76 herbicide chemicals at 3 rates each on 8 vegetable crops in a spring trial and 80 chemicals at 3 rates each on 9 vegetable crops during the fall planting season. Studies on the effect of Dacthal on onion emergence were continued with emphasis on the effect of rate of herbicide and depth of planting over a period of time beyond the flag stage of the onion seedling. Ten chemicals were tested as preemergence herbicides or as post emergence treatments on asparagus seedlings from 2 to 10 weeks after emergence. Effective herbicides are necessary to make possible direct seeding for establishment of asparagus plantings. The chemical 2-chloroethanephosphonic acid (Ethrel) was tested on tomatoes to accelerate maturity. Ethrel at 250 and 1000 ppm increased both number and weight of early fruit harvested, although total yield was not greatly affected. Fruit maturity was advanced from 7 to 10 days by Ethrel treatment. Studies have also been initiated on the effect of this chemical on alteration of sex expression in pickling cucumbers and cantaloupe.

4.0242, CHEMICAL STRUCTURE RELATED TO SYSTEMIC ACTIVITY, METABOLISM, MODE OF ACTION, AND FATE OF CHEMICALS IN COTTON PLANT

H.T. REYNOLDS, Univ. of California, School of Agriculture, *Riverside, California* 92502

The Research: A detailed study of the metabolic behavior of systemic in cotton plants plus appropriate structural modifications is the key to the development of effective systemic insecticides. Research should include: 1. A detailed study of chemical structure related to systemic activity in the cotton plant. 2. Basic studies on the metabolism of systemics in the cotton plant as related to systemic activity aand toxicity to cotton insects. 3. Laboratory and field plot studied to evaluate promising candidate compounds for cotton insect control.

SUPPORTED BY Cotton Incorporated - Raleigh, N.C.

4.0243, COTTON PATHOLOGY FOR THE IRRIGATED WEST

R.H. GARBER, U.S. Dept. of Agriculture, Crops Research Division, *Shafter, California* 93263 (0200-02-08)

OBJECTIVE: Reduce the production hazard of verticillium wilt; improve seedling survival and vigor by more efficacious seed and soil treatment; influence of boll constituents on incidence and severity of rots.

APPROACH: Varietal reactions to different cultural practices, irrigation frequencies and duration, nutrient levels, plant populations, crop sequences, and duration, nutrient levels, plant populations, crop sequences, and precision tillage; cooperate in regional seed and soil fungicide studies. Tag several thousand flowers to identify bolls, harvest boll samples periodically for laboratory study of organisms on the surface, and of boll constituents; use boll washings for bioactivity trials, also carpel and locule constituents. Survey main production areas periodically for presence of bacterial blight.

PROGRESS: Field tests indicated significant increases in plant survival resulting from effective seed treatment with protectant and protectant-systemic fungicide seed treatments. Studies on multichemical application at planting time were continued.

Stands were improved by the use of fungicides. In the absence of a fungicide, phorate, either as granules or seed treatment, reduced stand. Phorate used as a seed treatment also reduced plant vigor. Several herbicides also reduced plant vigor. Data indicate that environment exerts a major influence on chemical interactions and any factors that delay emergence contribute to increased damage or to the deleterious effect of chemical treatment. Studies on crop rotations indicate the value of a barley crop between cotton crops in reducing loss due to verticillium wilt. When cotton crop residues were removed from fields, the level of verticillium wilt was significantly reduced. Results of five years of work indicate that temperatures can mask inoculum differences and become the determining factor in disease severity. Studies on virulence of Verticillium albo- atrum indicated repeated passage through cotton resulted in increased virulence. Cotton treated with the systemic fungicide benomyl exhibited less wilt symptoms, was taller, and yielded more cotton. Bioassay of leaves in September indicated presence of benomyl after two post- planting soil applications.

SUPPORTED BY U.S. Dept. of Agriculture

4.0244, BIOLOGY AND CONTROL OF WEEDS IN WESTERN IRRIGATED COTTON

J.H. MILLER, U.S. Dept. of Agriculture, Crops Research Division, *Shafter, California* 93263 (0710-01-06)

OBJECTIVE: Develop safe, practical, economical and effective weed control methods in irrigated cotton.

APPROACH: Conduct physiological, morphological, anatomical, ecological and agronomical research on factors affecting absorption, penetration and translocation of herbicides in plants; research on the performance, persistence, and movement of herbicides in soil as affected by water management, time and method of application, and soil characteristics; and research on combining chemical and nonchemical methods of control.

PROGRESS: Data from 2 years of field experimentation do not indicate that the insecticides phorate or disulfoton alleviate inhibition of lateral roots of cotton by the herbicides trifluralin or nitralin applied before planting. An alleviating action has been reported from research in Arizona. Continuing research indicates that spraying nitralin or trifluralin beneath the soil surface in horizontal bands or injecting them in the soil in parallel lines may be more efficient than incorporation in the soil with powered equipment with respect to weed control where applications are made as cotton is planted in moist soil. Sweep cultivators appeared equal to rolling cultivators for incorporation of herbicides applied at layby of cotton.

SUPPORTED BY U.S. Dept. of Agriculture

4.0245, SUGAR BEET DISEASES

J. ALTMAN, Colorado State University, Agricultural Experiment Sta., *Fort Collins, Colorado* 80521 (COL00082)

OBJECTIVE: Study etiology of sugar beet Rhizoctonia and nematodes and determine effective control measures. Study modifications of disease and growth in beets due to herbicides and pesticides.

APPROACH: In vitro evaluation of sugar beet herbicides on Rhizoctonia and Heterodera schactii. Histological studies of the inoculated and uninoculated plants grown in Tillam-treated greenhouse soils.

PROGRESS: Predisposition tests were set up in the field and in temperature tanks to evaluate the effect of combinations of Rhizoctonia, Heterodera schachtii, and two herbicides on disease interaction. Field experiments confirmed previous observations in Colorado that Pyramin and Roneet can predispose plants to increased Rhizoctonia damage, in the absence of nematodes. Increased nematode reproduction was also observed in the absence of Rhizoctonia. Combinations of nematodes and Rhizoctonia resulted in more severe disease when beets were grown in herbicide treated soil than that resulting from such combinations grown without herbicides. (This research supported jointly by Projects 0215 and 0082).

SUPPORTED BY U.S. Dept. of Agriculture

4.0246, CONTROL OF WEEDS AND INSECTS IN SUGAR BEETS

A. DOTZENKO, Colorado State University, School of Agriculture, *Fort Collins, Colorado* 80521

The crop sequence in which sugarbeets followed beans had lower weed populations prior to thinning than did sugarbeets following either barley or corn. Lowest weed populations resulted in highest root yields. The rate and time of application of nitrogen fertilizer did not influence root yields and weed populations. The low-plus-residual nitrogen and high nitrogen treatments did reduce sucrose percent and purity which lowered sucrose production and tons of recoverable sugar per acre. The application of high nitrogen also reduced beet numbers prior to thinning and harvest. The application of preplant and post- emergence herbicides significantly lowered populations of all weed species. Kochia was controlled to a degree by the use of herbicides. However, significant populations of this barley left no residual damaging effects on the following beet crop. Herbicides did reduce beet stands prior to thinning, but because of weed competition in the no herbicide treatment the use of herbicides resulted in more beet numbers at harvest. The yield of all weed species prior to thinning and at harvest was lowered due to the use of herbicides. Herbicides significantly increased root yields, sucrose production and tons of recoverable sugar even though they caused reductions in sucrose and recoverable sugar percentages. Interaction of treatments revealed that most weed populations can best be controlled by a proper combination of crop sequence, nitrogen level and herbicides.

Varying kochia densities reduced light intensities as compared to the light received beneath a weed-free beet canopy. Significant reductions in the yield of roots and tops were recorded for each increase in density.

SUPPORTED BY Great Western Sugar Company

4.0247, FACTORS AFFECTING THE TOXICITY AND SELECTIVITY OF PRE-EMERGENCE SOIL HERBICIDES

J.L. FULTS, Colorado State University, Agricultural Experiment Sta., *Fort Collins, Colorado* 80521 (COL00083)

OBJECTIVE: Investigate the role of soil factors as they relate to pre-emergence soil herbicides. Correlate the physical and chemical characteristics of pre-emergence herbicides with the phytotoxic action, selective action (as between crops and weeds), their movement and persistence in the soil. Interpret the interactions of the soil factors and herbicide characteristics as they affect specific weeds and crop plants.

APPROACH: Laboratory determination of major soil characteristics of a few typical Colorado soil types on which pre-emergence herbicides are being used. Greenhouse, laboratory and field tests with a limited number of herbicides to determine relative toxicities, selective action, movement and persistence. Correlation of A and B.

PROGRESS: Herbicides studied were picloram and dicamba used as soil incorporated materials. Plant pathogens studied were several soil inhabiting forms of Fusarium and Rhizoctonia solani. Host plants included both pathogen susceptible and resistant varieties of pinto beans, sugar beets, and tomatoes. Activities of the fungi were measured and studied. Data were statistically analyzed. Thirteen main experiments were conducted. Dicamba at 5 ppm strongly restricted the growth of both Rhizoctonia solani and Verticillium albo-atrum both important soil borne plant pathogens. Picloram greatly stimulated chlamydospore formation by Fusarium sp. Spores of Fusarium oxysporum f. lycopersci and F. solani f. phaseoli showed normal germination when low concentrations of picloram or picolinic acid or dicamba were present. Neither the absence of carbon or nitrogen sources nor the presence of both in different media influenced the germinability of Fusarium spores. Although picloram was applied at a concentration ten times lower than dicamba to a soil with a high potential for causing bean root rot due Fusarium solani f. phaseoli, it (the picloram) increased the number of propagules to a much higher

level than dicamba. Aspergillus niger and Penicillium sp. grow on the surfaces of picloram and picolinic acid solutions without any other source of nutrient.

SUPPORTED BY U.S. Dept. of Agriculture

4.0248, RESPONSE OF PLANTS AND PLANT COMMUNITIES TO SUSTAINED USE OF HERBICIDES

J.L. FULTS, Colorado State University, Agricultural Experiment Sta., *Fort Collins, Colorado* 80521 (COL00261)

OBJECTIVE: Determine effects of repetitive application or pollutional levels of herbicides on plant communities.

APPROACH: Determine effects of repeated applications of pre- emergence and post emergence herbicides on bluegrass quality and production. Study environmental factors affecting toxicity and selectivity of preemergence soil herbicides. Determine the influence of soil temperature moisture, microflora and organic matter on the disappearance of pyrazon, dicamba and picloram. Determine the direct and interacting effects of picloram and dicamba on the two soil plant pathogens -- Fusarium sp. and Rhizoctonia sp.

PROGRESS: Field plots of 5 varieties of Kentucky bluegrass and various subplots have been established. The long time effects of annual applications of 2,4-D, dacamine, betasan, dacthol, banvel-D, bandane and silvex on broad-leaf and annual grass weed populations, with and without nitrogen fertilization, will be studied. Measurements at timely intervals of turfgrass dry weight production, turf color, and density will be used as measures of response. Studies will also include residue samples and root studies to help explain long time effects.

SUPPORTED BY U.S. Dept. of Agriculture

4.0249, WEED CONTROL IN SUGARBEETS FOR THE INTER-MOUNTAIN WEST

E.E. SCHWEIZER, Colorado State University, U.S.D.A. Crops Research Div., *Fort Collins, Colorado* 80521 (0710-01-07)

OBJECTIVE: Develop principles, methods, and practices to control weeds in sugarbeets in the inter-mountain West.

APPROACH: Use laboratory, growth chambers, greenhouse, and field facilities to conduct experiments on the evaluation of new herbicides for weed control in sugarbeets when applied as preemergence, preplanting and postemergence treatments; on the penetration, absorption, and translocation of herbicides in sugarbeets and weeds; on the penetration, movement, persistence of sugarbeet varieties, genetic strains of sugarbeets, and associated weeds to herbicides under varying environmental conditions.

PROGRESS: For the first time, we produced normal yields of sugarbeets without the use of hand-labor for weed control by supplementing cultivation with effective herbicides. We applied a mixture of 3 lb/A of cycloate plus 1 lb/A of 3'-(N- isopropylcarbamoyloxy)propionanilide before planting, and then applied 2 lb/A of phenmedipham as a postemergence treatment. This weed control system minimized competition from weeds all season, and the yield of roots and sucrose per acre equalled that of hand-weeded plots. -- Nitralin and trifluralin, applied at 0.75 lb/A as a post-thinning treatment, effectively controlled Amaranthus retroflexus. Trifluralin produced more aberrant roots than did nitralin, but the number of aberrant roots was reduced significantly when soil surrounded the hypocotyledonary tissues at the time of application. Both herbicides induced twisting of sugarbeet roots at 0.05 lb/A in a simulated residue study. -- Dicamba, applied at 2 lb/A in August 1967, reduced the competitiveness of Convolvulus arvensis for 2 years, and residues in the soil dissipated to a level that did not significantly affect either the production of sorghum planted 13 months later, or of sugarbeets planted 25 months later.

SUPPORTED BY U.S. Dept. of Agriculture

4.0250, PRODUCTION AND QUALITY OF APPLES IN HIGH DENSITY PLANTINGS USING DWARFING ROOTSTOCKS

J.K. STACEY, Colorado State University, Agricultural Experiment Sta., *Fort Collins, Colorado* 80521 (COL00157)

OBJECTIVE: Effect of different training procedures on 4 varieties of apples using 7 dwarfing rootstocks. Effect of herbicides on production and quality of same. Effect of Floraltone on lateral attachment and return bloom. Effect of Alar on color and size and the effectiveness as a stop-drop. Effect of GA 47 on fruit shape. Effect of different high density planting systems on productio and quality. Differential uptake of nutrient elements on variety/rootstock combinations. Effect of scoring and limb bending on production and return bloom. Effect of mechanical pruning procedures on tree development and production.

APPROACH: Soil treatments to be uniform. Blocks of trees to be randomized and replicated. Measurements to be taken to indicate vigor, precocity, order of blossoming in season, biennial bearing, uptake of elements, fruit color, size, yields, phytoxicity of chemicals and costs of establishing and maintaining all systems of training and spacing.

PROGRESS: 4 training systems x rootstocks x 2 varieties (3 replications) Second year training procedures completed. Measurements made of terminal growth, diameter of trunks, angle of limb attachment. Leaf analyses completed. All data ready for processing. 5 treatments x 2 rootstocks 1 interstem x 2 varieties (4 replications) Training procedures completed. Growth hormones applied Measurements were same as above. Data ready for processing. 1 training system x 5 rootstocks x 4 varieties (3 replications) All procedures and measurements, as above, completed. Data ready for processing. 2 treatments x 7 rootstocks x 2 varieties (3 replications) Above measurements made. Data ready for processing. Management Procedures - Job analysis records kept on all treatments. Herbicides applied and observations made for phytotoxicity. All trees treated with CuSO(4) and special irrigation method initiated to observe the effect on Phytophthora cactorum.

SUPPORTED BY Colorado State Government

4.0251, HERBICIDE SCREENING STUDIES ON SUGAR BEETS

E.F. SULLIVAN, Great Western Sugar Company, *Longmont, Colorado* 80501

The objectives of the research are (a) to evaluate weed control and crop selectivity response of candidate herbicides on sugar beets and (b, to define reliable and effective chemical weeding schemes employing the split-placement technique.

1. Potential of preplant-incorporated, preemerge, postemerge and layby placements and herbicides are evaluated. 2. Herbicide studies conducted under constant and logarithmic dosages in the field and greenhouse. 3. Assay of relative presence or absence of chemical residue in plant material and soil integral part of program.

4. Computer analysis of data including probit analysis.

SUPPORTED BY Great Western Sugar Company

4.0252, DYNAMICS OF FUNGICIDAL ACTION

J.G. HORSFALL, Conn. Agric. Expt. Station, *New Haven, Connecticut* 06504 (CONH00634)

OBJECTIVE: Discover the chemical and physical bases for fungicidal action, and use these discoveries for building newer and better fungicides.

APPROACH: Attempts are made to correlate fungicidal activity of new and old fungicides with their chemical structure. The clues thus disclosed lead to possible mechanisms of action, methods by which the fungicides disrupt the normal physiology of fungi. A study of the molecular structure or physical and chemical properties of the active compounds allows theories to be constructed concerning fungicidal mechanisms. These theories are then tested experimentally. The theories of fungicidal action are tested partly in terms of fungitoxicity data and principally by physiological and chemical techniques. In the testing of practicality of application of such principles field applications are made using apple scab, celery leaf blights, and Helminthosporial, Curvularial, and Rhizoctonial blight of turf grasses.

PROGRESS: 2 percent of chemicals tested on sporulation of Alternaria solani produce deformity of the conidium. The long narrow spore is broken and cells at the bend become globose and have little contact with each other. The active compounds include

thiones, thiols, and some non-sulfur chelators. The compounds may act by preventing synthesis of mucilage or breaking bonds that hold the cells of the conidium together. Four antisporulants including two thiol reagents effective in laboratory and greenhouse studies showed little effect on reducing early blight disease in the field. All of the compounds were toxic to tomato foliage in the field test. Injury to peach foliage by the combination spray of dodine and captan used for control of bacterial spot increases with the concentration of active ingredients and with temperature. The increased injury of the combination over either alone appears to be due to dodine, a surfactant, which increases the amount of captan entering leaves. Decomposition products of captan are phytotoxic when formed in the interior of the leaf. Present formulations of dodine and captan can injure peach foliage if concentrates are applied when the air temperature exceeds 27 C.

SUPPORTED BY U.S. Dept. of Agriculture

4.0253, CHEMICAL CONTROL OF WEEDS IN POTATOES

A. HAWKINS, Univ. of Connecticut, Agricultural Experiment Sta., *Storrs, Connecticut* 06268 (CONS00354)

OBJECTIVE: Determine effects of chemicals for control of weeds, especially grasses which germinate before potatoes emerge or are a problem early in growth of potatoes. Determine effect of chemicals, and method of application for control of weeds which germinate late in the season. Determine effect of chemicals in suppressing and/or eradicating nutgrass in pototoes.

APPROACH: Objective 1, 2, 3. Compare three or more rates of chemicals in replicated plots in growers fields for control of either early germinating grassy weeds, weeds which germinate late in the season, or nutgrass. Observations will be made on weed control, and effect on potato plants. Yields and residues will be determined.

PROGRESS: In a comparison of rates of diphenamid, alone and with DNBP, and rates of EPTC 5G, applied late preemergence to Katahdin potatoes, excellent control of crabgrass was obtained with 3 lbs. diphenamid plus 2 1/4 lbs. DNBP per acre, and with EPTC at 4 lbs. active per acre. These treatments gave control of crabgrass superior to 3 lbs. of diphenamid alone per acre. DCPA at 7 1/2 lbs. active per acre gave acceptable control of crabgrass. DCPA and EPTC were applied for potatoes at the 4-inch stage following ridge-off and second weeding in a field infested with barnyard grass. DCPA gave poor control of barnyard grass at rates up to 9 lbs. active per acre, the highest rate used. EPTC gave good control of barnyard grass at 4 lbs. active per acre. Potatoes treated with EPTC at 8 and 12 lbs. per acre were slightly less vigorous early in the season as compared with those which received 4 lbs. EPTC per acre. Slightly lower yields were obtained to higher rates of EPTC, but the yield differences were not statistically significant. Where nutgrass is not a problem, a single application of diphenamid with DNBP for season-long weed control has several advantages over the present practice of applying EPTC. Incorporation and dry soil are required for proper EPTC application. Stunting and decreased yields have occurred with EPTC primarily with early applications at higher rates.

SUPPORTED BY Connecticut State Government

4.0254, BIOLOGY AND CONTROL OF INSECTS ON TOBACCO

J.B. KRING, Univ. of Connecticut, Agricultural Experiment Sta., *Storrs, Connecticut* 06268 (CONH00376)

Progress:: Cyclodiene-resistant root maggots, Hylemya spp., are controlled by a preplant soil application of diazinon. This treatment has been used for several years and detectable field resistance has not yet been observed. Several other insecticides were tested this year as possible substitutes for diazinon, should resistance develop. There were applied to the row and then raked lightly into the soil. They were applied as granular formulations in dosage series to randomized replicated plots. The most effective compounds were diazinon, Dasanit (registered trademark), Dursban (registered trademark) and carbofuran. Next in effectiveness was Bux10 (registered trademark). There was an indication that disulfoton might be effective at rates in excess of 4 pounds of actual insecticide per acre. Carbofuran was phytotoxic to tobacco during the initial stages of growth. By bloom the plants had outgrown the early injury. Heavy mortality of earthworms occurred following treatment with 4 pounds of Bux10 and with 1, 2 and 4 pounds of carbofuran. It was reported last year that flies produced by these maggots are attracted to both white and yellow painted stakes. This year white stakes were used to attract flies to poisoned organic fertilizer. Dyfonate (registered trademark), GA493 and Lannate (registered trademark) combined with organic fetilizer killed flies attracted by the stakes to this mixture. Gardona (registered trademark) and VCS506 were not effective when used in this manner.

SUPPORTED BY Connecticut State Government

4.0255, ACTION OF SELECTIVE CHEMICALS ON MICRO-ORGANISMS AND HIGHER PLANTS

R.W. MILLER, Univ. of Delaware, Agricultural Experiment Sta., *Newark, Delaware* 19711 (DEL00074)

OBJECTIVE: Investigate the effects of chemicals on selected organisms.

APPROACH: The fungi Uromyces phaseoli typica. and Colletotrichum lindemuthianum, the bacterium Xanthomonas phaseoli, the nematode Meloidogyne incognita and the snapbean plant Phaseolus vulgaris will be used as tests models. Electrophoresis will be used to separate certain enzymes from each model for comparative studies before and after absorption of selectively active fungicides. Lipids, phosphorylated compounds, amino and organic acids, and carbohydrates will also be examined.

PROGRESS: A screening procedure has been devised to rapidly test effects of various agricultural chemicals on penetration and pathogenicity of various plant parasitic nematodes. This technique will facilitate evaluation of observed problems of crop reduction associated with the application of herbicides to sandy soils in Delaware. A literature review has revealed numerous similar observations throughout the United States. Two publications were submitted (see below) on the results of a field test. Work with Vitavax and Plantvax has been discontinued.

SUPPORTED BY U.S. Dept. of Agriculture

4.0256, CONTROL OF WEEDS IN AGRONOMIC AND VEGETABLE CROPS WITH HERBICIDES

E.M. RAHN, Univ. of Delaware, Agricultural Experiment Sta., *Newark, Delaware* 19711 (DEL00011-H)

OBJECTIVE: Evaluate herbicide combinations for control of nutgrass in corn, tomatoes, peppers, and lima beans. Evaluate herbicide combinations on soybeans, and cucurbits to widen spectrum of weed control, to increase margin of crop safety, and to reduce herbicide residues. Evaluate long term effects of terbacil on asparagus. Study mode-of-action and basis-of-selectivity of alachlor and possibly other new herbicides. Monitor excessive persistence of herbicide residues, contamination of surface and ground water by herbicides, and reduction of nodulation leguminous crops by herbicides.

APPROACH: Combinations of herbicides at varying rates will be used on several crops on soil heavily infested with nutgrass. Combinations of herbicides at varying rates will be used on several crops on soil infested with, or seeded to, such persistent weeds as jimsonweed, velvet-leaf, ragweed, and morninggiory. In mode-of-action studies, entrance of alachlor into root and shoot, as well as translocation and accumulation will be studied using gas chromatography and tritium labeled alachlor. Effect on respiration, protein synthesis using tritium labeled leucine, RNA synthesis using tritium labeled uradine will also be studied.

PROGRESS: Control of northern nutgrass in several vegetable crops was evaluated using two new herbicides, alachlor and butylate. On potatoes, alachlor, 4 lb/A, was as effective as the standard EPTC, 6 lb/A. On tomatoes and peppers, alachlor, 4 lb/A was effective on nutgrass but did injure the plants somewhat, but without yield reduction. Butylate caused crop injury. On sweet corn, alachlor, 2 lb/A, and butylate, 3 lb/A, both controlled nutgrass but butylate caused some yield reduction. On lima beans, alachlor, 2 lb/A, caused some early crop injury but did not reduce yields. In mode-of-action studies, alachlor, 1 ppm, did not inhibit

uptake of H-leucine by oat coleoptiles, but did cause 65% inhibition of incorporation of H-leucine into protein and 50% reduction of respiration. Terbacil, 3/4 lb/A, provided full season weed control on established asparagus without affecting yield.

SUPPORTED BY U.S. Dept. of Agriculture

4.0257, CHEMICAL CHANGES IN PESTICIDE RESIDUES DURING PROCESSING OF FRUITS AND VEGETABLES
R.P. FARROW, Natl. Canners Association, *Washington, District of Columbia* 20036 (W3-4-102(C))

OBJECTIVE: Identify degradation products of chlorinated hydrocarbon, organophosphate and carbamate pesticide compounds in fruits and vegetables after processing.

APPROACH: Subject fruit and vegetable buffered suspensions, juices, and processed products, containing pesticides, to the heat encountered during conventional canning. Evaluate product-pesticide combinations encountered commercially. Use radiotracer techniques as needed.

PROGRESS: Spinach and apricots with added pesticides were canned, given appropriate heat processes, and stored 1 year at ambient temperature and at 100 F. The carbamates, carbaryl, maneb, zineb, and ziram, were 87-100% destroyed during processing of spinach but only 12- 40% in apricots. The organophosphorus compounds, diazinon, guthion, and methyl parathion, had disappeared completely from spinach and apricots after a year at either temperature. Sixteen percent of the malathion remained in apricots after 1 year at ambient temperature. Trithion showed 29% survival in spinach and 16% in apricots under the same conditions. As a group, the organochlorine pesticides were most stable, particularly thiodan and TDE. Captan and methoxychlor had entirely disappeared from both products after 1 year at 100 F. Lindane and toxaphene were of intermediate stability. TDE is the principal transformation product of DDT in thermally processed spinach. Very little DDE was found. A third, unidentified transformation product, present in substantial amount, is chromatographically much more polar than DDT, TDE, or DDE.

SUPPORTED BY U.S. Dept. of Agriculture

4.0258, BIOLOGY AND CONTROL OF INSECT AND OTHER PESTS OF CUT FLOWERS
E.G. KELSHEIMER, Gulf Coast Agric. Expt. Sta., *Bradenton, Florida* 33505 (FLA-GC-01269)

OBJECTIVE: Study biology of pests that attack cut flowers and develop methods for their control. Control of wireworms attacking gladiolus corms. Control of mites, leafminers and other pests on field grown and potted chrysanthemums. Control of thrips and mites in carnation and roses.

APPROACH: New materials will be tested for insecticidal properties as well as phytotoxicity to plants and compatibilities among insecticides, fungicides, nutrients and miticides.

PROGRESS: Fall tests of materials for insect and mite control on Yellow Ice-berg field-grown chrysanthemums showed that better control of leafminers was achieved with combinations of Lannate LA (250/A) and Azodrin (3.2 EC). Lannate W.P. and Azodrin used at the same rate resulted in marginal chlorosis on the leaves. Mites, loopers and army worms were not serious problems.

SUPPORTED BY Florida State Government - Tallahassee

4.0259, NEMATODES - THEIR EFFECTS AND CONTROL ON VEGETABLE AND ORNAMENTAL CROPS
A.J. OVERMAN, Gulf Coast Agric. Expt. Sta., *Bradenton, Florida* 33505 (FLA-GC-00992)

OBJECTIVE: Effect of specific plant parasitic nematodes, alone or associated with soil microorganisms, on vegetable and ornamental crops. Effect of cultural practices and crop rotations on nematode population levels. Chemical methods of controlling economically important nematodes.

APPROACH: Host-parasite relationships of nematodes found associated with economic crops are being studied under controlled environments in growth rooms. Nematode species and population fluctuations in a summer cover crop x potato rotation are being evaluated on 2 soil types in the field. Effects of sub-soiling are being evaluated. Soil fumigants and non-volatile chemicals are being applied in infested fields and as plant dips for nematode control.

PROGRESS: Gladiolus: Root-knot nematodes in corms were controlled by 15 minute pre-plant corm dips containing Ziniphos 1 pt/100, but the treatment was phytotoxic. Ceresan L, 4 pt/100, not nematicidal, gave best flower production. Addition of Zinophos to Ceresan L dip controlled root knot, but cut flower production 50%. MBR 5667 .75 lbs/100 was nematicidal and improved yields. MoCap 1 pt/100 did not eliminate galling, but improved yields. Spinach: Dasanit 10 paa dwarfed seeded spinach. Vapam Dasanit, MoCap, Furadan, or Temik 100 paa increased emergence 100% over Vapam alone. Onions: Furadan or Temik 10paa bleached the foliage tips. Yields were increased over 100% by Dasanit, MoCap, Zinophos Thimet. Control of Trichodorus christiei with these materials lasted 27 weeks. Leatherleaf fern: MoCap 20 paa and Dasanit 10 paa controlled Pratylenchus penetrans in 3 established plantings for 9 months. P. penetrans recovered 6 months after application of Furadan or Temik 10 paa; Tirpate 10 paa applied as a drench gave 3 months control of the nema. Pre-plant rhizome-root dips (15 min.) with Bayer 68138 1/4 pt/100 or MoCap 1/4 pt/100 controlled P. penetrans harbored within the tissue; neither was phytotoxic. Ceresan L 4 pts/100 used as a fungicide killed the fern. On incubation, no nematodes were recovered from Pratylenchus-infected roots which had been dipped 15 minutes in Tirpate 1.3 pts/100 and Bayer 68138 1,000 ppm.

SUPPORTED BY Florida State Government - Tallahassee

4.0260, BIONOMICS OF THE PLANT NEMATODE TRICHODORUS CHRISTIEI
A.J. OVERMAN, Gulf Coast Agric. Expt. Sta., *Bradenton, Florida* 33505 (FLA-GC-01193)

OBJECTIVE: Not Provided

APPROACH: Not Provided

PROGRESS: Granular incorporation at planting of Ambush (10 lb/A), MoCap (30/A), Dasanit (10 lb/A) gave excellent initial control of Trichodorus christiei and prevented the rapid recovery expected of the species following nematicide applications. No T. christiei were recovered for three months after Ambush and MoCap treatments; after four months there was 4 percent recovery of T. christiei (5 nematodes/150 ml soil) in these plots. Population levels of T. christiei, at the end of three months, was 20 per cent of normal following Dasanit applications, 60 percent at the end of four months. Thimet (10 lbs/A) and Zinophos (16 lb/A) were 50 percent effective in controlling this nematode at the end of three months, populations returned to normal in the fourth month. Ambush and MoCap at rates applied were phytotoxic, the other materials did not improve chrysanthemum yield. Where planting was delayed for a month following treatment, only MoCap was phytotoxic in natural soil. In previously steamed soil, Ambush, Zinophos Thimet (4.5 lb/A) and Dasanit, as well as MoCap, were phytotoxic.

4.0261, BIOLOGY AND CONTROL OF INSECTS AND RELATED PESTS ON ORNAMENTAL PLANTS
S.L. POE, Gulf Coast Agric. Expt. Sta., *Bradenton, Florida* 33505 (FLA-GC-01353)

OBJECTIVE: Determine seasonal history, biology, ecology, and prevalence of insects and related pests infesting ornamental plants. Develop an efficient and effective program for control.

APPROACH: Investigate the biology and ecology of the important insects and mites destructive to ornamental plants and nursery products. Insecticides and miticides will be evaluated for effectiveness and phytotoxicity.

PROGRESS: Dyfonate 10 g at 25 grams per 5 gallon container reduced the population of the oleander scale, Phenocaspis corkerelli (Cooley) on Bird-of-Paradise, Strelitizia reginae. All new foilage has remained free from the scale for six months.

4.0263, CONTROL OF WEEDS IN WARM SEASON TURFGRASSES WITH HERBICIDES

G.C. HORN, Univ. of Florida, Agricultural Experiment Sta., *Gainesville, Florida* 32601 (FLA-HT-01282)

OBJECTIVE: Evaluate herbicides and develop more effective methods of controlling weeds in turfgrasses.

APPROACH: New temporary soil fumigants will be evaluated to determine their effectiveness for control of weeds that cannot be selectively controlled in turf. Preemergence weed control will include evaluation of new herbicides that have preemergence activity. Postemergence weed control will include evaluation of new herbicides that have activity on established weeds. Non-selective herbicides will be evaluated at different rates and frequencies of application for control of weeds that cannot be selectively controlled in turf. Evaluations will be made visually estimating the degree of control. Turf tolerance will be determined by using rates 2 and 4 times that usually necessary for satisfactory weed control and evaluated by visually estimating the degree of discoloration and thinning.

PROGRESS: Tifdwarf bermudagrass has become very popular for putting green use in Florida during the past 5 years. Weeds have become a major problem in some of these greens. Complaints of damage to Tifdwarf from herbicides, recommended for other bermudas, used for weed control prompted this study. A 5 year old Tifdwarf green, in excellent condition, was used to determine phytotoxic effects of 20 herbicides at recommended rates and twice recommended rates. Herbicides and rates used in 0ai/A, in parentheses, were atrazine (1, 1/2), simazine (1, 1/2), Prometryne (1, 1/2), DSMA (6,4,2), MSMA (6,4,2,1), 2, 4-D-amine (2,1, 1/2), 2,4-D-butyric (2,1, 1/2), Silvex (2,1, 1/2), ASAK (36,18, 9), Herban (6,3,1-1/2), Banvel-D (1, 1/2, 1/4), Treflan (8,4,2), Betasan (36, 18), Dacthal (48,24), TOK (8,4,2), Tenoran (12,6), Sindone (16,8), Sindone B (16,8), DSMA 2,4-D-amine (4, 1/2 and 2, 1/2 resp.) and MSMA 2,4-D-anime (4, 1/2). Each material was applied without oil and with 2 gpa of sunspray 11EL oil. Results - Simazine, atrazine and prometryne were very toxic, at both rates used, for two months but plots did recover. These materials should not be used on Tifdwarf bermudagrass. DSMA and MSMA at higher rates produced phytotoxic effects that lasted about 7 days and then looked better than the checks.

4.0264, FUMIGANTS AND DIPS FOR CONTROL OF INSECTS

L.C. KUITERT, Univ. of Florida, Agricultural Experiment Sta., *Gainesville, Florida* 32601 (FLA-EY-01315)

OBJECTIVE: Evaluate improved methods of insect control on ornamental plants and subtropical fruits by use of fumigants and insecticidal dips.

APPROACH: Various fumigants and insecticides will be used at different concentrations to determine their effectiveness in controlling insect pests. Studies to determine phytotoxic effect of these materials on living plants and injury to subtropical fruits when controlling insect pests.

PROGRESS: In cooperation with the Division of Plant Industry insecticidal treatments including 2 drenches, 9 dips and 4 granular formulations were applied to calamondins infested with coffee root mealybugs, Geococcus coffeae. The infestation was located at Ustler's Nursery, Apopka. The infested plants to be treated were growing in 2" pots. Plants were placed in plastic trays (12 plants/treatment) and the tray placed in the dip treatment so the soil surface was below the surface of the insecticide treatment for 5 minutes, removed and allowed to drain before plunging in steam sterilized media. The treatments and the Active Ingredients (ounces) per 100 gallons included, Bayer 68138 (6), Geigy 13005 (14.7), DiSyston (16), Azodrin (12.8), Zinophos (8), Zinophos (16), phorate (16), DuPOnt 1410 X 90W 8 and Dasanit (16). Azodrin, Zinophos, lannate and phorate gave excellent control after 4 weeks. The drench treatments consisted of zinophos and Dasanit used at the rate of 8 oz per 15 gallons and applied to 80 sq. ft. of bed with plants in 2 and 4 inch pots plunged in media. Treatments were applied with a hose-on applicator and then watered in. These plots have received five applications at 2 week intervals. The mealybug populations have been greatly reduced with only an occasional live specimen being found. The test is still in progress. This method is much simpler than the dip method and could be accepted by the nursery man. The granular treatments consisting of lannate, carbofuran, Dasanit and phorate were not effective.

4.0265, CHEMICAL WEED CONTROL FOR COMMERCIAL VEGETABLE PRODUCTION

S.J. LOCASCIO, Univ. of Florida, Agricultural Experiment Sta., *Gainesville, Florida* 32601 (FLA-VC-00591)

OBJECTIVE: Determine effectiveness of certain chemical preparations for control of weeds in vegetable production on sandy soil.

APPROACH: Testing of materials to which crops have wider tolerance ranges than the present recommended chemicals; herbicides which can be used postemergence on crops where only preemergence weed control is now recommended or vice versa; chemicals which are better suited to crops such as eggplant, lettuce, cucumber, squash, and okra where there are presently no weed control recommendations. Herbicides which are more specific for certain hard to kill weeds like Bermudagrass, torpedograss and nutgrass; better formulations of our present materials, especially those which will reduce solubility or retain materials against leaching; chemicals which act as nematocides and soil fungicides but also have herbicidal properties; chemicals which are less volatile and less dependent on soil moisture for effective weed control.

PROGRESS: Twenty-four herbicide treatments were evaluated on Charleston Gray watermelons in the spring of 1969. Treatments that provided the best weed control throughout the season were 1 pound per acre nitralin surface applied and water into the soil with over-head irrigation at the rate of 1 inch per acre, 1 pound per acre terbacil surface applied and preplant incorporated. Maximum fruit yields were obtained from plots treated with .75 and 1.5 pounds per acre paraquat applied delayed preemergence (before emergence of the watermelon seedlings), preemergence applications of 1 pound per acre nitralin surface applied or watered in. One pound per acre terbacil surface applied or preplant incorporated. Lower rates of terbacil from .125 pound to .5 pound per acre surface applied or preplant incorporated did not provide adequate weed control.

SUPPORTED BY Florida State Government - Tallahassee

4.0266, REDUCTION OR ELIMINATION OF PESTICIDE RESIDUES ON FOOD AND FEED PRODUCTS

N.P. THOMPSON, Univ. of Florida, Agricultural Experiment Sta., *Gainesville, Florida* 32601 (FLA-FS-01242)

OBJECTIVE: Study food and feed products with respect to: location and persistence of pesticide residues in market products, effects of pesticide residues on quality characteristics, development of commercial marketing and processing techniques for detection, removal and/or neutralization of pesticide residue effects.

APPROACH: Florida will contribute under objective 1a and 1c by studying persistence and methods of reducing excessive residues of DDT, endrin, toxaphene and parathion on leafy crops such as cabbage and celery at a marketable stage of development.

PROGRESS: Celery ribs painted with an ethanol solution of Parathion-S were frozen after intervals of 3 hrs. 1, 2, 3 and 5 days. Frozen rib pieces were cross-sectioned at 16 u. Sections were mounted on glass microscope slides, freeze dried, coated with Kodak NTB - 2 liquid photographic emulsion and placed in a freezer for 30 days. The emulsion was developed and coverslips were mounted over sections. Comparison, by oil emersion phase contrast microscopy, of the emulsion layer and the section showed silver grains above epidermal areas as well as above outer cortical cells indicating that parathion applied in this way does not all remain on the cuticle. No specific accumulation, such as in vascular tissue, has been observed. The internal appearance of radioactivity could explain the difficulty of parathion removal with surface washing procedures.

4.0267, CENTRALIZED PESTICIDE RESIDUE INVESTIGATIONS OF SOUTHERN AGRICULTURAL EXPERIMENT STATIONS

C.H. VANMIDDELEM, Univ. of Florida, Agricultural Experiment Sta., *Gainesville, Florida* 32601 (FLA-FS-01202)

OBJECTIVE: Develop pesticide residue research center with emphasis on chemical and instrumental methodology. After analytical load has been determined, metabolic fate studies initiated with various plants.

APPROACH: Coordinated regional residue problems are undertaken with the prior approval of the technical committee. The centralized laboratory furnishes to the other residue laboratories in the region a standardized sampling, extraction and cleanup procedure to follow. The central laboratory helps to evaluate lab to lab variation in analytical procedures by analyzing one sample field replication from each state experiment. Referee samples are prepared at the central laboratory for distribution to and analysis by all the participating state laboratories. These referee studies aid in the elucidation of laboratory variation in sample cleanup and between various types of gas chromatographic detectors.

PROGRESS: Develop sensitive and reliable analytical procedures for analyses of pesticide residues and obtain information on possible uptake of chlorinated hydrocarbon pesticides by crops growing in contaminated soils. Exchange collaborative samples, determine effect of peanut oil in samples on accuracy of electron capture gas chromatographic analyses for dieldrin residues. Advantages and disadvantages of various commercially available GLC detectors investigated by collaborative exchange of common samples. Oil content in sample can have a significant effect in depressing dieldrin values compared to samples containing no oil. Data indicates that sodium thermionic detector is superior to flame photometric detector in terms of sensitivity and noise. Thermionic detector was inferior to photometric detector in selectivity, accuracy, precision, drift and dynamic range. Thermionic detector required more attention and was more erratic than photometric detector. Peanuts grown on some soils containing as low as 0.1 ppm dieldrin can become contaminated with residues that exceed the FDA action level. All cooperators experienced analytical difficulties with oil in samples.

SUPPORTED BY U.S. Dept. of Agriculture

4.0268, PESTICIDE RESIDUES IN AGRICULTURAL COMMODITIES AND ENVIRONMENTS

C.H. VANMIDDELEM, Univ. of Florida, Agricultural Experiment Sta., *Gainesville, Florida* 32601 (FLA-FS-01469)

OBJECTIVE: New or improved extraction, cleanup and analytical techniques; preplanned cooperative regional experiments; fate of pesticides and toxic metabolites in plants, animals and soils; disappearance rates of pesticides from commodities and environments.

APPROACH: The central laboratory will initiate basic studies on sample extraction, cleanup and analytical techniques for pesticides in cooperation with other interested state laboratories in the region. Cooperative field experiments between the central laboratory and other laboratories will be designed to solve pesticide residue problems of regional interest. This laboratory will investigate the movement, accumulation and metabolic fate of several pesticides in higher plants. The central laboratory will continue to conduct studies on the disappearance rates of various pesticides on commercial crops.

PROGRESS: An alkali flame detector with a KBr pellet was evaluated as to its response to several carbamate pesticides and compared to an AFID with a Rb(2)SO(4) pellet. The flame photometric detector was evaluated on various citrus fruit previously treated in the field with a promising phosphorodithioate called Torak. This detector was observed to have distinct advantages over the thermionic detector, particularly on uncleaned citrus extracts. The effects of dieldrin and DDT on the photosynthetic rate of Chlorella pyrenoidosa were measured. Initiated work with human tissue cultures with the ultimate goal of observing changes in cellular biochemistry as influenced by subtoxic levels of pesticides. The uptake of 2,4-D-C from liquid nutrient solution into corn, peanuts and soybeans was investigated by autoradiography, TLC and liquid scintillation. In corn roots, radioactivity appeared at Rf .35 in addition to .80 which corresponds 2,4-D-C using 8:1:1 isopropanol:ammonia:water as the eluting solvent on aluminum oxide plates.

4.0269, ECOLOGICAL RECORDS ON ELGIN AFB RESERVATION

D.B. WARD, Univ. of Florida, Agricultural Experiment Sta., *Gainesville, Florida* 32601 (FLA-BT-01410)

OBJECTIVE: Measure the effects on the surrounding vegetation of an Air Force program of testing biological weapons, using active herbicidal and bacterial agents.

APPROACH: A series of transects have been established at varying distances from the test area. Frequency of occurrence of species of vascular plants is measured with replication permitting quantitative measurement of significance of any observed fluctuations in number of individuals intercepted by transects, thus determining if spray driftage from test area has significantly affected population sizes of vascular plants in surrounding area.

PROGRESS: A pre-existing Air Force program on the Eglin AFB Reservation, Florida, of testing spray equipment designed to apply military chemical and biological agents by aerial means, has given rise to the possibility that the testing program is affecting the biota outside the test area. A program of sampling the vegetation by means of nested transects, and subsequent analysis, gave little indication that the effects of spray driftage were of effect in reducing the frequency of any plant species. A supporting program was begun of documenting the present flora of the Reservation, as a base for understanding effects of future Air Force activities.

4.0270, CHEMICAL WEED CONTROL FOR COMMERCIAL VEGETABLE PRODUCTION

J.R. SHUMAKER, Florida Agric. Expt. Station, *Hastings, Florida* (FLA-PR-00591)

OBJECTIVE: Determine effectiveness of certain chemical preparations for control of weeds in vegetable production on sandy soil.

APPROACH: Testing of materials to which crops have wide tolerance ranges than the present recommended chemicals; herbicides which can be used postemergence on crops where only preemergence weed control is now recommended or vice versa; chemicals which are better suited to crops such as eggplant, lettuce, cucumber, squash, and okra where there are presently no weed control recommendations. Herbicides which are more specific for certain hard to kill weeds like Bermudagrass, torpedograss and nutgrass; better formulations of our present materials, especially those which will reduce solubility or retain materials against leaching; chemicals which act as nematocides and soil fungicides but also have herbicidal properties; chemicals which are less volatile and less dependent on soil moisture for effective weed control.

PROGRESS: CABBAGE - Winter weed control trials consisting of preplant, soil incorporated trifluralin and postplant CDAA CDEC, CDEC, DCPA, nitrofen and propachlor were conducted with direct seeded and transplanted cabbage. Chickweed, Stellaria media, and seedling dock, Rumex hastatulus, were the most numerous weeds. DCPA at 10.5 A/A (lbs.) was superior to other herbicides tested. Good weed control was observed following the use of trifluralin at 1.0 A/A (lbs.) and CDAA

CDEC, both at 3.0 A/A (lbs.). Propachlor at 3.9 A/A (lbs.) were slightly less effective. All herbicide treated plots produced significant increases in yields over the uncultivated control in the direct seeded cabbage. POTATOES - Preemergence application of 17 herbicide treatments gave variable weed control. Metaburon at 3.0 and 2.0 A/A (lbs.), linuron at 2.0 and 1.0 A/A (lbs.), Maloran at 2.0 and 1.0 A/A (lbs.) and Lasso at 4.0 A/A (lbs.) gave good control of weeds and were superior to other herbicides tested. DCPA at 10.5 A/A (lbs.), Lasso at 2.0 A/A (lbs.), DNBP at 3.0 A/A (lbs.), EPTC at 6.0 and 4.0 A/A (lbs.) and nitrofen at 4.0 A/A (lbs.) were rated slightly less effective. Trifluralin incorporated into the soil after planting reduced yields. Smartweed, Polygonum pensylvanicum, interfered the most with harvest operations.

SUPPORTED BY Florida State Government - Tallahassee

4.0271, BIOLOGY AND CONTROL OF INSECTS AND RELATED PESTS ON ORNAMENTAL PLANTS
R.M. HARANOWSKI, Sub Tropical Agric. Expt. Sta., *Homestead, Florida* 33030 (FLA-SB-01353)

OBJECTIVE: Determine seasonal history, biology, ecology, and prevalence of insects and related pests infesting ornamental plants. Develop an efficient and effective program for control.

APPROACH: Investigate the biology and ecology of the important insects and mites destructive to ornamental plants and nursery products. Insecticides and miticides will be evaluated for effectiveness and phytotoxicity.

PROGRESS: Six varieties of chrysanthemums were used to obtain data on phytotoxicity and efficacy of three formamidine acaracides which were applied at 4 and 8 oz of the formulations per 100 gal at 7 and 14 day intervals. Foliage of 'White' and 'Yellow Iceberg,' 'Bluechip,' 'Shasta' and 'Beauregard,' but not 'Pinocchio,' showed interveinal yellowing and marginal chlorosis in plots treated with EP-333 and EP- 334. Injury from EP-332 was not noted until flowers were cut when yellowing was observed on older leaves of 'Yellow' and 'White Iceberg.' EP-332 did not control the two spotted spider mite. EP-333 and EP-334 did provide a measure of control but higher dosages would probably be needed for good consistent control. Morocide, Morestan and Kelthane were applied to roses with and without M-45 and Daconil to determine if these compounds had any effect on the acaracides. Neither fungicide affected control by the miticides. Three weekly applications of TH367- I, TH427-I, GA490, GA494, GS19849, Morocide, Carzol, CP49674 and Chloropropylate were applied to roses infested with a very high population of two-spotted spider mites that had shown a high degree of resistance to most compounds. Only Morocide, GA490, GA494, GS19849 and TH397-I reduced the number of mites to less than 10 per leaf compared to 50 on check plots. In other tests, dicofol, Galecron, Dessin and Morestan were effective mite controls.

SUPPORTED BY Florida State Government - Tallahassee

4.0272, CHEMICAL WEED CONTROL FOR COMMERCIAL VEGETABLE PRODUCTION
R.W. HARKNESS, Sub Tropical Agric. Expt. Sta., *Homestead, Florida* 33030 (FLA-SB-00591)

OBJECTIVE: Determine effectiveness of certain chemical preparations for control of weeds in vegetable production on sandy soil.

APPROACH: Testing of materials to which crops have wider tolerance ranges than the present recommended chemicals; herbicides which can be used postemergence on crops where only preemergence weed control is now recommended or vice versa; chemicals which are better suited to crops such as eggplant, lettuce, cucumber, squash, and okra where there are presently no weed control recommendations. Herbicides which are more specific for certain hard to kill weeds like Bermudagrass, torpedograss and nutgrass; better formulations of our present materials, especially those which will reduce solubility or retain materials against leaching; chemicals which act as nematocides and soil fungicides but also have herbicidal properties; chemicals which are less volatile and less dependent on soil moisture for effective weed control.

PROGRESS: Previous work has shown diphenamid is an effective pre- emergence herbicide for direct-seeded tomatoes, but three experiments, each of which had several inches of rain soon after application, showed it to be nearly ineffective. Under these conditions, planavin, Niagara 20439, amiben ester (65-81B) and Lasso gave good control of most weeds. Lasso caused such severe stunting that it would be unsatisfactory for tomatoes. Planavin and the amiben ester gave excellent control of purslane while the others were less effective. Amiben was nearly ineffective with wild lettuce (Lactuca sp.) and planavin was only partially effective. Bermuda grass and a few other weeds seemed to resist all herbicides. Prickly poppy is particularly resistant to all herbicides used on tomatoes. High rates of planavin (2 lb/A) and amiben ester (4 lb/A) caused a slight reduction of tomato germination in some experiments, but not in others. Niagara 20439 should be tested further.

SUPPORTED BY Florida State Government - Tallahassee

4.0273, PRELIMINARY EXPLORATORY RESEARCH AT THE SOUTH FLORIDA FIELD LABORATORY
P.H. EVERETT, South Florida Field Laboratory, *Immokalee, Florida* 33934 (FLA-SF-00001)

OBJECTIVE: Conduct preliminary investigations on vegetable crops.

APPROACH: Exploratory research experiments will be conducted on tomatoes, watermelon and vegetable crops with respect to nutrition, pest control, variety trials and disease control.

PROGRESS: Effect of lime on Fusarium wilt of watermelons.--Four lime and/or calcium materials at 4 rates were compared factorially for their effectiveness in reducing damage caused by Fusarium wilt. The amount of wilt decreased and the yield increased as the rate increased from no lime to 6 tons/acre. Calcic limestone was the most effective and gypsum the least, with dolomite and a 1:1 mixture of calcic and domolite being intermediate. Effect of Pinoline 1919 on tomato yields.--'Pinoline' is derived from terpene polymers and is a tradename of Miller Chemical and Fertilizer Co. Pinolene at 6 concentrations: 0, 0.5, 1.0, 2.0, 3.0 and 5.0% (in water) were applied at both 7 and 14 day intervals to tomatoes. The 7 day plots received 6 applications and the 14 plots received 3 applications. Phytotoxic symptoms were evident on the foliage of plants sprayed with the 5.0% concentration at both the 7 and 14 day intervals. However, this damage to the foliage was not reflected in the yield since there was no significant difference in yield due either to concentration or application interval.

SUPPORTED BY Florida State Government - Tallahassee

4.0274, CHEMICAL CONTROL OF SCALES AND OTHER INSECTS INFESTING CITRUS
R.F. BROOKS, Citrus Agricultural Expt. Sta., *Lake Alfred, Florida* 33850 (FLA-CS-00835)

OBJECTIVE: Determine most effective and economical scalicides, and determine insecticides necessary to control other insects of major importance.

APPROACH: Where insecticides are tested in the field, treatments are replicated three to four times. Factors considered include dosage, phytotoxicity, timing of application in relation to effect on trees and fruit quality and compatibility with other materials.

PROGRESS: Various insecticides were evaluated for control of scale insects, whiteflies, and aphids. Glover and Purple Scale Control.-- Promising materials were Lannate, Furadan, Lannate-oil, Velsicol VCS- 506, Monitor, and ethion-oil. Chaff Scale Control.--Effective materials were Furadan, Lannate, Velsicol VCS-506, Monitor, Union Carbide 34096, ethion-oil, and oil emulsion. Yellow Scale Control.--Effective materials were Lannate, Furadan, Velsicol VCS-506, Monitor, ethion-oil, and emulsion. Citrus Snow Scale Control.--Promising materials were ethion, carbophenothion, parathion, malathion, Lannate, Velsicol VCS-506, Monitor, Supracide, Monitor-oil, Hercules 14503, Thompson-Hayward 346-I, and dioxathion. Citrus Whitefly Control.--Effective materials were Union Carbide 34096, Furadan, and Monitor. Aphid Control.-- Promising materials were oxydemeton-methyl, Bidrin, Thompson-Hayward 346- I, and Temik.

SUPPORTED BY Florida State Government - Tallahassee

4.0275, CONTROL OF POSTHARVEST CHEMICAL RESIDUES IN OR ON CITRUS FRUITS
F.W. HAYWARD, Citrus Agricultural Expt. Sta., *Lake Alfred, Florida* 33850 (FLA-CS-01146)

OBJECTIVE: Determine effect of treatment conditions on chemical residues from citrus packinghouse processes and develop methods of process control that will insure maximum effectiveness of treatment within legal chemical residue standards.

APPROACH: Effect of treatment conditions on residues will be studied first. Some of these variables will be time of exposure to treatment, temperature, concentration of active agent, pH of solution, ventilation of fruit container, and species or variety of citrus fruit. Chemical residue determinations will be primary consideration, but measurements of effectiveness of treatment will be made. Following determination of effect of treatment conditions on residue, sets of conditions will be chosen, and checked for effectiveness and level of residue.

PROGRESS: Simulated, in-transit fumigation of citrus fruits with 2-aminobutane was studied to determine the effects of treatment conditions on residues of this fungicide. Experiments were made with 'Hamlin' and 'Valencia' oranges, 'Dancy' tangerines and 'Temple'. Residues increased with time, temperature, and dosage of 2-aminobutane. Heavy loads of fruit in the fumigation cabinet delayed the buildup of residues. Residues can be kept within the legal tolerance of 20 ppm by proper selection of treatment conditions. At higher temperatures, dosage and length of fumigation period offer the best method of controlling residues. At lower temperatures there is little tendency to exceed the legal tolerance but dosage of 2-aminobutane should be controlled.

4.0276, CHEMICAL CONTROL OF MITES ATTACKING CITRUS
R.B. JOHNSON, Citrus Agricultural Expt. Sta., *Lake Alfred, Florida* 33850 (FLA-CS-01457)

OBJECTIVE: Establish better control of citrus rust mite, citrus red mite, and Texas citrus mite.

APPROACH: Potential acaricides will be compared with standard acaricides in grove trials. Dosage, chytotoxicity and compatibility with other compounds will be determined.

PROGRESS:

SUPPORTED BY Florida State Government - Tallahassee

4.0277, WEED CONTROL IN CITRICULTURE
R.L. PHILLPS, Citrus Agricultural Expt. Sta., *Lake Alfred, Florida* 33850 (FLA-CS-00945)

OBJECTIVE: Devise effective, safe, and practical methods of using herbicides for controlling weeds in and adjacent to citrus plantings and sites. Study the effects of herbicides on citrus trees.

APPROACH: Control of weeds in groves and nurseries -- Field trials will be established to evaluate the effectiveness of diuron, simazine, and EPTC on control of annual weeds in groves nurseries. Repeated low rates of dalapon will be studied for perennial grass control in groves. Control of aquatic and ditchbank weeds in coastal groves -- Several commercially available soil steritant and growth-regulator type herbicides will be evaluated for control of submersed and emergent aquatics and ditchbank vines, brush and perennial grasses in coastal grove ditches. Residual effects of annual or semi-annual applications of herbicides on tree growth and yield will be studied. A continuous program of screening new herbicides will be conducted.

PROGRESS: Dichlobenil has continued to give excellent control of a wide number of weeds. After 2 applications the first year, only 1 application per year has been required for satisfactory control. Results with diuron were also favorable but control did not last as long. Control with terbacil was not satisfactory in some cases because tolerant weeds were present. The addition of paraquat increased the effectiveness of diuron and terbacil where larger weeds were present when applied. Treflan gave excellent control of annual grasses but tolerant weeds were not affected in many plots. Several new herbicides were tested. GS-14254 and VCS-438 showed promise for use in citrus groves because of their long-lasting effects on weed growth and their low toxicity to citrus trees. Vine control studies were made using growth regulators, preemergence herbicides and contact herbicides. In general, 2,4,5-TP was the most effective phenoxy herbicide tested. The addition of surfactants and non-phytotoxic oils increased its effectiveness. Casoron was the most effective preemergence herbicide tested, followed by the triazines. Contact herbicides resulted in good control with frequent applications.

SUPPORTED BY Florida State Government - Tallahassee

4.0278, PETROLEUM OILS AS CITRUS TREE SPRAYS IN FLORIDA
W.A. SIMANTON, Citrus Agricultural Expt. Sta., *Lake Alfred, Florida* 33850 (FLA-CS-01252)

OBJECTIVE: Relate physical and chemical properties of petroleum oil to effectiveness in control of insects, mites and disease, and to phytotoxic effects. Determine if oils of specific properties can be used advantageously on Florida citrus. Improve methods for determining oil deposits obtained with field applications.

APPROACH: Twenty-five specially prepared oils of known properties and 30 commercial spray oils will be evaluated by laboratory tests. Dosage-mortality data will be obtained against citrus red mite eggs and Florida red scale. Certain of the oils will be evaluated for phytotoxic effects as indicated by transpiration rate of sprayed seedlings. Certain oils will be applied to field plots to study effect on tree and fruit.

PROGRESS: The 21 samples of citrus spray oils picked up by State Department of Agriculture inspectors in 1968 were subjected to laboratory tests to determine conformance to specifications developed under this project. Of 2 sample oils apparently intended as type FC 412-66, both failed to meet specifications. Of 19 samples oils apparently intended as type FC 435-66, 10 met specifications and 9 did not comply. The most common fault was a departure in distillation characteristics. Three of the 21 samples failed because of low unsulfonated residue and 1 also failed because of low gravity. The test results were relayed to the State Chemist. On June 13 the Pesticide Technical Committee for the State Department of Agriculture held a hearing on a proposal to include the spray oil specifications from this project in official regulations. Assistance was given the State Chemist in equipping his laboratory for spray oil testing and in providing reference standards. Many inquiries about the field use of spray oil were handled: however, fewer problems concerning spray oils were encountered than in prior years.

4.0279, PRELIMINARY RESEARCH ON CUCURBITS AND FRUIT CROPS
J.M. CRALL, Watermelon & Grape Inves. Lab., *Leesburg, Florida* 32748 (FLA-WG-00001)

OBJECTIVE: Investigate new problems in the production of cucurbits and fruit crops in Florida.

APPROACH: Preliminary studies will be made on bacterial diseases of watermelon; these will include identification of the causal organisms, conditions favoring development of the diseases they cause, establishment of host range, and methods of control. Preliminary studies on grapes will include trials on varieties, nutrition, herbicides, hormones, rootstocks, and trellising. Peach varieties will be tested.

PROGRESS: The value of a protein-base foam and Hotkaps for cold protection of watermelon seedlings was investigated. Although minimum temperatures under both foam and Hotkaps were 3 to 16 F higher than minimum ambient temperatures, there were no differences in either early or total yields for planting dates or cold protection treatments. Ethrel caused the development of hermaphrodite flowers at an earlier than usual stage of growth and decreased the ratio of male to hermaphrodite flowers in cucumber, pumpkin, squash, and cantaloupe, but not in watermelon. Soil applications of Emjeo corrected Mg deficiency symptoms in grape leaves, and increased Mg content of petioles and soluble solids content of berries, but decreased plant vigor and fruit yields. Pruning weights were higher from vines on Munson trellis than from those on either 4-Wire Horizontal (4WH), or

Geneva Double Curtain (GDC) trellises, but fruit yields were highest on 4WH, intermediate on GDC, and lowest on Munson trellises. Weed control without phytotoxicity was best in mature vineyard with Karmex, Casoron, and Simazine at 6 lb. (active ingredient per acre); in young vineyard with Simazine, Casoron, and Planavin at 4 lb.; and in a cutting nursery with a Ramrod-Atrazine mixture at 5 lb.

SUPPORTED BY Florida State Government - Tallahassee

4.0280, CHEMICAL CONTROL OF SOIL FUNGI, NEMATODES, AND WEEDS AFFECTING WATERMELONS
N.C. SCHENCK, Watermelon & Grape Inves. Lab., *Leesburg, Florida* 32748 (FLA-WG-01151)

OBJECTIVE: Effect of soil fumigants on soil fungi, nematodes, weeds, and crop response.

APPROACH: Fumigants will be applied to land intensively cropped in watermelons. Both Fusarium wilt resistant and susceptible varieties will be planted in treated areas. Populations of Fusarium sp., Rhizoctonia sp., Pythium sp., other soil fungi, plant parasitic nematodes, and weeds will be estimated. Stand counts, vigor ratings, and yield will be used to evaluate crop response.

PROGRESS: Vorlex adequately controlled Fusarium wilt in soil moderately infested with Fusarium oxysporum f. niveum but it was phytotoxic to watermelons (35 gallons per acre broadcast). Thirty-two days after treatment, seedling stands of both Charleston Gray (wilt resistant) and Florida Giant (wilt susceptible) varieties were lowest in Vorlex-treated areas. Differences among chemical treatments in final stands of Charleston Gray were not statistically significant, but final stand of Florida Giant was significantly highest in Vorlex-treated soil. Vorlex-treated soil consistently had the lowest soil fungus populations and yielded no Fusarium colonies throughout the season. Total fungus populations were usually highest in Busan-treated soil, resulting from an apparent stimulation of certain species of Penicillium. A total of 24 different genera and species of fungi were isolated from Busan-treated soil while only 12 different fungus species were obtained from Vorlex-treated soil. Charleston Gray variety had the highest yields and differences among chemical treatments were not significant. Florida Giant yields were exceedingly low in Busan-treated (92.3 CWT/acre) and untreated soils (73.2 CWT/acre) but were also below average in Vorlex- treated soil (160.3 CWT/acre).

4.0281, CHEMICAL CONTROL AND PHYSICAL AUTECOLOGY OF INSECTS ATTACKING CIGAR-WRAPPER TOBACCO
W.B. TAPPAN, North Fla. Agric. Expt. Sta., *Quincy, Florida* 32351 (FLA-NF-01214)

OBJECTIVE: Evaluate chemicals for control of insects attacking cigar-wrapper tobacco; measure some effects of air and soil temperature and/or humidity upon insect pests of cigar-wrapper tobacco and insecticides used for control.

APPROACH: Screening of new materials. Determine efficiency of insecticides on control of insects and their effects on yield, quality, and other characteristics. Instrumentation of experiments to determine effects of temperature and/or humidity on individual insect pests and insecticides.

PROGRESS: New insecticides found effective for control of the following insects were: Green Peach Aphid-Azodrin, Furadan, and Lannate; Budworm-Azodrin, Furadan, GS-13005, Lannate, and Thuricide 90 TS spray; Cabbage Looper-Azodrin, Furadan, GS-13005, and Lannate; Flea Beetle- Azodrin, Furadan, GS-13005, Lannate, and Parathion Thuricide 90 TS spray; Cutworms-Dylox bait; and Flase Chinch Bug-TH-427-I and Thuricide 90 TS spray. Phytotoxicity with Azodrin and Fundal eliminates these materials for use on wrapper tobacco. Crop evaluation of Furadan phytoxicity indicates this material can be used without commercial objection. Symptoms of veinbranding virus infection appeared in plants 8 to 12 days after exposure to infected aphids. Yields, leaf quality, and crop value were improved by Lannate and Thuricide 90 TS spray. Neither Lannate nor TH-427-I caused any objectionable off-flavor in cigars manufactured from treated cigars. Uptake of Endrin and DDT from cigar-wrapper tobacco soils by turnips was minimal.

SUPPORTED BY Florida State Government - Tallahassee

4.0282, CHEMICAL CONTROL OF NEMATODE ROOT ROT COMPLEX OF SHADE-GROWN TOBACCO
W.B. TAPPAN, North Fla. Agric. Expt. Sta., *Quincy, Florida* 32351 (FLA-NF-01074)

OBJECTIVE: Not Provided

APPROACH: Not Provided

PROGRESS: Vorlex at 7 and 20 gallons per acre effectively reduced weed growth and the number of transplants lost to fungus rots. All treatments except Dasanit and Lannate at low rates reduced the number of plants with physiological wilt symptoms. Bayer 68138, Dasanit, Furaden, and Vorlex effectively reduced nematode numbers in the roots. Florida 17 apparently is more sensitive to nematode attack than Florida 15 since treatment responses were more pronounced. Plant growth, yield, and crop value were increased by all treatments. Coarse root indices were reduced by all treatments except the low rate of Bayer 68138 indicating some slight root injury from the compound. Phytotoxicity from Furadan was light indicating the material may be commercially acceptable for use on some varieties. None of the treatments had any effect on weather fleck. Dasanit, Furadan, and Temik increased soil nitrogen conversion in the field and growth chamber studies.

SUPPORTED BY Florida State Government - Tallahassee

4.0283, ABSCISSION OF TREE FRUITS
UNKNOWN, North Fla. Agric. Expt. Sta., *Quincy, Florida* 32351 (FLA-NF-01301)

OBJECTIVE: Effect of new chemicals on induction or prevention of abscission of both young and old fruit; anatomical and biochemical changes occurring during development of both naturally and chemically- induced fruit abscission; physiological effect and phytotoxicity of selected chemicals on trees under field conditions.

APPROACH: Chemicals will be screened to promote and prevent abscission of tree fruits. Screening trials will involve both whole trees and detached fruits, and an attempt will be made to determine the anatomical and biochemical changes induced in the tissue by the active compounds during abscission. Isolation and characterization of the compounds produced as a result of metabolism of the abscission influencing compound will be attempted to determine the identity of the actual compound influencing abscission.

PROGRESS: Development of a chemical means of thinning peach fruit is imperative if the industry is to continue. Replicated single-tree plots of Armgold and Maygold peaches were sprayed with several chemicals as full bloom and post-bloom sprays. Full bloom sprays of Ethrel at 100 ppm on Armgold and 300 ppm on Maygold gave adequate thinning but not as good as the 500 ppm rate. Fruit size was greatly increased where the thinning was the best. Post-bloom application of 400 ppm of 3-CPA when seed length was 9-10 mm resulted in the most efficient thinning of any 3-CPA treatments.

SUPPORTED BY Florida State Government - Tallahassee

4.0284, CHEMICAL WEED CONTROL FOR COMMERCIAL VEGETABLE PRODUCTION
W.T. SCUDDER, Central Fla. Agric. Expt. Sta., *Sanford, Florida* 32771 (FLA-CF-00591)

OBJECTIVE: Determine effectiveness of certain chemical preparation for control of weeds in vegetable production on sandy soil.

APPROACH: Testing of materials to which crops have wider tolerance ranges than the present recommended chemicals; herbicides which can be used postemergence on crops where only preemergence weed control is now recommended or vice versa; chemicals which are better suited to crops such as eggplant, lettuce, cucumber, squash, and okra where there are presently no weed control recommendations. Herbicides which are more

specific for certain hard to kill weeds like Bermudagrass, torpedograss and nutgrass; better formulations of our present materials, especially those which will reduce solubility or retain materials against leaching; chemicals which act as nematocides and soil fungicides but also have herbicidal properties; chemicals which are less volatile and less dependent on soils moisture for effective weed control.

PROGRESS: Excellent weed control in direct-seeded cabbage was obtained with both nitrofen and propachlor at 4 lbs. and with CDEC and diphenamid at 6 lbs., applied as over-the-top sprays when the cabbage seedlings with 1 in. tall. Trifluralin at 1 lb., nitralin at 2 lbs., and DCPA at 10 1/2 lbs. gave excellent control of grasses, but poor broadleaf weed control. Only 2 treatments produced crop injury. These were CDAA at 6 lbs. and BAS-2902 at 4 lbs. In a crop residue study with nitralin, radishes, turnips, and carrots were planted following pre-plant incorporated treatments at 0, 2 1/2, 5, and 10 lbs. per acre. All 3 crops accumulated some nitralin in the edible roots at all treatment levels, increasing with both rate of application and exposure time. The check samples from all crops contained less than 0.01 ppm detectable nitralin. In radishes sampled at 46 days after treatment, there was 0.04 ppm residue at the 5 lb. rate and 0.08 at the 10 lb. rate. Turnips at 74 days failed to survive in soil treated with 10 lbs. of nitralin. Carrots at 118 days contained 0.08 ppm from 5 lbs. and 0.24 ppm residue from the 10 lb. treatment.

SUPPORTED BY Florida State Government - Tallahassee

4.0285, THE EFFECT OF HERBICIDES ON GROWTH, YIELD, AND LONGEVITY OF PEACH TREES

J.W. DANIELL, Georgia Agric. Expt. Sta., *Griffin, Georgia* 30212 (GEO-01-0054)

OBJECTIVE: Develop weed control practices and evaluate effects of herbicides on peach production and longevity of trees. Study effects of sodded middles with chemical weed control in rows on the amount of soil compaction from mechanical equipment.

APPROACH: Herbicides will be applied to young and mature trees for seasonal weed control and to study their effects on yield, growth, and longevity of trees. Certain cultural practices will be studied which may be affected by non-harrowing of soil. Studies will be initiated to control problem weeds as they build up from continuous use of a herbicide. Weeds will be controlled with chemicals in rows. About eight feet will be left in the middles in sod which will be mowed for soil compaction studies. Greenhouse and laboratory studies will be used to supplement and implement field tests.

PROGRESS: Experiments were designed to study the cumulative effects of herbicides applied successively for several years on weed control, and on growth and longevity of peach trees. In both 1- and 2- year old orchards, treatments which provided very effective weed control and produced growth of trees equal to or better than the harrow or tree hoe checks were: paraquat 1/2 and 1 lb ai/A; terbacil 2 and 2.5 lb ai/A; incorporated dichlobenil 4 and 6 lb ai/A; simazine 4 and 5 lb ai/A; CP- 44939 3 lb ai/A; diphenamid dinoseb 6 4.5 lb ai/A, and chloropropham dinoseb PPG-124 4 4 1 lb ai/A. Treatments which gave fair weed control, but required an additional treatment with paraquat during the summer to give full season control, were: granular dichlobenil 5 lb ai/A; nitralin 2 and 4 lb ai/A, and W.P. dichlobenil 4 and 6 lb ai/A (not incorporated). There was a significant increase in growth of trees in the simazine, dichlobenil, and nitralin plots when compared to trees in the tree hoe check plots at Ft. Valley, Ga. (2 year). There was no significant differences in growth of trees between treatments at Experiment, Ga. There was no direct phytotoxicity to any trees from the use of the herbicides in these experiments. At the present time, there is no difference between treatments in longevity of trees.

4.0286, WEED CONTROL IN NURSERY STOCK

T.A. FRETZ, Georgia Agric. Expt. Sta., *Griffin, Georgia* 30212 (GEO-01-0056)

OBJECTIVE: Screen and evaluate herbicide-mulch combinations for use on canned and field grown nursery stock. Study the reported increases in persistence of herbicides when incorporated on organic mulches.

APPROACH: Herbicides at several rates will be screened in regard to their effectiveness when used in herbicide-mulch combinations. Screening will be done in pots and evaluation will be determined by the percent kill of selected weed species. Promising combinations will be used on container grown nursery stock.

PROGRESS:

SUPPORTED BY Georgia State Government

4.0287, DEVELOPMENT OF WEED CONTROL PRACTICES ADAPTABLE TO THE PRODUCTION OF GRAIN AND FORAGE CROPS

W.S. HARDCASTLE, Georgia Agric. Expt. Sta., *Griffin, Georgia* 30212 (GEO01028)

OBJECTIVE: Develop weed control practices for corn. Develop weed control practices for other grain and silage crops. Define and attempt to eliminate or minimize toxicological problems incident to the above uses.

APPROACH: The major exploratory phases of the field portion of this study will be located in the Piedmont, with other field testing in the Coastal Plain, Limestone Valley, or Mountain areas, as appropiate. Applications of experimental herbicides, as they become available, will be made to subject crops with research plot sprayers or with commercial equipment adapted to assure precise metering of materials. At least in the exploratory phases, supplemental irrigation will be used as required. Fertilizer and pesticide applications, other than herbicides, will follow standard recommended practices for the crop involved. Laboratory, greenhouse, and environmental chamber effort will be used to supplement and extend field investigations, especially in the areas of residual toxicities.

PROGRESS: Of 92 trials of chemicals, combinations, methods or time of application to heavy stands of sicklepod, common ragweed, common morninggiory, redroot pigweed, cocklebur, prickly sida, and large crabgrass at 2 locations; in preemergence applications to corn, new compounds BAY 86791 at 1/4 to 1 lb/A resulted in poor general broadleaf and good grass control, at high rates sicklepod control was good, but crop damage was excessive; S-6115 at 3 lb/A gave excellent grass and broadleaf control including sida; ACD 15 M was excellent for pigweed and sida control at 1 and 2 lb/A. BAS 2903 at 3-4 lb/A resulted in poor broadleaf and good grass control; SD 15418 at 1-3 lb/A resulted in excellent general weed control at higher rates; VCS 438 at 2-3 lb/A gave poor general broadleaf control at 2 lb/A but good control at 3 lb/A and excellent grass and sida control at both rates, alachlor 2-4 lb/A gave excellent general weed control at high rates; C 6989 3-4 lb/A and C6313 2-4 lb/A resulted in fair broadleaf and good grass control at high rates. 1 1 lb/A equaled weed control from field rates of each compound alone.

SUPPORTED BY U.S. Dept. of Agriculture

4.0288, THE EFFECTS OF A CROP-HERBICIDE ROTATION SYSTEM ON CERTAIN SOIL CHARACTERISTICS

L.S. JONES, Georgia Agric. Expt. Sta., *Griffin, Georgia* 30212 (GEO01051-H)

OBJECTIVE: Study effects of applications of several herbicides to corn, cotton, soybeans and peanuts grown in a 4-year rotation on release and oxidation of sulfur, nitrification, soil organic matter and aggregate relationships. Determine the residual phytotoxicity of herbicides and/or their degradation products.

APPROACH: Field studies on a Tifton loamy sand will be the responsibility of ARS personnel. This personnel will determine if toxic residues occur using bioassay methods. At the Georgia Station, organic matter and aggregate relationships will be determined on soil samples from 0-6' and 7-12' horizons of all plots. Incubation studies for nitrification and for the release and oxidation of sulfur from an amino acid will be conducted.

PROGRESS: Soil samples were collected from the 0-6' and 7-12' horizons of all plots prior to fertilization and application of pesticides and again at harvest time. The initial samples have been analyzed for organic matter, nitrogen, exchangeable calcium, magnesium, and potassium. In addition, a study designed to evalu-

ate the potential microbiological activity of the soils has been conducted. This study indicated that applied ammoniacals oxidized to nitrates at rates in agreement with those found for similar soils. All soil samples have been prepared for analyses for aggregate distribution and stability. Methods suitable for sulfofication and nitrification studies have been selected and these will begin immediately.

SUPPORTED BY U.S. Dept. of Agriculture

4.0289, BIOLOGY AND CONTROL OF INSECT PESTS OF ORNAMENTAL PLANTS

H.H. TIPPINS, Georgia Agric. Expt. Sta., *Griffin, Georgia* 30212 (GEO00154)

OBJECTIVE: Determine important species of insects infesting ornamental plants. Study biology and habits. Develop effective and safe control measures.

APPROACH: The life cycle, habits, and seasonal occurrence of the principal pests will be determined by laboratory rearing and field observations. Practical control measures will be developed. The importance of the biological control will be studied. The phytotoxicity or adverse effects of insecticides on ornamental plants will be determined. Pests to be investigated will include scale insects, lacebugs, and leaf crumplers. Emphasis placed new systemic insecticides.

PROGRESS: In studies on the morphology of scale insects, 20 species of Diaspidini were found to be sexually dimorphic in the second instar. The males possess variously modified ducts which are unlike those of the female in any stage. Morphologically the second instar males show phylogenetic affinities which are often completely obscure in the adult female. A new pest, Maskell scale, was found to seriously affect juniper nursery stock. This scale was controlled with parathion spray and granular dimethoate and Temik in field tests. A new pest, Eusophera sp. -- a lepidopterous borer, was found infesting the roots and lower trunk of magnolia seedlings. Dieldrin sprays were apparently effective in controllig borers in the trunk. In greenhouse tests, several systemic insecticides were highly effective in the control of the azalea leafminer, Di-Syston , Meta-systox and dimethoate applied in irrigation water gave complete control of the leaf miner and prevented reinfestation for nine months. Dimethoate was phytotoxic to one azalea variety. Ninety to 100% control of tea scale was obtained in greenhouse and field tests with systemic insecticides applied to the soil and with oil emulsion sprays. Subfreezing temperatures the day oil sprays were applied to camellia had no adverse effect on the plants.

SUPPORTED BY U.S. Dept. of Agriculture

4.0290, ETIOLOGY OF MERCURIAL PHYTOTOXICITY (FAT LEG) OF SEED PEANUTS

D.K. BELL, Georgia Coastal Pl. Expt. Sta., *Tifton, Georgia* 31794 (GEO-02-0159)

OBJECTIVE: Determine at what stage after treatment phytotoxicity occurs and the effects of temperature and planting depth on the expression of toxicity in three peanut cultivars.

APPROACH: Starr, Florigiant, and Early Runner seed will be treated with various rates of ethylmercury chloride or methylmercury dicyandiamide in dry form or solution. Seed will be incubated at various temperatures and germinated at time intervals during the incubation to note fat leg (toxicity symptom). Seed will be planted at various depths in soil and artificial media to determine effects of planting depth.

PROGRESS: Objectives: Determine the relative susceptibility of seed of Spanish, Runner, and Virginia peanut types to organomercurial toxicity, where in the period from seed treatment through germination the toxic response occurs, and the effect of planting depth on degrees of the toxic response. Cv. Early Runner was most susceptible to excessive organomercury treatment, cv. Starr (Spanish) was least susceptible, and cv. Florigiant (Virginia) was median. Peanut seed exposed to an excessive amount of organomercury for 36 hr sustained much greater damage from toxicity than did seed exposed for 12 hr. Increasing planting depth from 2 to 5 inches greatly increased the toxic response in seed from both exposure periods. Peanut seed treatment techniques should be refined according to commercial seed types to prevent both under and excessive applications of organomercury fungicides. The treating machine may require considerable improvement, and operators should be better trained.

SUPPORTED BY Georgia State Government

4.0291, WEED CONTROL IN PLANT INDUSTRY

N.C. GLAZE, Georgia Coastal Pl. Expt. Sta., *Tifton, Georgia* 31794 (GEO-02-0117)

OBJECTIVE: Develop adequate economical means of controlling weeds in crops grown for transplants which do not deleteriously affect the crops in question and that minimize the danger of herbicide residue accumulation. Initial work will be devoted to tomatoes because of the large industry volume.

APPROACH: Herbicides will be evaluated as their physicochemical and biological responses indicate. Various times of application will be investigated and also the influence of herbicide formulation.

PROGRESS: Herbicide evaluations were conducted on direct-seeded tomatoes and peppers. Pebulate has been found to be highly injurious when applied and incorporated shortly before tomato seeding. When applied 4 inches deep with covered sweeps, this injury has not been noticed. Combinations of two herbicides are also being evaluated in order to control a broader weed spectra and reduce the degree of crop injury obtained.

SUPPORTED BY Georgia State Government

4.0292, WEED CONTROL INVESTIGATIONS IN SEEDED AND TRANSPLANTED VEGETABLE CROPS

N.C. GLAZE, Georgia Coastal Pl. Expt. Sta., *Tifton, Georgia* 31794 (GEO-02-0120)

OBJECTIVE: Develop adequate, economical, and safe means of controlling weeds in vegetable crops which leave a minimum of herbicide residues in soils and on the harvested plant products. Work is in progress on sweetpotatoes, transplanted tomatoes, and some salad crops. New areas of investigation will lie within the cucurbit and legume groups.

APPROACH: Various herbicides will be evaluated according to their known selectivity and physico-chemical properties. Methods of application, timing, etc. will be considered to provide maximum protection with minimum quantities of herbicides.

PROGRESS: Herbicide evaluations were conducted on lima beans, cucumbers, watermelons, turnip and mustard greens. Nitrofen has given excellent weed control without injuring turnip or mustard greens. Nitralin was added as a recommended practice on cucumbers and watermelons. Other new compounds and combinations of herbicides were evaluated for weed control and crop tolerance on the previously named crops.

SUPPORTED BY Georgia State Government

4.0293, WEED CONTROL IN AGRONOMIC CROPS OF THE SOUTHEASTERN COASTAL PLAIN

E.W. HAUSER, Georgia Coastal Pl. Expt. Sta., *Tifton, Georgia* 31794 (0710-01-08)

OBJECTIVE: Develop economically suitable weed control practices and systems of weed control (including acceptable crop tolerance) for peanuts and crops grown in rotation, with emphasis on control of nutsedge. Determine the impact of changes in weed ecology in the Southeastern Coastal Plain. Determine persistence of herbicides in soil following various schemes of herbicide treatment. Develop improved techniques for application of herbicides. Also, determine losses caused by weeds.

APPROACH: Conduct intensive greenhouse and field experimentation envolving candidate herbicides, systems of herbicides, and herbicides plus mechanical weed control. Evaluate crop responses to weed control practices including yield and quality. Characterize persistence of herbicides in soil by use of bioassays.

PROGRESS: Continuing research with several systems of weed control in cotton, corn, peanuts, and soybeans grown continuously, and in several three-crop rotations, indicates that combining herbicides with cultivation is more efficient than using either herbicides or cultivation alone. In the absence of cultiva-

tion, more use of herbicides appears necessary for good weed control and this can lead to crop injury. Cultivation alone frequently failed to provide satisfactory weed control. -- Injection of butylate in soil at planting of corn combined with directed postemergence sprays of ametryne or linuron appears particularly effective for control of several troublesome species of weeds, including Panicum texanum, Digitaria spp., Cassia obtusifolia, Amaranthus spp., and Richardia scabra. -- A banded application of herbicides to half of the width of rows of cotton combined with cultivation controlled weeds as well as broadcast application of herbicides without cultivation, and in some instances as well as broadcast application with cultivation. Banding, as opposed to broadcasting, can be used to reduce the total amount of herbicide required, and it may prove more efficient when combined with cultivation.

SUPPORTED BY U.S. Dept. of Agriculture

4.0294, EVALUATION OF CHEMICAL COMPOUNDS AS NEMATOCIDES

A.W. JOHNSON, Georgia Coastal Pl. Expt. Sta., *Tifton, Georgia* 31794 (GEO-02-0125)

OBJECTIVE: Test chemical compounds for nematocidal activity, phytotoxicity, and specificity to various species of nematodes and develop soil fumigation on a practical crop production basis. Improve efficiency of soil fumigation through development of new application techniques. Feasibility of controlling wide range of crop pests through single pesticide applications.

APPROACH: Control of various nematode species will be measured by population change, root damage, and yield response of test crop following treatment with nematocides. Yield, plant vigor and color will be used to determine phytotoxicity. New equipment and modifications of existing equipment will be tested to determine methods of gaining maximum benefits from soil fumigation. The feasibility of controlling several crop pests with single application procedures will be studied by application of single, broad spectrum biocides or mixtures of specific biocides.

PROGRESS: Several new experimental nematocides show promise of controlling root-knot, sting, root-lesion, stubby-root and stunt nematodes on cotton, tobacco, sweet corn, lima bean, tomato, sweet potato and millet-sudangrass hybrids. Mixtures of specific pesticides applied in a single application, continue to show promise in controlling plant-parasitic nematodes, weeds and soil fungi in cotton and tomato transplants. Evaluation of pesticides and methods of application has made possible the achievement of 100 percent control of root-knot nematodes and good control of grasses and weeds in tomato transplants, which is necessary in transplant production. Complete control of root-knot nematodes on tomato transplants was also achieved this year by applying several nematocides separately through an over-head sprinkler irrigation system. This is the first account of nematicide application in this manner in transplant production.

SUPPORTED BY Georgia State Government

4.0295, CULTURE AND PHYSIOLOGY OF FLUE-CURED TOBACCO

J.D. MILES, U.S. Dept. of Agriculture, *Tifton, Georgia* (0500-04-02)

OBJECTIVE: Efficient cropping systems for flue-cured tobacco to improve yield and usability.

APPROACH: Examine interactions among cultural practices, such as varieties, sucker control methods, and leaf populations to improve production systems and methods. Aid production improvement program with biochemical and physiological studies of plant growth and development with emphasis on the function, mechanism and metabolism of growth regulators.

PROGRESS: A field experiment with flue-cured tobacco showed that 1-decanol (5%) was effective in controlling both terminal and axillary buds. Ethrel (2-chloroethylphosphonic acid) applied to these chemically topped plants at 150 mg ae per plant caused all leaves to yellow in four days. Leaves remaining on the stalk (65-70%) were harvested at once and cured in 3 days. Chemical composition of the cured leaf changed only slightly. A field experiment to study the interactions of N rates, sucker control chemicals and leaf ripeness at harvest showed that higher N increased yield but reduced price index. Sucker control chemicals increased yield and price. Tobacco harvested underripe had the highest filling value and lowest sugar content. The effectiveness of Ethrel in causing yellowing of flue-cured tobacco depends on whether the plants are topped or not-topped prior to treatment. Ethrel treatment did not produce a detrimental effect on the chemical quality of the leaf. Depending upon concentration, Ethrel either stimulates or retards tobacco seed germination and early seedling development. Further studies on the growth inhibiting substance present in young tobacco leaves indicate that it is an acyclic, weakly acidic substance. Preliminary GLC-mass spectrometry studies indicate a mass of 288 and infrared spectra show it to be a polyhydroxy compound with a ketone group present.

4.0296, ANTIMICROBIAL ACTION OF BIPHENYL AND DERIVATIVES ON CITRUS SPOILAGE ORGANISMS

F. SENSER, Ludwig Maximilians Universitat, *Munich, Germany* (HC-- (E10-AMS-3))

OBJECTIVE: Determine the mode-of-action of biphenyl and related compounds in order to obtain information useful for developing less toxic substitutes that would not affect the odor or flavor of the fruit.

APPROACH: Determine effect of biphenyl on germination and development of various citrus spoilage fungi. This will involve such studies as permeability of spores and mycelium to biphenyl and accumulation of the chemical in certain parts of the cells. Determine carbohydrate metabolism of the molds as influenced by biphenyl. Conduct studies on combination of biphenyl with other substances to reduce biphenyl concentrations needed. Study manner in which the organisms develop resistance.

PROGRESS: Biphenyl was found to be slightly inhibitory to hexokinase, glycerol-1-phosphate dehydrogenase, and Beta-hydroxyacyl- CoA-dehydrogenase. It is strongly inhibitory to phosphotransacetylase and glutamate dehydrogenase. Sodium orthophenylphenate (SOPP) has only a slight inhibitory effect on hexokinase and guanase. SOPP blocks phosphotransacetylase and glutamate dehydrogenase. The measurements indicating strong or blocking activities are assumed to be effective under the biological conditions of the use of the fungicides. Naturally occurring orange and lemon oils were found to inhibit the metabolism of Trichoderma lignorum. When small quantities of SOPP (10 mol/l) were combined with 0.4% lemon oil, respiration was completely blocked. The inhibiting of the oils increase strikingly with the addition of SOPP.

SUPPORTED BY U.S. Dept. of Agriculture

4.0297, PESTICIDE RESIDUE CLEARANCE PROGRAM

A. BEVENUE, Univ. of Hawaii, Agricultural Experiment Sta., *Honolulu, Hawaii* 96822 (HAW00613)

OBJECTIVE: Obtain pesticide residue data, spraying of crops with pesticides will be carried out. Samples will be taken and prepared in a form suitable for analysis.

APPROACH: Chemical analysis will be carried out. Analytical procedures for the determination of pesticides will be modified to make it applicable for the particular plant sample being tested.

PROGRESS: Residue studies on the miticide Morestan (6-methyl-2,3- quinoxaline dithiol cyclic carbonate) on papayas and papaya purees were completed, and the compiled residue and field data were submitted to Chemagro Corp., Kansas City, Mo., on March 14, 1968 to support petition to FDA for a residue tolerance. Residue studies on the same miticide are in progress on the macadamia nut. Thus far, no residue has been found in the edible portion. Residue studies on Diuron bracket3- (3,4-dichlorophenyl)-1, 1-dimethylurea closing bracket on papayas were completed; data sent to Dupont Co. to support registration petition. Residue studies are in progress on captan bracketN-(trichloromethylthio)-4-cyclohexene-1, 2-dicarboximide bracket on the taro root and on pentachlorophenol on the pineapple. Thus far, no captan residues are detectable in the taro root. Penthachlorophenol residues in the pineapple (fruit, bran, and crowns) range from 0.001 ppm in the fruit to 0.07 ppm in the bran. Supplementary research activities have produced useful related data described in the publications listed below.

4. PESTICIDES

SUPPORTED BY Hawaii State Government

4.0298, PESTICIDE RESIDUES IN PLANTS ANIMALS AND SOILS

J.W. HYLIN, Univ. of Hawaii, Agricultural Experiment Sta., *Honolulu, Hawaii* 96822 (HAW00609)

OBJECTIVE: Fate of pesticide residues on or in plants, animals, or soils; metabolism, growth and climatic variables may be investigated. Prevention, removal, or destruction of pesticide residues in or on treated plant parts, animals, or animal products development of new and/or improved methods for single and multiple pesticide residues.

APPROACH: Correlate residual levels of alkyl dithiocarbamate fungicides on plants with their phytotoxic effects. Identification of residual chemical responsible for these effects. Analyse for dithiocarbamate group and for metal ion to determine differential loss or metabolism of the sulfur and metal portions of the pesticide, rates of release of metals from the two types of compounds. Fungicide isotopically labelled with S or C . Fate of labelled compounds will be determined by isolation, identification, and quantitation of residual applied fungicide, metabolites and degradation products. Identified compounds will be studied for phytotoxicity.

PROGRESS: The total fate of dimethyldithiocarbamate fungicide residues on papaya has been determined. The principal products are conjugates of the fungicide residues with glucose and alanine. However, significant amounts are converted to volatile materials as carbon disulfide and carbon dioxide. In addition, a certain portion is metabolized to inorganic sulfate. There is no indication that hydrogen sulfide is formed. A perfusion apparatus has been developed to permit isolation of microorganisms from soil for the study of the microbial degradation of pesticide residues. Preliminary soil perfusion experiments indicate that the metabolic breakdown of DDT, diuron, dacthal and several other organochloride pesticides can be studied with this apparatus. Studies with certain soils indicate that the o,p'- isomer of DDT is preferentially degraded.

4.0299, PESTICIDE RESIDUE METABOLITES

J.W. HYLIN, Univ. of Hawaii, Agricultural Experiment Sta., *Honolulu, Hawaii* 96822 (HAW00611 F)

OBJECTIVE: Determine metabolic products formed when pesticides are applied to selected plants and soils. Biochemistry and toxicology of metabolites and their biological significance as residues.

APPROACH: The migration of the pesticide residue into and throughout the plant will be studied by radioisotopic and radioautographic techniques. Metabolites, if present, will be isolated from extracted plant material using procedures such as thin layer chromatography, column chromatography, electrophoresis, etc. Identity of isolated metabolite produced by various species will be estimated. Transformations of the pesticides by soil microorganisms will be studied. The toxicology of novel metabolites will be determined.

PROGRESS: The effects of organothiophosphate and organophosphate insecticides on purified enzymes other than acetylcholinesterose has been studied. Pepsin, trypsin, and chymotrypsin are not appreciably affected. Preliminary results indicate that alkaline phosphatase is 50% inhibited by 1-10 x 10 molar concentrations of a wide variety of phosphate insecticides. The metabolic fate of ring labelled diazinon has been studied on papaya plants. The principle metabolite is the pyrimidinol. This is further degraded into metabolites incorporated into the plants normal structure since radioactivity bound in proteins is found both above and below the point of application.

SUPPORTED BY U.S. Dept. of Agriculture

4.0300, THE RELATIONSHIP OF INSECTS TO THE LEAFROLL VIRUS DISEASE OF POTATO

G.W. BISHOP, Univ. of Idaho, Agricultural Experiment Sta., *Moscow, Idaho* 83843 (IDA00323)

OBJECTIVE: Conduct a survey to determine what insects inhabit potato fields and the relative abundance of those insects. Determine what insects are capable of transmitting the potato leafroll virus. Study the ecologies and life histories of the insects determined to be vectors. Determine the natural infectivity of the vectors and the vector-virus relationships.

APPROACH: Field observations will be made in the potato seed growing areas to determine what insects are capable of transmitting the leafroll virus. The life history, distribution, seasonal occurrence and overwintering habits of these insects will be determined. The effect of grower practices on vector and leafroll abundance will be studied. Vector-virus relationships will be studied by controlled inoculations of potato plants.

PROGRESS: Several systemic insecticides applied at planting time were evaluated for potato insect control in replicated field plots at Aberdeen, Idaho. Temik at three pounds actual toxicant per acre was significantly more effective than Temik at two pounds or disulfoton at three pounds. However, Temik at two pounds was more effective than disulfoton at three pounds. Liquid disulfoton had a shorter residual period and was initially less effective than the granular formulation. Several food sprays containing yeasts and sugars were applied to unreplicated potato plots for preliminary evaluation of the attractiveness of these materials to predators of the green peach aphid. No differences in predator numbers between treated and untreated areas was observed. One formulation was extremely phytotoxic. There was evidence that the applications should have been made about two weeks earlier. Laboratory colonies of the green peach aphid were established from collections made at various localities in Idaho. Preliminary results indicate that there are marked differences in the host preferences among the colonies. Counts to compare differences in insecticide susceptibility are in progress.

SUPPORTED BY Idaho State Government

4.0301, POTENTIAL EFFECTS OF HERBICIDES ON PLANT METABOLITES AND RESIDUES IN CROPS AND SOIL

L.C. ERICKSON, Univ. of Idaho, Agricultural Experiment Sta., *Moscow, Idaho* 83843 (IDA00546)

OBJECTIVE: Determine the accumulative effects of annual applications of certain herbicides on several crop and weed species and on the resulting herbicide residues in Palouse soil under prevailing environmental conditions; the infleunce of herbicide and environment on certain sugar protein or nitrogen fractions in several crops and on the status of herbicide residues in the crops at certain growth stages.

APPROACH: Five herbicides will be applied as weed control applications in the major crops. Three herbicide rates will be applied. Data will be obtained to determine their influence on: sugar and protein fractions in the crops, residues in both crops and soils, qualitative and quantitative weed populations, and continuing crop yields.

PROGRESS: 4 rates of picloram, igran, linuron, dicamba and silvex were applied pre plant in May. No herbicide affected the rapidity of emergence of peas, wheat, barley, flax or buckwheat. Linuron improved flax stands. Silvex, linuron, and igran increased pea yield. Picloram was not phytotoxic to buckwheat but delayed buckwheat maturity. It appeared that picloram caused protein depletion: linuron 14.7, silvex 14.5, igran 14.5, dicamba 14.0 and picloram 13.3. Protein in barley and wheat decreased as herbicide rates were reduced. These differences may be due to physiological effects from the herbicides. These differences could be the result of decreasing quantities of nitrogen available to the crop plants as weed populations increased. Variation in % sugar content were linuron 4.7, dicamba 4.5, picloram 4.3, igran 4.3 and silvex 3.9. Dicamba appears to be translocated into the seed of crops harvested from the dicamba treated plots, as seed germination rates were depressed and eventually diseases invaded. Delayed and reduced germination will reduce the seeds growth potential under field conditions. In September, surface soil samples (0-6') were taken from each plot, dried and stored until February. Peas were then used in bioassay to detect the presence of prevailing herbicides. All herbicides were detected and found to be residual. After 2 additional months, only picloram was detected in this bioassay.

SUPPORTED BY U.S. Dept. of Agriculture

4.0302, DEVELOPMENT OF SYSTEMIC PESTICIDES WITH LOW PHYTO- AND MAMMALIAN-TOXICITY PROPERTIES:
A.W. HELTON, Univ. of Idaho, Agricultural Experiment Sta., *Moscow, Idaho* 83843 (IDA00551)

OBJECTIVE: Evaluate new structures in vitro against a Cytospora fungus, and other organisms as appropriate. Evaluate candidate compounds for host toxicology-compatibility via root-absorption, stem absorption, and foliar absorption. Evaluate candidate compounds for pest-control efficiency in the laboratory, in a greenhouse, and in field plots. Study metabolism of tested structures in host plants.

APPROACH: In vitro assays will evaluate compounds for contact- toxicity to assay fungus and provide reference curves for estimation of concentration detected in treated host tissues by bioassay. Host toxicology studies will provide information on the upper limits at which candidate compounds can be used and the rate of translocation in host tissues. Pest control studies will be conducted with Cytospora and Coryneum canker fungi, with mildews, and with other pests as appropriate so that effective structure can be located.

PROGRESS: Sixteen compounds were investigated repeatedly in laboratory assay against a Cytospora fungus. Most promising of these were Aureofungin, TBZ, and G-20072, where growth of the fungus was inhibited completely as concentrations as low as 1.5 ppm in the culture medium. Other materials were promising also, i.e. at 1.5 ppm RH-893 inhibited growth 80%; Streptimidone, 70%; Busan 72, 60%; TCMTOB, 55%; Antimycin-A, 53%. None of these materials could be tested in plot trees because of the extreme damage done by the 1968-69 winter period, and consequently no report can be presented which deals with performance in vivo. Laboratory and greenhouse investigations into the physiology of Cytospora canker development in peach trees are not sufficiently complete for reporting at this time.

SUPPORTED BY U.S. Dept. of Agriculture

4.0303, ILLINOIS CONSUMERS' REACTION TO USE OF PEST CONTROL ON AGRICULTURAL PRODUCTS
M. DUNSING, Univ. of Illinois, Agricultural Experiment Sta., *Urbana, Illinois* 61801 (ILLU-60-0365)

OBJECTIVE: Obtain insight concerning the Illinois consumers' knowledge, attitudes, acceptance and demand for agricultural products subjected to varying degrees and alternative methods of pest control.

APPROACH: Phase 1--The following tests and scales will be developed concerning the use of pesticides on agricultural products: consumer knowledge test; attitude scale to determine attitudes and intensity; consumer acceptance test; consumer demand test. A pilot study of households in the Champaign-Urbana area will be undertaken to test these measures. Phase 2--The above measures will be test these measures. Phase 2--The above measures will be used with a representative sample of households in Illinois. Phase 3--A study will be made of consumer acceptance of agricultural products known to be pesticide treated or non-treated.

PROGRESS: For the 704 usable records, the significance of the relationships (chi-square) between the 26 independent variables and the knowledge and attitude statements was determined as was the significance of the relationships between the knowledge and the attitude statements. A linear regression model was used to test the following: the respondent's attitudes concerning the use of pesticides in food production are an explicit function of the occupation, education, and family income of husbands and wives, their knowledge about pesticides, the extent of use of pest control chemicals around the house and yard, the extent to which they think substances should be added to food to decrease spoilage, the extent to which they would buy fruits and vegetables if labelled 'pest control chemicals used in growing' as well as whether they would be willing to pay more for fruits and vegetables to eliminate the use of pest control chemicals and how much more. On the other hand, the respondent's attitudes are not an explicit function of the other factors obtained such as number in the family, owning or renting, health problems, etc. The findings to date indicate that a need exists for educational programs in this area. The type of information needed in these educational programs will be indicated as a result of this project. Papers are currently being written and will be submitted for publication.

SUPPORTED BY U.S. Dept. of Agriculture

4.0304, PHYSIOLOGY AND CONTROL OF WEEDS IN SOYBEANS
L.M. WAX, Univ. of Illinois, U.S.D.A. Crops Research Div., *Urbana, Illinois* 61801 (0710-01-09)

OBJECTIVE: Develop new and improved means of weed control in soybeans and investigate differential aspects of the physiology, biochemistry, and ecology of crops and weed.

APPROACH: Conduct research program including evaluation of new herbicides and methods of application. Determine the extent and nature of losses resulting from weed infestations. Conduct life cycle studies on specific problem weeds. Correlate physiological differences in weeds and soybeans with selectivity of herbicides.

PROGRESS: Greater proportions of amiben absorbed through roots appear to be translocated to shoots in susceptible plants than in tolerant plants. Tolerant species appear to fix more of the absorbed amiben in roots as nontransportable N-glucosyl amiben, and we believe that this action can account for most of the differences between tolerant and susceptible species in the amounts translocated to the shoots. -- Soybean-weed competition studies indicated that 4 to 5 weeks of weed control is required after planting until soybeans can compete effectively with common annual weeds in the row. Thereafter, weeds emerge but are unable to compete with soybeans, presumably because of the heavy shading by the soybeans. -- Buried seed of several species of weeds germinated almost equally well from 1/2 to 2-inch depths, but few emerged from 4 inches. Ambrosia trifida, however, emerged readily from seed at depths of 1/2 to 4 inches. Ambrosia artemisiifolia, A. trifida, and Polygonum pensylvanicum emerged early in the season, but very little thereafter. Abutilon theophrasti emerged early and continued for some time thereafter in the season. Ipomoea spp., Datura stramonium, and Setaria glauca emerged throughout the season. -- In studies on harvesting soybeans, 40,000 pigweed plants/A reduced soybean yields about 25% by competing, and caused an additional loss by increasing harvesting losses. The increased harvesting losses were mainly in threshing rather than in gathering.

SUPPORTED BY U.S. Dept. of Agriculture

4.0305, STORED GRAIN INSECT PESTS AND THEIR CONTROL IN UTTAR PRADESH, INDIA
B.P. KHARE, Uttar Pradesh Agric. Univ., *Nainital, Uttar Pradesh, India* (SP68(A7-MO-15(K)))

OBJECTIVE: Determine losses caused to grains by insects and develop insecticide control measures including effect of residues on the grains.

APPROACH: First, kind and amount of damage and kinds of insects will be determined from samples taken in 5 climatic zones of Uttar Pradesh. Second, the effect of moisture, heating and C0(2) on biology of the insects will be studied. Old methods of storage to be studied as base to develop new methods that will reduce losses specially in farmers' homes. Third, insecticides will be evaluated for biological effectiveness and for potential adverse effects of their residues on grains in laboratory tests and under actual storage conditions.

PROGRESS: A survey of different zones of Uttar Pradesh was conducted as earlier reported. Samples of wheat, maize, and paddy were analyzed for quantitative and qualitative losses. The past year's work was devoted to assessing: (1) weight loss of grain, (2) loss of germination, (3) estimation of avoidable losses by EDB fumigation, (4) effect of insect feeding on protein content, (5) effect of type of storage structure and zones on nonreducing sugars of grain and free fatty acid values. A study of insect population in different zones in relation to type of structure being used by the farmers for storage of different grains was also conducted. The loss in weight found due to insect feeding in paddy and maize

varied from 0.16 to 5.87 percent and 0.91 to 10.86 percent, respectively. A decrease in the protein content was evident in the germ and endosperm-eaten kernels of maize, but there was an increase in the protein of infested paddy kernels.

SUPPORTED BY U.S. Dept. of Agriculture

4.0306, INTERACTION EFFECTS OF HERBICIDE COMBINATIONS ON GROWTH AND RESIDUES IN PLANTS

L.L. DANIELSON, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (0710-03-10(CA))

OBJECTIVE: Determine phytotoxicity and interaction effects on crop plants, including residue levels, of herbicide mixtures and combinations.

APPROACH: A systematic study will be undertaken to determine the interaction effects of specific herbicides chosen on the basis of present knowledge of the mode of action of each individual material. An attempt will then be made to determine if other herbicides having a similar mode of action will give the same kind of interaction. For example, dinitrophenols are highly synergistic in combination with the photosynthetic inhibitor, simetone. Initially, the research will be conducted in the greenhouse, growth rooms, and laboratories, but the results will be checked out under field conditions. Penetration, translocation, degradation, and residues of herbicides and combinations in plants will be studied.

PROGRESS: In studies to determine plant structural parts receptive to herbicides preparatory to investigations of the effects of herbicide combinations, EPTC, chlorpropham, propham, and CDEC did not affect pea shoot growth but the shoot zone adjacent to the crown root node of corn was highly sensitive. Growth of corn was reduced and crown roots severely inhibited. Shoots of corn and peas were sensitive to diuron. In corn the shoot adjacent to the crown root node and the tissue of the first internode were the most susceptible. The uppermost shoots of peas below the soil surface were most sensitive. Trifluralin did not affect growth of corn and peas when placed in the shoot zone after emergence although the crown roots of corn were severely inhibited. Naptalam, dalapon, and 2,4-D did not affect growth of corn under similar conditions and of these herbicides, only 2,4-D reduced growth of peas. Wheat, barley, and oat plants were severely injured when treated with EPTC at the coleoptilar internode. Sorghum plants were severely injured regardless of the shoot zone exposed. Thus sorghum is considered most susceptible to EPTC, and wheat, barley, and oats equally tolerant of this herbicide. The results suggest that growth responses to EPTC are dependent on the stage of plant development at time of treatment. In studies of herbicide combinations, an antagonistic response of EPTC and 2,4-D was observed when the herbicides were applied to sorghum plants.

SUPPORTED BY U.S. Dept. of Agriculture

4.0307, INSECT PESTS OF CUCURBIT CROPS

G.E. GOULD, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (INDO1059)

OBJECTIVE: Not Provided.

APPROACH: Not Provided.

PROGRESS: The principal insect pest of cucurbits, the striped cucumber beetle (Diabrotica vittata (F.), was controlled by applications of dieldrin repeated 5 to 7 times up to blossoming. Several carbamate insecticides were found to be effective. The two best were carbaryl and Furadan (reg.trademark). Carbaryl caused some phytotoxicity to cucumbers resulting in stunting and delayed maturity, especially under high relative humidity and temperature. Plots treated with Furadan(reg.trademark) were superior to all others and had little or no beetle feeding and bacterial wilt. These plots had larger plants and higher yields. Best control with all materials was obtained by repeating applications at 3 to 7 days, depending upon rainfall and plant growth. Bacterial wilt, which is carried only by the cucumber beetles, could be controlled only by the presence of a good insecticide on the foliage when beetles migrated into the plots. Granular materials applied around the base of the plants or preplanted in the soil did not give protection against beetle attack. Carbaryl is now the recommendation against beetles on cucurbits in Indiana, while Furadan(reg.trademark) could be added if FDA clears a tolerance for these crops.

SUPPORTED BY Indiana State Government

4.0308, TRACE LEVELS OF PESTICIDE RESIDUES IN AGRICULTURAL COMMODITIES IN MARKETING CHANNELS

F. CARLIN, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010 (IOW01624)

OBJECTIVE: Study the effects of pesticides on acceptability and/or nutritive value of agricultural commodities. Develop procedures for the removal, reduction or de-toxification of pesticide residues and conversion products in agricultural commodities. Develop or improve methods for determining pesticide residues in agricultural commodities in marketing channels.

APPROACH: Determine effects of 2, 4-D on acceptability of grapes, tomatoes, strawberries, and snap beans. The influence of preparation and processing techniques on stability of pesticides in fruits and vegetables. The effects of X-ray and beta radiation, freezing, storage, dehydration and possible chemical antagonists on malathion in eggs and broiler tissue. Develop new chemical or non chemical detection methods.

PROGRESS: Pigment extraction and column chromatographic procedures indicated that beta-carotene, lycopene or total pigments in tomato juice were not affected by sublethal doses of 2,4-D on tomato plants grown in greenhouses. Juice made from treated and control Heinz tomatoes were similar in color measured by a Hunter Color Difference Meter and flavor evaluated by a trained taste panel. Further studies of malathion application to the chicken indicated that in vivo degradation was more complete than previously demonstrated in in vitro conditions with partially purified liver carboxyesterase. Only trace amounts of ingested pesticide remained intact in the feces. The addition of volite 2,4-D in a concentration of 1 ppb to the atmosphere surrounding grape and tomato plants adversely affected the fresh market quality of the fruit harvested from these plants under certain environmental conditions. Thus, it would seem that no direct relationship between the level of 2,4-D in the atmosphere and the degree of adverse effect on fruit quality can be determined without regard to the specific environmental conditions previous to and during exposure. Evidently malathion degradation in the hen's body is controlled at least in part by the carboxyesterase enzyme system. Mono-acid and di-acid forms of malathion are the major metabolites even though other forms were isolated.

SUPPORTED BY U.S. Dept. of Agriculture

4.0309, HERBICIDES - THEIR ADAPTATION TO HORTICULTURE CROPS, AND STUDIES OF CONTAMINATION

E.L. DENISEN, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010 (IOW01519)

OBJECTIVE: Determine herbicide adaptation for the specific horticultural crop areas: vegetables, turf, ornamentals and fruits; and develop herbicide and cultivation programs on a seasonal plan based on edaphic, ecological, and physiological factors. Consider economic factors in terms of labor requirement, herbicidal efficiency, and crop performance. Expose horticultural plants to minimum contaminating concentrations of chemicals of the 2,4D type as could occur from vicinity sprays or 'leaky' storage and obtain representative data on effects of these herbicides on performance of selected plant materials in regard to production, ornamental value, and ability fo propagate sexually and asexually.

APPROACH: In adptations of herbicides for vegetables, turf, ornamentals, and fruits, herbicide programs will be developed on a seasonal basis considering the ecological factors of soils, rainfall and temperature and the physiological factors of species and variety response, cuticular condition, carbohydrate levels and differentiation. Economic factors of cost and yield influence will be studied. In herbicide contamination studies a minimum concentration of 2,4D needed to produce visual symptoms will be established. A main trial of concentric rows of several species with a source of contaminant in the center will provide information on physiological, morphological and yield effects.

PROGRESS: At sustained sublethal 2,4-D exposures (1 ppb), zinnia seed misshapen and poor vitality. Premature germination of ripening seeds in the seed heads was not found in 1969. Pin oak and sugar maple trees were markedly stunted, ceased yearly growth sooner and exhibited premature senescence symptoms including tattered and lost foliage, but did not show appreciable growth deformations. Cabbage did not show typical malformation but split and stunted heads were clearly associated with the higher exposures. Maturity of tomato, pepper and bean exposed from before set was markedly delayed. Although photographical documentation was stressed, color infrared (closeup or airplane view) did not aid interpretation of results.

SUPPORTED BY U.S. Dept. of Agriculture

4.0310, FUNGICIDAL & FUNGISTATIC PROPERTIES OF ANTI-OXIDANTS AND RELATED COMPOUNDS

A.H. EPSTEIN, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010 (IOW01723)

OBJECTIVE: Determine fungistatic and fungicidal activity of selected compounds supplied by U.O.P. and test active compounds for possible protective and/or systemic activity in plant disease control. Volatile compounds of low mamalian toxicity will be tested for efficacy in controlling storage molds.

APPROACH: Compounds of low mamalian toxicity with suspected fungistatic or fungicidal activity will be bioassayed in an inhibition plate type of test against Ceratocystis ulmi (Dutch elm disease) and Botrytis sp. (Nursery storage mold). Systemic activity of active compounds will be determined by application on elm seedlings growing in the greenhouse. BA and BHA, both volatile, low toxicity compounds, will be tested for efficacy in controlling mold development on high moisture corn in small-scale storage. Results will be used in considering establishment of field scale tests.

PROGRESS: The following compounds supplied by the Universal Oil Corporation are being tested: (1) Benzo furoxane (2) B.H.Q. (Butylated Hydro Quinone). Tests to date indicate that both compounds are active against Ceratocystis ulmi giving good inhibition zones in agar previously seeded with spores of the fungus. Both compounds are moderately soluble in water. Further tests to determine phytotoxicity, methods of application and activity against other plant pathogenic fungi will be investigated. It is expected that this phase of the project will be continued. B.H.Q. has Food & Drug Administration clearance as a food additive and in this project was tested for possible use as a control for storage molds in high moisture corn. Although preliminary tests indicated that surface mold development was delayed in large scale tests using CO(2) evolution as a measure of fungal activity total degradation of treated corn was not significantly different from the untreated control. This phase of the project will not be pursued further.

SUPPORTED BY Iowa State Government - Des Moines

4.0311, MONITORING AND ASSAY OF PHYTOTOXIC AIRBORNE PESTICIDES AND VOLATILE POLLUTANTS

C.H. SHERWOOD, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010 (IOW01802)

OBJECTIVE: Evaluating (uncontrolled) air pollution cases involving appreciable concern to the public or damage to crops. Detecting pollution incidence in representative Iowa rural and urban areas and improving use of instruments and biological tests. Relate damage potential to plant characteristics, pollutants, pollution patterns and environment. Provide concerned gardeners and commercial growers means for limiting damage from air pollution.

APPROACH: Obtain notification of pollution and other cooperation by extension personnel and state horticultural organizations. Monitor and assay representative rural and urban sites for pollution as related to environmental conditions, identifying advantages and disadvantages of instrumentation and biological tests and relating to sources and risks. Through controlled exposure patterns and pre- and post-exposure conditions improve diagnosis and prognosis procedures relating to 2,4-D, NH(3), O(3), SO(2) and other pollutants, pollutant combinations and patterns. Test use of indicator plants and observation training for concerned gardeners. Test advantages of incorporating warning or marking agents in high risk home-use packaged pesticides and formulations of profesional applicators. Develop use of protective or antagonistic materials such as organic irons, sequestrins and oxidation catalysts against known or expected pollutants.

PROGRESS: New treatment facilities and bottled gas injections produced more predictable effects (O(3), NO(2), SO(2), HCl, Fl, NH(3), H(2)S, 2,4-D singly and in combinations). Bluegrass, oat, tomato, bean and zinnia and 10 and 20 minute exposure sets typically used. Additive effects less than 1 1, no synergism, only O(3) and 2,4-D markedly less (10 X) together. However, morphactin and ethrel plus 2,4-D markedly increased effect and may be a synergism. Air sampling was conducted at two locations near Ames. One station had samplers at 1 m and 15.2 m above ground, the other only at 1 m. The number of days with pollutants was about the same as 1968, but with lower concentrations. More pollutants were found at the farm station than the urban station at the 15.2 m height. Most common compounds detected were 2,4-D and DDE. In rain samples the most common compounds were dieldrin, kelthane and endrin.

SUPPORTED BY U.S. Dept. of Agriculture

4.0312, FATE AND SIGNIFICANCE OF LABELLED PESTICIDES RESIDUES IN RICE

C. TOMIZAWA, Natl. Inst. of Agric. Sciences, *Tokyo, Japan*

Rice is a staple food crop consumed by the greater part of Asian people, and the majority of Asian countries executed various programes for the increase in rice production in order to prevent the starvation of the people caused by rapid increase of population. In this connection, although the important and growing role of chemicals for protecting rice is confirmed, public sensitivity to the problems of food and environmental contamination of all kinds has increased recently. It is essential that the evaluation of toxicity of pesticide residues be made with total residues including not only pesticide itself but also its decomposition products which might be toxic to mammals. Such comprehensive survey of pesticide residues is sometimes difficult to perform by means of a single analytical equipment. For this purpose, isotope tracer techniques may provide a powerful and unique tool. As a programme of first year of work, organo-phosphorus compounds, fungicides for rice blast disease, is taken up, and fate and nature of C14, P32 and (or) S35-labelled compounds in rice are examined.

SUPPORTED BY Intl. Atomic Energy Agency - Austria

4.0313, SUGAR BEET VARIETAL AND HERBICIDE INVESTIGATIONS

E.E. BANBURY, Colby Branch Agric. Expt. Sta., *Colby, Kansas* 67701 (KAN-05-892)

OBJECTIVE: Evaluate comparative yield performance, sucrose percentage and disease tolerance of sugar beet varieties, evaluate sugar beet selectivity and weed control performance of selected herbicides, determine yield, sucrose percentage and chemical residue in sugar beets treated with herbicides, evaluate time and amount of herbicide applications to sugar beets.

APPROACH: The sugar beet variety trial will be composed of 8 hybrids and one open-pollinated variety for comparison. These to include types for resistance to leaf spot and/or curly top disease. In the herbicide trials, weed seed will be sown prior to or during experiment establishment to insure the presence and more uniform dispersion of weeds. Herbicide applications are to be made pre-plant and pre-emerge at variable rates. Weed and beet seedling counts will be taken in evaluation of weed control and crop injury. In addition, visual estimates of weed control effectiveness and crop retardation will be included.

PROGRESS: Objectives. (1) To evaluate comparative yield performance, sucrose percentage and disease tolerance of sugar beet varieties, (2) to evaluate sugar beet selectivity and weed control performance of selected herbicides, (3) to determine yield, sucrose percentage and chemical residue in sugar beets treated with herbicides, (4) to evaluate time and amount of herbicide applications to sugar beets, (5) to study the economics of cultural practices in the production of sugar beets following grain sorghum. Progress: A variety test near Goodland in 1968 included

12 varieties. Test results are not yet available. Five herbicide tests were conducted with a total of 85 treatments. Included were variable such as herbicides or experimental chemicals, combinations of herbicides, rate, and time of application (preplant and preemerge). Notes on differences in degree of weed control, selectivity of the chemicals, optimum rate of application, and amount of crop retardation were obtained. Preliminary work involving cultural practices in the production of sugar beets following grain sorghum was started in 1968. Beets will be planted in the spring of 1969 to complete the sequence.

SUPPORTED BY Kansas State Government - Topeka

4.0314, WEED CONTROL INVESTIGATIONS
W.M. PHILLIPS, Fort Hays Br. Agri. Expt. Sta., *Hays, Kansas* 67601 (KAN00304)

OBJECTIVE: Research objectives are to discover more efficient chemical, cultural, mechanical, biological, nd combination methods of controlling annual and perennial weeds in sorghum, winter wheat, summer fallow, and other crops grown in rotation.

APPROACH: The following research is proposed: Application of pre- emergence and post-emergence herbicides on sorghum to determine their effect on the crop and their capabilities for weed control in the crop. Study differential varietal responses of sorghum and winter wheat to herbicides. Determine the penetration, movement, and persistence of herbicides in soil, and study the effects of herbicidal treatments on subsequent crops. Examine the effectiveness of herbicides in combination with minimum tillage practices for controlling weeds throughout summer fallow-wheat-sorghum and summer fallow-wheat rotations, and study the effect of these treatments on conservation of moisture. Determine the role of surfactants, repeat treatments, and other techniques in reducing the total amount of herbicide needed to control weeds.

PROGRESS: Work continued on the herbicide-minimum tillage concept of weed control in a wheat-sorghum-summer fallow rotation. In 1969, plots which received an application of atrazine after the 1968 wheat harvest and were tilled twice prior to seeding sorghum became infested with weedy grass. In spite of this competition, these miminum tillage plots yielded substantially more grain than the plots which were tilled conventionally. The concept of herbicide-zero tillage for fallow prior to sorghum production has been largely abandoned, except for academic interest, at least until more satisfactory herbicides are developed. New herbicides and combinations of herbicides applied pre...rgence showed considerable promise for controlling weeds in sorghum without causing undue crop injury. Combinations which involved an effective broadleaf weed herbicide and an effective grassy weed herbicide gave impressive broad spectrum weed control. Observations were continued on plots previously treated for field bindweed (Convolvulus arvensis L.) control. Picloram and 2,3,6-TBA are effective bindweed control herbicides, but both chemicals persist in the soil for extended periods.

SUPPORTED BY Kansas State Government - Topeka

4.0315, RELATION OF CHEMICALS AND CULTURE TO RESPONSE OF FRUIT PLANTS
R.W. CAMPBELL, Kansas State University, Agricultural Experiment Sta., *Manhattan, Kansas* 66502 (KAN00265)

OBJECTIVE: Determine the influence of various chemical compounds used as insecticides fungicides, herbicides, growth regulators, or fertilizers on the photosynthetic activity, blossom bud formation, fruit production or vegetative characteristics of fruit plants.

APPROACH: These studies are designed to measure detailed responses of some horticultural corps to chemical pesticides, fertilizers and growth regulators. The effects of chemicals on plants under varying environmental conditions have been studied. Work has been conducted in the field, greenhouse and laboratory. Laboratory techniques employed in plant tissue analyses include colorimetry, spectrophotometry and chromatography. Growth tests involving bio-assay plants have been utilized. The use of radioactive tracers is planned for future work.

PROGRESS: Jonathan apple trees were randomly sprayed with aqueous solutions of TIBA and B-9 in May 1968. No significant differences between treatments and controls was noted in terms of terminal growth, twig diameter, and number of flowers in April 1969. A study to determine the effect of succinic acid, 2,2-dimethylhydrazide (Alar) on zinc translocation in 2 year old greenhouse grown pecan trees was carried out. Two months after planting a foliar applications of Alar were made followed by a soil treatment of Zn 65. Results showed the uptake of Zn 75 was too low to produce significant results. A tissue analysis with atomic absorption of tomato plants sprayed with Zn sulphate and Alar failed to show a positive correlation between Alar and Zinc translocation. A study was initiated to determine the changes in nitrogenous compounds, enzyme activity and other physiological phenomena in two garden pea varieties under conditions of water stress as influenced by B-9. Seed of Alaska (drought susceptible) and Burgess (drought resistant) varieties were germinated in vermiculite and transplanted to a culture solution. After establishment B-9 was added to the solution as were different concentrations of carbowax to produce low, medium and high water stress conditions. Plants were harvested one week after carbowax treatment and assays for protein, nitrate, amino acid, nitrate reductase, and glutamine synthetase were conducted immediately after harvest. Relative turgidity, transpiration rate and dry weight of plants also was determined.

SUPPORTED BY U.S. Dept. of Agriculture

4.0316, WEED CONTROL IN HORTICULTURAL CROPS
J.K. GREIG, Kansas State University, Agricultural Experiment Sta., *Manhattan, Kansas* 66502 (KAN00621)

OBJECTIVE: Study mode of action of herbicides on weed species at various stages of development. Determine effects of chemical herbicides on horticultural plants. Develop effective methods of controlling weed species in horticultural crops.

APPROACH: Study effect of time and rate of application of chemical herbicides to problem weed species in horticultural plantings. Obtain basic information concerning effects of chemical herbicides on growth and development and quality of horticultural plants. Evaluate various methods of weed control in horticultural crops.

PROGRESS: Post-emergent applications of RP2929 (4-dimethylamino- thiocyanobenzene) and RP17623

SUPPORTED BY U.S. Dept. of Agriculture

4.0317, INVESTIGATIONS OF CEREAL AND FORAGE CROP DISEASES AND THEIR CONTROL
E.D. HANSING, Kansas State University, Agricultural Experiment Sta., *Manhattan, Kansas* 66502 (KAN00076)

OBJECTIVE: Investigate the causal organism, physiological race, disease, environmental factors affecting the organism and disease, and control through cultural practice, disease resistance, and fungicides (including the effect of the fungicide on the plant) on wheat, oats, barley, sorghum, and other cereal and forage crops.

APPROACH: Physiological races of fungi which occur naturally in Kansas will be used: Tilletia foetida, Ustilago tritici, U. avenae, U. kolleri, U. nuda, U. hordei, U. nigra, Sphacelotheca sorghi, Erysiphe graminis tritici, Puccinia graminis tritici, and P. rubigovera tritici (the last 2, control with fungicides only). Standard and experimental fungicides will be used. Experiments will be conducted in the field, greenhouse, and laboratory.

PROGRESS: Experiments were continued (cooperation with plant breeding) to develop wheat cultivars resistant to bunt and loose smut, barley resistant to brown loose smut, and oats resistant to loose smut and covered smut. Extensive experiments were conducted to determine the effect of the systemic fungicides Benlate (benomyl) and Plantvax (oxycarboxin) on control of rusts of wheat. Single applications of Benlate and Plantvax partially controlled leaf rust and increased yields, test weights, and 1000 kernel weights of the cultivars Bison, Parker, and Shawnee. They also partially controlled both leaf rust and stem rust in the cultivar Yorkstar (white winter wheat) and increased its yield, test weight, and 1000 kernel weight. Vitavax effectively controlled loose smut of wheat and brown loose smut of barley. Twenty- one farmers' samples of 4 loose-smut susceptible cultivars of Kansas wheat (non-treated, 0.2 - 14.5% infected spikes)

were treated with Vitavax at 4 oz/cwt of seed. Complete control of loose smut was obtained in treated seed of 19 samples while 0.1 and 0.2% occurred in 2 samples. Experiments are being conducted to determine the effect of the fungicide Plantvax (oxycarboxin) on the metabolism of wheat plants grown in nutrient solutions.

4.0318, FATE OF MALATHION RESIDUES ON GRAIN SORGHUMS

A.H. KADOUM, Kansas State University, Agricultural Experiment Sta., *Manhattan, Kansas* 66502 (SP34(A9706))

OBJECTIVE: Determine degradation and metabolism of malathion on stored living and autoclaved grain sorghum.

APPROACH: Sorghum varieties having different seed coat textures will be used in metabolic study of malathion. Identity of malathion and metabolic products to be made by paper, thin layer and gas liquid chromatography. Radioisotope tracer techniques will detect metabolites. Degradation and metabolism of malathion residues on living and autoclaved sorghum and on glass to be studied. Drosophila melanogaster to be used in toxicity evaluation of degradation products.

PROGRESS: Separation and determination of malathion and some of its metabolites from stored grains by thin-layer chromatography has been completed. Studies on the effects of some organophosphorous compounds and their metabolites on sorghum grain, esterase, and certain insects attacking sorghum grain have been accomplished. Comparison studies on the fate of malathion in corn, wheat, and sorghum are currently in progress. The effect of different sources of light on malathion and its metabolic products are being investigated.

SUPPORTED BY U.S. Dept. of Agriculture

4.0319, FATE OF MALATHION RESIDUES GRAIN SORGHUMS

A.M. KADOUM, Kansas State University, Agricultural Experiment Sta., *Manhattan, Kansas* 66502 (KAN-05-912)

OBJECTIVE: Determine initial and aged malathion residue levels to study disappearance rates and behavior patterns; Study malathion metabolism on sorghums and determine the metabolic products.

APPROACH: Compare degradation of malathion residues on living and autoclaved sorghums and determine effects of temperature, light, and humidity on malathion degradation; and compare malathion metabolism on live sorghums, autoclaved sorghums, and glass surfaces and investigate the enzymes that are active in malathion degradation.

PROGRESS: Extraction and cleanup methods were studied to determine malathion and its hydrolytic products using gas-liquid chromatography. Use of acidified acetone extraction is satisfactory for routinely analyzing samples containing malathion, malathion half-ester, and malathion dicarboxylic acid in the presence of waxes and pigments of the grain sorghum, corn, and wheat. The acids are quantitatively converted to their methyl esters by reaction with BF(3)-methanol. Malathion was applied to grain sorghum from 6 hybrids at one pint of 57% emulsifiable concentrate per 1000 bushels. Little hybrid effect on malathion degradation was found during 12 months' storage at 80 F and 60% relative humidity. Grain moisture content and storage temperature significantly affected residue retention but foreign material had no effect on the rate of malathion disappearance.

4.0320, ATOMIC AND NUCLEAR RESEARCH WITH ACCELERATORS

R.B. LEACHMAN, Kansas State University, School of Arts, *Manhattan, Kansas* 66502 (AT(11-1)-1766)

In nuclear physics, emphasis will be on heavy-ion scattering, many- nucleon transfer in heavy-ion reactions, properties of highly deformed nuclei as studies by fission isomers, nuclear lifetime measurements by the Doppler shift attenuation method, and coulomb excitation with heavy ions. In addition, research of current interest with proton-induced reactions will be undertaken by studies of analog states and proton- induced gamma rays. In atomic physics, measurements will be made of charge-changing cross sections for slow heavy ions, production of ions with negative charge for tandem Van de Graaff ion sources, and ionic charge changing processes for fast heavy ions. Stopping of heavy ions in solids will concentrate on channeling properties in thin, single crystals. The use of heavy-ion scattering from food-stuffs will continue in development as a method of detecting trace amounts of pesticides.

Results: Detailed comparison has been made of the prompt and isomer fission of Am242. Lifetimes of excited states of K39 have been measured by the Doppler shift method. Charge changing cross sections for fluorine ions have been measured. Trace amounts of pesticides in foodstuff have been observed by oxygen ion scattering.

SUPPORTED BY U.S. Atomic Energy Commission

4.0321, CYTOGENETIC EFFECTS OF ATRAZINE ON GRAIN SORGHUM

G.H. LIANG, Kansas State University, Agricultural Experiment Sta., *Manhattan, Kansas* 66502 (KAN-05-897)

OBJECTIVE: Plant abnormalities induced by herbicides have often been reported. These abnormalities sometimes are transmittable from generation to generation. Transmittable changes in plants induced by herbicides may be caused by a genetic alteration. A better understanding of the cytogenetic response of plants of herbicides, and of their changes in chemical composition would provide useful information not only to effective and safe weed control but also to the comprehension of basic genetic mechanism. Determine changes in chemical composition and cytogenetics following application of atrazine.

APPROACH: My previous work has demonstrated that abnormal chromosome behavior in sorghum plants occurred as a result of atrazine application. The mechanism of inducing such irregularities should be further explored. Abnormal chromosomal behavior may be related to the alteration of certain metabolic pathways and to the misfunction of genes.

PROGRESS: Grain sorghum (Sorghum bicolor (L.) Moench) was sprayed with 2-chloro-4-ethylamino-s-triazine (atrazine), propylene glycol butyl ether ester of 2,4-dichlorophenoxyacetic acid (2,4-D), alkanolamine salts of 2,4-D, and nonphytotoxic petroleum oil (crop oil) or their combinations when plant heights were 2 to 4, 4 to 6, and 6 to 8 inches for grass weeds, broadleaf weeds, and sorghum, respectively. Microscopic examinations of pollen mother cells from all herbicide- treated sorghum revealed chromosomal aberrations, mostly aneuploidy and polyploidy, and aberration frequencies increased when herbicides were combined. Increases in chromosome numbers were observed in various meiotic stages. The mechanisms for increasing chromosome number probably differs from that of colchicine. The cells containing multiples of a nonbasic number of chromosomes, fragments and bridges, and micronuclei could cease to function or be less competitive than normal pollen since morphological abnormalities or differences in seed setting and germination percentages were not found from plants derived from previously atrazine-treated plants.

SUPPORTED BY Kansas State Government - Topeka

4.0322, INVESTIGATIONS WITH ORNAMENTAL PLANTS

C.E. LONG, Kansas State University, Agricultural Experiment Sta., *Manhattan, Kansas* 66502 (KAN00213)

OBJECTIVE: Investigate the adaptability of woody ornamental plants to Kansas. Also to supply information on propagation material from proven adaptable plants to nurseries and the trade for further trial. It is proposed that the 35 years of growth records on ornamental trees and the 20 years of records on ornamental shrubs can be published in bulletin form.

APPROACH: This project is divided into three phases: Growth records of campus trees. Growth records of deciduous and broadleaf evergreens in the shrub collections. Plant propagation studies.

4. PESTICIDES

PROGRESS: Repeat applications of Dichlobenil at rates up to 200 ai/acre for three years have resulted in no observable phytotoxicity to selected ornamentals. Rooting studies of ornamentals treated with herbicides continue to show no adverse or benficial effects. A study of electrical resistance in selected rose cultivars was completed. This study involved the use of a series of resistance readings obtained from over wintering rose canes, varieties Matterhorn, Bewitched and Summer Sunshine (Hybrid teas), Queenie Saratoga and Europeana (Floribundas), and Camelot, and Scarlet Knight (Grandifloras), in an attempt to correlate resistance to low temperature injury susceptibility. Resistance readings were obtained with a Boyoucous Model C Bridge. Other observations included: dates of leaf color change, leaf fall, bud development and new leaf appearance. In general it was concluded that there is a positive correlation between electrical resistance and cold hardiness. Results showed that Hybrid Tea varieties were most hardy, followed by Grandifloras, with Floribundas being least hardy. These results correlated with resistance readings obtained. Multiflora cultivars are highly variable in terms of cold hardiness. Evaluation of herbicides for weed control in selected ornamentals was continued this year.

SUPPORTED BY Kansas State Government - Topeka

4.0323, NUT AND TREE FRUIT INVESTIGATIONS

N.W. MILES, Kansas State University, Agricultural Experiment Sta., *Manhattan, Kansas* 66502 (KAN00025)

OBJECTIVE: Field testing of varieties of fruits and nuts to determine adaptability to Kansas, including yielding ability, fruit and nut quality and collection of phenological data. The effect of various chemical growth regulators on fruit set, fruit size, and preharvest drop will be studied.

APPROACH: Comparisons are being made of various apple rootstocks including the evaluation of clonal apple rootstocks for the production of dwarf or semi-dwarf trees. Cultural and fertilization practices for trees fruits to determine the best soil management practices for apples and peaches.

PROGRESS: Excessive atmospheric contaminations of 2 4-D herbicide from a nearby military fort caused excessive and visible damage to fruit crops. Pears were damaged most severely and the cultivar Bartlett was most tolerant of the species. Apples, black raspberries, and pecans showed severe distortion but recovered in later growth. Peaches and other stone fruits, and strawberries were relatively tolerant. Grape buds were at balloon stage at time of contamination and, although damage was serious, vines were not killed. Damaging late spring freezes reduced apple production by 50 per cent and peaches by more than 95 per cent. Golden Delicious, Winesap, Jonathan and Red Delicious apple cultivars ranked highest to lowest in production. Alar at 1500 ppm proved an effective stop-drop spray on Jonathan and Winesap but not Yellow Delicious. It was shown that a John Bean Model C-275 speed sprayer could be converted to 3X and 6X concentration spraying without significant change in spray distribution pattern in 25 year old apple trees. Fall applications of Alar at 5000 ppm, Pensalt TD 692, and TD 6241 did not change the low temperature tolerance of Jonathan or Red Delicious apples or peach in fall or winter. Observations will be made in spring 1969 to determine effects on blossom date and tissue low temperature resistance. Preliminary data on stub-pruning vs. standard pruning indicates that more prunings (total) were removed in stub- pruning and early yield might be reduced slightly (1 yr. croping data). This was generally true for both G. Del. and R. Del., spur type or standard type, and seedling or dwarfing rootstock.

SUPPORTED BY Kansas State Government - Topeka

4.0324, FIELD EVALUATION OF HERBICIDES

O.G. RUSS, Kansas State University, Agricultural Experiment Sta., *Manhattan, Kansas* 66502 (KAN-05-898)

OBJECTIVE: Provide uniform data on crop production and performance when chemical weed control is included as a farming practice. Provide uniform data on the performance of herbicides when they are included as a method of weed control in crop production.

APPROACH: Apply label approved herbicides to study weed control and crop injury in corn, sorghum, soybeans, wheat, and alfalfa. Studies to be conducted at Manhattan, North-Central Field, Cornbelt Field, Newton Field, East-Central Field, and Southeast Kansas.

PROGRESS: Field evaluations were made of label registered and some experimental herbicides for control of annual weeds in alfalfa, wheat, soybeans, corn and grain sorghum. Several herbicides or rate of application will be removed from the evaluation testing and new entries will be added. Alachlor applications to grain sorghum resulted in severe sorghum injury at several locations. Alachlor or combinations containing alachlor will be removed from the 1970 tests. Three methods of applying herbicides, preplant, preemergent, and early post emergent, were included in the evaluation tests. Studies of herbicide persistence in the soil and their influence on subsequent crops were continued. First year data indicate no injury to soybeans and winter wheat grown on plots treated with herbicides on grain sorghum in 1968. On a limited basis, sorghum lines are being screened for resistance to herbicides that will control wild cane. Also, soybean lines are being screened for resistance to atrazine.

4.0325, SORGHUM AND CORN PHOTOTOXICITY PROBLEM AT WICHITA KANSAS

W.H. SILL, Kansas State University, Agricultural Experiment Sta., *Manhattan, Kansas* 66502 (KAN-05-839)

OBJECTIVE: Not Provided.

APPROACH: Not Provided.

PROGRESS: This project supported by the Vulcan Chemical Company was reactivated with the return of a graduate student, Miss Aurora Salazar, from the Philippines, to resume her graduate work at KSU. She is continuing her study of the effects of an isomer of Benzene Hexachloride on the growth and morphology of the sorghum plant, particularly the roots. The present studies are in the preliminary stage.

SUPPORTED BY Kansas State Government - Topeka

4.0326, SOUTHEAST KANSAS EXPERIMENTAL FIELD

J. WINZER, Kansas State University, Agricultural Experiment Sta., *Manhattan, Kansas* 66502 (KAN-SEK)

OBJECTIVE: Improve horticultural production in Southeast Kansas by determining those crops and practices which will best suit the ecological and economical situation. Research in pecan production will be of major concern. The best possible propagation, cultural and management methods will be sought for both the existing native pecans and the planted pecan groves. The best adapted pecan varieties are selected native nuts will be determined. Some walnut investigations will also be carried out, as will studies of adaptation and management of tree fruits, small fruits, vegetables, ornamentals and forest species.

APPROACH: The work planned will include thinning, fertilization, intercropping, pest controls, pruning and managment practices for existing native pecans. Propagation techniques will be studied as they apply to topworking native trees and grafting nursery trees. Rootstock investigations will apply to both nut and fruit trees. Research into appropriate varieties or species as well as cultural studies will be carried out to a lesser extent with tree fruits, small fruits, vegetables, ornamentals, and forest trees.

PROGRESS: Herbicide evaluation trials were initiated in 1968. Preemergent chemicals were combined with paraquat and dalapon and applied post-emergent to non-bearing Peruque trees. Observations included toxicity to pecan trees and weed control. Post-emergent applications to native trees included 5 pre-emergent herbicides combined with dalapon or paraquat. Single and split applications of paraquat alone were also evaluated for weed control. Total weed growth was reduced most by paraquat treatments applied 4/25 and 6/26. No injury was observed from any herbicide treatment. In all treatments weed residues were present which would interfere with mechanical pecan harvesting equipment. Pecan samples were collected for residue analysis. Subsurface drainage was found to be beneficial to newly set nursery trees; trees growing in drained soil made about twice as much growth as those in undrained soil. A replicated planting of northern hardy pecan cultivars made in 1964 is making excellent growth; a few trees produced nuts this year. A positive response

to thinning and the application of either 500 or 1000 pounds of ammonium nitrate per acre continues to be noted.

SUPPORTED BY Kansas State Government - Topeka

4.0327, WEED CONTROL IN AGRONOMIC CROPS
J.F. FREEMAN, Univ. of Kentucky, Agricultural Experiment Sta., *Lexington, Kentucky* 40506 (KY00164)

OBJECTIVE: Attempt to discover new weed control principles. Develop chemical, cultural, biological and ecological and combination methods to control weeds in agronomic crops. Determine effects of environmental and edaphic factors on response of these crops and associated weeds to weed control treatments.

APPROACH: Field Plot evaluation studies of promising herbicides will be conducted on corn, soybeans, tobacco and sorghum to determine tolerance of the crop and response of various weeds to preplanting, preemergence, postemergence or post transplanting treatments. Methods of placement of the herbicide with relation to the soil surface in preplanting or preemergence applications, time of treatment in relation to planting or transplanting of the crop, and directional spraying in late post emergence applications will be investigated for purposes of altering the effects of the herbicide on crops, weeds, and soils. Bioassay techniques will be used in greenhouse and laboratory studies of persistence and movement in the soil of selected long-residual herbicides in relating soil characteristics to phytotoxicity in various crops that might follow the treated crop under field practices.

PROGRESS: 82 herbicides applied at various rates and in different combinations on corn, soybeans, tobacco and alfalfa. Since fall panicum (Panicum dichotomiflorum) has become an extremely serious pest in corn and soybeans, one of the major emphasis was to concentrate on obtaining satisfactory herbicide treatment to control this weed. Four herbicides, simazine, atrazine, primazine (atrazine prometryne) and alachlor were applied to minimum tillage corn as pre-emergent treatments. Simazine at 4 lb/A gave significantly greater control of fall panicum, than the other treatments. Atrazine 1 3/5 lb/A simazine 4/5 lb/A, atrazine 4 lb/A, simazine 3 lb/A, primaze 2 lb/A and alachlor 2 lb/A gave slightly less fall panicum control. Although the control of fall panicum was slightly less with these herbicides than with simazine, there was no significant reduction in yield.

SUPPORTED BY U.S. Dept. of Agriculture

4.0328, WEED CONTROL IN HORTICULTURAL CROPS
L. STOLTZ, Univ. of Kentucky, Agricultural Experiment Sta., *Lexington, Kentucky* 40506 (KY00563)

OBJECTIVE: Develop effective and practical methods of weed control in horticultural crops in Kentucky. Evaluate the physiological effect of herbicides on horticultural plants and on weeds.

APPROACH: Studies will be made in the field and in the greenhouse and laboratory, on fruits, vegetables, and ornamentals, and on turf for controlling lawn weeds. Standard techniques and equipment will be used, including replicated, randomized, complete block design. Study of effects of environmental conditions on the phytotoxicity of various herbicides will be included.

PROGRESS: A degree of fall weed control was accomplished in tall bearded Iris with Enide, Treflan, Simazine and Sesone but recommended rates for field application did not provide satisfactory weed control. Relative tolerance of Iris to several herbicides at higher rates was determined. Simazine at 100 ppm did not stop growth but produced tip burn of the leaves within four weeks. Plants remained alive but ceased growing after treatment with Enide and Treflan at 100 ppm. Other herbicides that were tested killed the plants, some herbicides at rates as low as 10 ppm. Simazine, Treflan and Enide are being applied at rates ranging from 4 to 20 pounds per acre on Iris grown in soil to determine their tolerance to these herbicides over a longer period of time. Hydrogen bonding of 2,2-dichloropropionic acid (dalapon) to N-methylacetamide as a protein was studied using infrared spectra. Changes in spectra indicated that the dalapon carboxyl-OH, hydrogen bonds significantly to the model amide carbonyl group. According to this indication, the dalapon molecule must not be ionized to be active. Expected predominance for ionized dalapon molecules at the pH of plant sap explains the high rates of application of this herbicide needed for producing damage in plant tissue.

SUPPORTED BY U.S. Dept. of Agriculture

4.0329, CONTROLLING THE RESPONSES OF CROP AND WEED PLANTS TO HERBICIDES
J.G. GOSSELINK, Louisiana State University, Agricultural Experiment Sta., *Baton Rouge, Louisiana* 70803 (LAB01205)

OBJECTIVE: Increase efficiency and lower herbicide residue by timing applications to coincide with peaks of sensitivity of the plant. Increase specificity of herbicide action by differential response to time of application. Increase rate of detoxification of herbicides by timing application to optimum time in the diurnal metabolic cycle. Control plant growth by modification of the normal production of growth regulators.

APPROACH: Cotton, soybean and weed seedlings will be treated with herbicides at different times in a 24-hour cycle. Response will be measured and correlated with normal rhythmic metabolic changes and leaf movements. Samples of treated and untreated plants taken over 24-hour periods will be analyzed for auxins to correlate growth with rhythmic auxin production, and to study the influence of herbicides on this rhythmic production.

PROGRESS: A diurnal rhythm of susceptibility of cotton and soybean seedlings to a number of different herbicides was clearly shown (Gosselink & Standifer, 1967b). Seedlings are more susceptible to equivalent applications of herbicides in early daylight hours than at other times. Response is not considered endogenous, since it was not observed under constant light and temperature conditions. Existence of a metabolically mediated circadian rhythm of absorption of inorganic P was established in Euglena. Passive absorption of P also showed a tendency to vary in a circadian manner, but differences were not statistically significant. This means, if translation of higher plants is valid, that while metabolism undoubtedly varies diurnally and could thus influence herbicide sensitivity, there is no strong evidence that diurnal changes in physical structure of the membrane allows changes in passive movement into and out of cells. Results of this project indicate the practical application of the work is questionable. Project is terminated in favor of more urgent problems.

SUPPORTED BY U.S. Dept. of Agriculture

4.0330, THE EFFECT OF CHEMICALS USED IN AGRICULTURE ON THE SOIL MICROFLORA
A.D. LARSON, Louisiana State University, Agricultural Experiment Sta., *Baton Rouge, Louisiana* 70803 (LAB00837)

OBJECTIVE: Determine the effect of herbicides, pesticides, defoliants, etc., upon the microorganisms present in the soils of Louisiana.

APPROACH: Studies are being made with the mixed microflora of the soil and with pure cultures of Nitrobacter to observe the possible toxicity of the older herbicides dalapon and the newer fenac upon the processes of nitrification, i.e., the oxidation of ammonia to nitrites and the subsequent oxidation of nitrites to nitrates. The study is utilizing soil perfusion units wherein the perfusate bearing the substrate and the toxic agent are passed over the organisms in a column of soil. The degree of toxicity is evaluated by the quantitative determination of nitrite; by the appearance of it in the oxidation of ammonia and by its disappearance in its oxidation to nitrate.

PROGRESS: The research during the past year has been concerned with the effect of two systemic fungicides, benomyl (1-(butylcarbamoyl)- 2-benzimidozole carbamic acid, methyl ester) and Vitavax (2,3-dihydro-5- carboxanilido-6-methyl-1,4-oxathiin) on microorganisms. Benomyl was quite specific in that it inhibited the growth of fungi and yeast, but not bacteria. It inhibited oxygen uptake by eucaryotic but not procaryotic cells. Benomyl was shown to inhibit oxidation by yeast mitochondria but not the action of enzymes of glycolysis. Yeast grown in the presence of benomyl possessed abnormal mitochondria. It seems that benomyl is an inhibitor of mitochondrial activity and formation and therefore is most active on eucaryotic cells. Vitavax has growth inhibitory effects on fungi and some bacteria. Studies with

mitochondria prepared from Neurospora crassa showed that Vitavax is a potent inhibitor of mitochondrial oxidative activity. The observed results may explain the mode of action of Vitavax on microbial cells. However, Vitavax was shown to be a potent inhibitor of oxidative activity of rat mitochondria and mammals are considered to be quite insensitive to the fungicide. From our studies during the past year we have obtained evidence that two systemic fungicides have a marked inhibitory effect on mitochondrial oxidative activity. This inhibitory effect may be the primary mode of action of systemic fungicides.

SUPPORTED BY U.S. Dept. of Agriculture

4.0331, FUNDAMENTAL STUDIES ON WEED CONTROL
W.C. NORMAND, Louisiana State University, Agricultural Experiment Sta., *Baton Rouge, Louisiana* 70803 (LAB00971)

OBJECTIVE: Study mechanism of action of herbicides in plants. Evaluate effects of herbicides on plants under varying environmental conditions. Evaluate effects of weed competition on plant growth and development.

APPROACH: Studies will be made on the physiology of cotton and weed plants after herbicidal treatment. Temperature-moisture interactions will be studied under controlled conditions in the greenhouse and laboratory, as well as under semi-controlled conditions in the field. Greenhouse and laboratory studies will be made on effects of weed competition.

PROGRESS: Studies of Sido species in Louisiana have been continued. Though various ecotypes were found, only two species, S. rhombifolia and S. spinosa have been identified. There was evidence that the latter species was more resistant to postemergence applications of diuron, fluometuron, or prometryne which may have been due to less stem absorption than in the other species. No morphological evidence was found to explain this difference. Several methods for breaking dormancy of Sida seed have failed, but one compound which releases ethylene did improve the germination of apparently dormant seed. Tests were conducted to determine whether combinations of pesticides applied as seed treatments or preemergence sprays might interact to affect the response of cotton plants. Eight herbicide combinations were evaluated in all combinations with a systemic fungicide and a systemic insecticide. No responses could be ascribed to interaction of these pesticides, though previous observations of stand improvement in herbicide treated plots when a fungicide is used were supported. Seed and seedlings from these plots will be evaluated to seek possible effects on the progeny. A study of mitotic anomalies of excised cotton roots grown in cultures containing nitralin revealed that tissue cultured at 15 C was more subject to such anomalies than was tissue grown at 20 C. A slight increase in the evidence of atypical mitotic figures was also noted in the controls at the lower temperature.

SUPPORTED BY Louisiana State Government

4.0332, INSECTS & MITES ASSOCIATED WITH GRASSES & PLANTS, THEIR IMPORTANCE & MEANS OF CONTROL OF PESTIFEROUS SPECIES
A.D. OLIVER, Louisiana State University, Agricultural Experiment Sta., *Baton Rouge, Louisiana* 70803 (LAB00744)

OBJECTIVE: Determine the economic injury caused by mites & insects & methods for controlling them. Evaluate the role of beneficial species associated with pest species on ornamentals. Study methods of possible cultural practices which increase or reduce pest problems as related to nursery operations. Determine the phytotoxic effects of promising & recommended insecticides & acaricides on growth, grafting & rooting success of plants treated for pest control. Identify beneficial or harmful effects of insects on Christmas tree production.

APPROACH: Basic biological studies of insects & mites will be conducted by maintaining cultures in the laboratory. Effects of photoperiod & temperature gradients on reproduction & susceptibility to chemicals will be determined by holding the cultures in bioclimatic cabinets under different treatment regimes. Field control work will be done at outfield nurseries. Chemical control experiments will be conducted using randomized block designs. Biological control agents will be studied as pest populations increase & decrease. Identifications will be made by using departmental collections, taxonomic keys & national museums. Cultural control will be studied in cooperation with nurserymen. Because of the variation in methods of plant propagation much can be learned which will be helpful in formulation of pest control recommendations. Efforts will be directed toward determining factors which contribute to development of injurious pest populations.

PROGRESS: Chrysanthemums infested with the two-spotted spider mite, a looper, P. includens, bollworms, fall armyworms, southern armyworms, aphids and flower thrips can be protected with proper applications of Lannate at 1 tbsp/5 gal. water and Azodrin, Acarol or Supracide at 1 tbsp/gal of water. Phytotoxicity was not apparent at these rates of application to foliage or flowers. DiSyston 10% G. applied at 1 lb active/1000 sq. ft. of container azaleas gave complete protection from azalea leaf miner, privet mite, southern red mite and a two-spotted mite, Eotetranynchus clitus for 4 months. Field applications at 6 lbs/acre gave control of the southern red mite on azaleas and Japanese holly. Cygon at 1 qt of 2E/50 gal. water gave good control of tulip tree scale on magnolia.

SUPPORTED BY Louisiana State Government

4.0333, STATE WIDE WILDLIFE INVESTIGATIONS
L.D. SOILEAU, State Wildlife & Fish Comm., *New Orleans, Louisiana* 70130

Objectives: To determine if sprouts produced by 2-4-5-T treated browse species retain the herbicide and if so, the effect it has on their palatability.

Procedure: On the Red Dirt G. M. A. browse plants will be treated by burning, cutting and the application of herbicide on deer range where cattle are excluded. Each treated area will be approximately an acre in size. Sprouts produced by each treatment will be examined to determine if those produced by plants treated with herbicide are used by deer at the same rate as sprouts produced as a result of burning and cutting. Sprouts will be chemically analyzed to determine if herbicide is retained. Upon receipt of analysis, a completion report will be prepared.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0334, INSECTS AFFECTING THE APPLE
L.W. BOWLANGER, Univ. of Maine, Agricultural Experiment Sta., *Orono, Maine* 04473 (ME00188)

OBJECTIVE: Control of apple maggot and other pests through chemosterilization. Introduction of predatory parasitic species into orchards devoid of such beneficial forms; subsequent manipulation to achieve integrated control. Changes in present methods of insecticide applications to reduce costs and environmental contamination. Reinforcement of presently available biological knowledge with particular emphasis on behavioral aspects.

APPROACH: Laboratory and field studies will determine acceptability of candidate chemosterilants and feasibility of releasing sterile males into low density field populations. Attractant-sterilant combination will also be evaluated. Parasitic/predatory species will be collected in unsprayed locations and released into commercial orchards where modified chemical programs will be employed. Changes in dosage rates, application patterns, and timing sequences will be used to obtain information on possible reduction in costs and contamination with practical control levels. Ecological and behavioral information will be recovered through sustained and thorough conservations on major pests.

PROGRESS: Apple maggot adult emergence was relatively near normal in terms of initial appearance, peak emergence, and final date of activity. Commercial control efforts were generally excellent with but few occurrences of slight infestation; the latter, in most cases, are judged to have resulted from inadequate coverage and inappropriate intervals between spray applications. In control trials, Lannate and Imidan exhibited acceptable effectiveness under infestation levels comparable to commercial levels. In trials conducted under extreme infestation pressure, Gardona and VCS-506 showed strong capabilities and confirmed their value in normal requirement situations. In plum curculio control experiments, Guthion was considerably more effective than Monitor, the only other compound of comparable value.

Torak, N- 2596, and VCS-506 permitted excessive injury on harvested fruit. European red mite studies confirmed the relatively long developmental periods required for incubation and immature form progress. Fecundity and egg hatch appear to be operating at normal levels.

SUPPORTED BY U.S. Dept. of Agriculture

4.0335, ARSENIC STUDIES WITH BLUEBERRIES AND POTATOES

W.J. KENDER, Univ. of Maine, Agricultural Experiment Sta., *Orono, Maine* 04473 (ME00203)

OBJECTIVE: Determine the arsenic content in blueberry and potato soil, plant, fruit and tuber tissue and the rate of absorption, translocation, and accumulation of arsenic in plant tissue. Study the effect of arsenic toxicity on the growth, chemical composition, and physiology of the blueberry and potato.

APPROACH: The study will be conducted in five general phases, including field surveys, greenhouse sand and soil cultures, greenhouse toxicity experiments, and physiological studies of plant responses to applied arsenic. Similar experiments will be conducted on both blueberries and potatoes.

PROGRESS: During the period January to June, 1968 data on the physical and physiochemical changes found to occur in blueberry fruit were evaluated. These changes were used to identify and characterize the development, maturation, ripening and senescence stages of the fruit. Calcium arsenate and various growth regulators were found to disrupt the normal pattern of fruit development resulting in inhibition of enlargement, color development, and respiration. This information will serve as a basis for the evaluation of pre- and post harvest practices for future research.

4.0336, EFFECTS OF NUTRITIONAL LEVELS ON ORGANOLEPTIC QUALITY OF FRUITS AND VEGETABLES

E.F. MURPHY, Univ. of Maine, Agricultural Experiment Sta., *Orono, Maine* 04473 (ME00162)

OBJECTIVE: Investigate effects of plant nutrition on flavor and texture of fruits and vegetables. Determine the effect of maturity and storage on sensory quality. Investigate relation of physical and chemical measurements to sensory ratings in fruits and vegetables. Investigate effects of pesticides and/or other chemicals on flavor and texture quality.

APPROACH: Apples from trees differing in nutritional status are being evaluated for flavor and texture preference by taste panels, with an attempt to correlate differences with physical and chemical characteristics e.g. acidity, total solids, sugars. An investigation is being pursued to determine mealiness differences (by taste panel) or certain varieties of processed potatoes as related to chemical components.

PROGRESS: Maine lowbush blueberries: texture preference of pies with frozen stored berries with fillings containing 1, 2, and 3 tablespoons (T) cornstarch per pie were judged by a 31-member panel. The 2T filling was significantly preferred, and the 1 and 3T were not different. The same test with fresh berries (30 judges) showed the 2T texture to be significantly preferred to the others and 1T significantly better than 3T. Flavors of pies (frozen berries) with 3/4 and 1 cup sugar with and without 1T lemon juice were not different as judged by a 32-member panel.

4.0337, AN INVESTIGATION OF THE EFFECTS OF DDT AND OTHER CHLORINATED HYDROCARBONS ON THE GROWTH OF EURYHALINE MICROALGAE

R.L. VADAS, Univ. of Maine, School of Agriculture, *Orono, Maine* 04473

The proposed research plan involves laboratory studies directed at determining the effects of DDT and other chlorinated hydrocarbons on the growth and photosynthesis of euryhaline microalgae. Other pesticides will be investigated.

The main approaches to these problems are as follows: Growth studies will be conducted in light and temperature controlled growth chambers. Periodic cell counts will be used to determine growth rates at varying pesticide concentrations. Photosynthetic rates will be determined by changes in CO_2 concentrations using an infrared gas analyzer. Resistance to pesticides will be determined through long term growth studies at varying pesticide concentrations.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

4.0338, QUALITY AND NUTRIENT COMPOSITION OF FOODS TREATED WITH PESTICIDES

E. DAWSON, U.S. Dept. of Agriculture, Human Nutrition Research Div., *Beltsville, Maryland* 20705 (HN3-29A)

OBJECTIVE: See Accession No. 0015593.

APPROACH: See Accession No. 0015593.

PROGRESS: Atrazine had an effect at the 1% significance level on the fructose content of lochief corn, whereas there was no significant difference between replicates. The fructose content was higher which agrees with our findings previously reported that the carbohydrate content of peaches was also higher after herbicide treatment. There was no difference in ash content among controls or treatments, probably indicating that the field has been fertilized so frequently that there is no difference in the soil gross mineral content. The atrazine treatments had no effect on nitrogen content. In the case of the mineral analyses of apples and asparagus from Rutgers University, the calcium content of the 1966 herbicide treated apples was lower than that of the clean cultivated apples. In view of the conflicting data on mineral content of apples and asparagus under herbicide treatment, it would be difficult to conclude that the atrazine had any effect on the mineral uptake of the corn. More needs to be known about the metabolic effects of herbicides. Herbicide treatment had no consistent effect on the mineral content of the asparagus crops.

SUPPORTED BY U.S. Dept. of Agriculture

4.0339, TREATMENTS FOR CONTROL OF POSTHARVEST ROTS AND FUNCTIONAL DISORDERS IN APPLES

R.E. HARDENBURG, U.S. Dept. of Agriculture, Market Quality Research Div., *Beltsville, Maryland* 20705 (HC-2)

OBJECTIVE: Study the compatibility of fungicides and scald inhibitors applied together as postharvest treatments to prevent decay and scald of stored apples and pears grown in the East.

APPROACH: Heated and non-heated solutions and suspensions of fungicides (Benlate, TBZ, etc.) and scald inhibitors (ethoxyquin and diphenylamine) will be evaluated for their combined effectiveness. Fruit of different maturities, especially the injury-sensitive variety Golden Delicious, will be tested and the length and temperature of the dip treatments varied to find safe and effective preservative treatments. The possibility that heated chemical solutions at low concentrations may be as effective as higher concentrations at ambient temperature will be investigated.

PROGRESS: Eastern apples. Postharvest dips (3 min.) of heated (113 F.) suspensions (100 or 500 ppm) of benomyl or TBZ effectively controlled blue mold rot in inoculated Golden and Red Delicious apples during 2 months at 32 F. followed by 1 week at 70 F. Comparable tests with heated (113 F.) tap water did not control decay. Heated fungicides controlled decay in either punctured or bruised apples, whereas unheated fungicides controlled decay only in punctured apples. More fungicide was deposited on apples dipped in heated than in unheated fungicide suspension. Both fungicides at 1000 ppm were compatible with commercial scald inhibitors (2700 ppm ethoxyquin or 2000 ppm diphenylamine). Combination dips of fungicide and scald inhibition were not phytotoxic to Red Delicious or Stayman apples stored 5 months at 32 F. followed by 1 week at 70 F. Effectiveness of the fungicide-scald inhibitor combinations was not affected. Eastern pears. A 10-second dip in a 500 ppm suspension of either benomyl or TBZ greatly reduced blue mold rot in stored Bartlett, Magness, and Moonglow pears. Pears treated with either chemical developed less decay in punctured or bruised areas and in the stem-end than comparable pears dipped in tap water. The fungicides did not control Alternaria tenuis rot.

4. PESTICIDES

SUPPORTED BY U.S. Dept. of Agriculture

4.0340, MECHANISMS OF HERBICIDE ACTION

J.L. HILTON, U.S. Dept. of Agriculture, Crops Research Division, *Beltsville, Maryland* 20705 (0710-01-02)

OBJECTIVE: Discover modes of herbicide action in plants; characterize effects of herbicides on plant nucleic acids, protein and energy synthesis and elucidate effect of herbicides on specific biochemical processes and growth.

APPROACH: Correlate the effects of herbicides on metabolic processes with growth and physiological responses. Isolate, characterize, and determine functionality of specific plant nucleic acids and precursors affected by herbicides using radioisotopes and biochemical techniques. Use inhibition of carbon dioxide fixation to determine factors affecting speed of herbicide action and plant recovery. Use herbicide analogs to distinguish multiple modes of action. Evaluate herbicide-metabolite antagonisms on growth of organisms to detect new sites of herbicide action.

PROGRESS: Asymmetrical triazine herbicides inhibit photosynthesis. They are detoxified by plants. Inhibition of photosynthesis by pyridazinone herbicides is delayed by absorption or translocation barriers which do not affect speed of action of other photosynthesis inhibiting herbicides. A method for measuring ATP in vivo was developed. Chloropropham reduced ATP levels in Chlorella more effectively than it inhibited photosynthesis. Diuron inhibited photosynthesis more effectively than it affected ATP levels.

SUPPORTED BY U.S. Dept. of Agriculture

4.0341, FACTORS INFLUENCING PLANT RESPONSES TO HERBICIDES

L.L. JANSEN, U.S. Dept. of Agriculture, Crops Research Division, *Beltsville, Maryland* 20705 (0710-01-39)

OBJECTIVE: Discover and characterize chemical, physiological, and ecological factors which influence sorption, movement, and action of herbicides in plants; and develop safer and improved uses of herbicides for control of weeds in agronomic crops.

APPROACH: Investigate the effects of spray adjuvants, physiological status, and morphological-anatomical features of plants on the response of plants to herbicides.

PROGRESS:

SUPPORTED BY U.S. Dept. of Agriculture

4.0342, EFFECT OF PCNB ON PALATABILITY AND COMPOSITION OF POTATOES

J.P. SWEENEY, U.S. Dept. of Agriculture, Human Nutrition Research Div., *Beltsville, Maryland* 20705 (HN3-31)

OBJECTIVE: Determine the effects of Pentachloronitrobenzene (PCNB), a soil fungicide, on palatability and composition of potatoes.

APPROACH: Samples of untreated controls and of potatoes grown in PCNB-treated soil will be evaluated at the start of storage and after storage at room temperature and at 55 F. Free phenols, tyrosine, ascorbic acid, starch, sugars, selected enzymes, specific gravity, and shear strength will be determined. Structure will be examined histologically. Panel evaluations of color, texture, and flavor will be made on baked and steamed potatoes.

PROGRESS: Pentachloronitrobenzene (PCNB), a soil fungicide, is effective against potato scab and black scurf. Potatoes grown in soil treated with PCNB at 50 pounds per acre were lower in free tyrosine content and showed less enzymic browning than did control potatoes. When the treatment was 25 pounds per acre, tyrosine and enzymic browning were also lowered. However, the decreases were not as great as those obtained when the treatment was 50 pounds. PCNB at 50 pounds per acre appeared to have some adverse effects on flavor and odor, but effects could be detected only by a judge very sensitive to them.

SUPPORTED BY U.S. Dept. of Agriculture

4.0343, CHEMICAL CONTROL OF ORCHARD INSECTS

W.E. BICKLEY, Univ. of Maryland, Agricultural Experiment Sta., *College Park, Maryland* (MD-H-048)

OBJECTIVE: Test two types of spray equipment and one dust machine. Both machines are of the air blast type; the dust machine is designed to apply both charged and uncharged particles of dust.

APPROACH: Various spray and dust formulations will be tested with these machines. Records will be kept on the control of codling moth and other apple pests. Observations made on the phytotoxicity to both fruit and foliage.

PROGRESS: A twelve acre block of York Imperial and Rome Beauty apples in a 300-acre abandoned orchard was used to compare a full strength and a 3/4 strength program in each of four concentrates, namely 3X, 10X, 33X and 66X. Fruits examined at harvest from the full strength program ranged from 92% to 99% clean while those from the 3/4 strength program ranged from 95% to 98% clean. The unsprayed check had only 7.8% clean fruit. There was no significant difference in the control of pests between any of the concentrates or between the full and 3/4 strength programs used on these tests. This confirmed our finding during the past 7 years that the high concentrates were equally as effective in controlling orchard pests as the standard 3X concentrates now being used. It also showed that with high concentrate sprays the materials going into the tank can be reduced as much as 25%. A 2-acre block of Stayman Winesap apples was used to test the effectiveness of 13 new acaricides in summer applications. Eight materials were found to be as effective in controlling mites as the standard acaricides now being used. A re-examination was made of the armored scale insect genus Melanaspis in North America which resulted in the recognition of 2 new species and the resurrection of one synonym. Detailed life history observations were made on the gloomy scale (M. tenebricosa) and obscure scale (M. obscura).

SUPPORTED BY Maryland State Government

4.0344, HERBICIDE CHARACTERISTICS AND EFFICIENCY IN CORN AND SOYBEANS

G.W. BURT, Univ. of Maryland, Agricultural Experiment Sta., *College Park, Maryland* (MD-B-094)

OBJECTIVE: Study the effects of formulations, carriers, and methods of application on efficiency; the effects of environment on release and action of granular herbicides; relate prior weed control practices to weed populations in succeeding crops of corn and soybeans; and the effectiveness of cultural herbicide combinations.

APPROACH: The effectiveness of promising corn and soybean herbicides such as atrazine, amiben, and D-326 will be compared with special attention to granular formulations made locally. The latter will be studied from the standpoint of synthesis of granules, release of herbicide, and movement away from the particle. Speed of volatilization will be measured by bioassay methods and by the use of radioactive materials. Replicated field plots will be compared with reference to cropping system, herbicide, and the combination of herbicide and cultural practice for weed control in corn and soybeans.

PROGRESS: Volatility of sprayed application of trifluralin was approximately 25% benefin, 12.5% at 50 C from a Lakeland sandy soil at field capacity under controlled laboratory conditions whereas nitralin volatility was negligible. Decreasing soil cation exchange capacity and increasing soil moisture from air dryness to field capacity increased volatility. However, increasing soil moisture above field capacity did not increase volatility. A granular formulation of trifluralin was effective in reducing vapor losses, but volatility of a granular formulation of benefin was similar to the spray application. Increased spectrum weed control was observed with many of the herbicide combinations investigated in corn. Butylate 3 lb/A and butylate plus atrazine 3lb/A 1 lb/A respectively were the only herbicides preplant incorporated to result in acceptable nutsedge control. This combination and other herbicides with CP 50144 were effective on fall panicum and lambsquarter. Butylate preplant incorporated

plus atrazine with oil postemergence was the only combination which was synergistic for nutsedge control. In soybeans, chloroxuron postemergence effectively controlled ragweed which escaped trifluralin, nitralin, and vernolate without reducing soybean yields.

SUPPORTED BY U.S. Dept. of Agriculture

4.0345, PHYSIOLOGICAL AND BIOCHEMICAL MECHANISMS OF SELECTIVITY OF HERBICIDES
G.W. BURT, Univ. of Maryland, Agricultural Experiment Sta., *College Park, Maryland* (MD-B-098)

OBJECTIVE: Study factors affecting the selectivity of herbicides on agronomic crops. These factors include penetration and movement, metabolism and detoxification of herbicides in plants and soils. Investigate the use of herbicide combinations for broadening selectivity and reducing residues.

APPROACH: Factors affecting the selectivity of several new herbicides on agronomic crops will be studied using isotopically labelled herbicides and paper chromatography. The fates of the herbicides will be studied in both tolerant and susceptible plants. Herbicides which inhibit photosynthesis will be combined with ones which inhibit respiration.

PROGRESS: For uptake and distribution experiments using trifluralin-C (alpha,alpha,alpha trifluoro-2,6-dinitro-N, N-dipropyl- p-toluidine), treated seedlings were grown in liquid scintillation vials. This procedure eliminated the loss of that portion of the herbicide which remained on the glass walls of containers used prior to transferring to counting vials. To prevent the rapid loss of the herbicide from the open vial, a mixture of Florisil and Sephedex was added to the water-trifluralin solution at seeding time. Another technique for retaining trifluralin was the placement of 1/4 inch thick foam rubber disks at the bottom of the vials. In orde: to increase the recovery of the labelled herbicide, treated plant material was crushed in a separate scintillation vial and at the same time one gram of Florisil was incorporated. Counting solution added, and counted. A 30 to 40 percent increase in counts was obtained when vials were counted approximately 24 hours after adding Florisil. Trifluralin was also lost when using a flash evaporator to remove excess solvent from plant extracts. This was especially true when water was removed. During the evaporation process, the herbicide apparently vaporized and instead of being carried over in the distillate, it adhered to the surfaces of the condensing column and other glass parts. A foam rubber filter at or near the mouth of the flask containing the evaporating extract, greatly reduced losses.

SUPPORTED BY U.S. Dept. of Agriculture

4.0346, COMPOUNDS IN WEEDS RESPONSIBLE FOR DORMANCY AND THE REDUCTION OF CROP YIELDS
G.W. BURT, Univ. of Maryland, Agricultural Experiment Sta., *College Park, Maryland* (MD-B-115)

OBJECTIVE: Determine the importance of salicylic acid and other compounds in the dormancy of nutsedge tubers. Also to determine the biological significance of toxic compounds excreted by and found in nutsedge, quackgrass and other weeds.

APPROACH: Nutsedge plants will be grown under different conditions of photoperiod, temperature, and gibberellic acid concentrations to induce various degrees of dormancy. Salicylic acid will be spectrophotometrically analyzed to determine if there is a correlation between salicylic acid and dormancy. Toxic excretions will be determined by growing nutsedge in nutrient solution by the split root technique. The growth of a test species will indicate the presence or absence of a toxic exudate. Incorporation of nut dge tissue in soil with subsequent growth of a crop will also be used to determine if nutsedge can reduce yields through the release of toxic compounds. Isolation of these toxins by chromatography will be attempted.

PROGRESS: Studies have been conducted to determine if Johnsongrass rhizomes exude toxic substances. All rhizomes used were collected from the field, selected for uniformity, surfaced sterilized for 2 min. with 5.25% sodium hypochlorite, rinsed with distilled water, cut into pieces containing 2 nodes, and placed in 7 in. plastic petri dishes. These rhizome pieces remained in petri dishes for 1, 3, and 7 days after which they were removed and 20 seeds of the test species were placed in the same petri dish. Percent germination, and shoot and root length were recorded to determine the biological activity of exudates from the rhizome pieces. In studies using 2 rhizome pieces per dish and at room temperature, the response of seedlings to Johnsongrass exudates was found to be very dependent on the species and the plant part being tested. Tomatoes, soybeans, and corn were not effected by Johnsongrass exudates, whereas, only the root growth of millet, cotton, barley, and wheat were reduced by the exudates. Experiments were conducted where the incubation period with rhizome pieces was at 5,24 and 30 C. Toxicity of the exudates was greatest at 5 C. Experiments were conducted using 10 instead of 2 rhizome pieces per petri dish.

SUPPORTED BY U.S. Dept. of Agriculture

4.0347, BIOLOGY AND CONTROL OF ORCHARD INSECTS AND MITES
E.R. KRESTENSEN, Univ. of Maryland, Agricultural Experiment Sta., *College Park, Maryland* (MD-H-099)

OBJECTIVE: Evaluate new insecticides and acaricides for control of orchard insects and mites. Evaluate pesticide extenders. Test new types of concentrate spray equipment. Study life and seasonal histories of insect pests of deciduous fruits and their predators.

APPROACH: Insecticides and acaricides will be tested in low concentrates of 3X with a John Bean 200TR Speed Sprayer and a high concentrate of 33X with an Econ-o-mist. Extenders will be tested at the low concentrate using reduced pesticide rate programs and by lengthening the time between sprays. Summer applications of new acaricides will be tested as dilute sprays only. Percent insect damage at harvest and mite counts during the season will be used to determine effectiveness of control. Records on phytotoxicity and compatibility will be kept. Life history studies will be made in the field and in the laboratory if adequate facilities are available.

PROGRESS: Five new insecticides, Torak, GS-13005, Zolone, VCS-506, and Fundal, were tested for broad spectrum orchard insect control at a 33X concentrate. Zolone, Torak, and GS-13005 were used as the only insecticide from petalfall through 7th cover. Fundal and VCS-406 were used at half strength with lead arsenate from petalfall through 4th cover. Lead arsenate was then dropped and the test materials increased to full strength through 7th cover. All materials gave orchard insect control equal to that obtained with the standard Maryland lead arsenate-azinphosmethyl program applied at a 33X concentrate. Oil applied at a 33X concentrate in delayed dormant controlled San Jose scale, whereas oil at a 66X concentrate did not. No phytotoxicity to fruit or foliage was observed with these materials. Leaf analysis from plots receiving a pesticide extender, Pinolene, Nu-Film 17, throughout the season showed this material had extended the residual life of both Morestan and azinphosmethyl. Residue analysis data for fruit at harvest, however, were inconclusive. No significant difference in insect control was observed between those plots receiving the standard spray program with Pinolene added and those without the Pinolene.

SUPPORTED BY Maryland State Government

4.0348, PESTICIDE RESIDUES IN OR ON RAW AGRICULTURAL COMMODITIES
R.E. MENZER, Univ. of Maryland, Agricultural Experiment Sta., *College Park, Maryland* (MD-H-067)

OBJECTIVE: Investigate residues resulting from the use of pesticides and plant growth regulators applied to plants and animals, determine use with least residue and without undue residues in soil, water, and other parts of the environment. Develop and standardize sampling and analytical methods for the determination of pesticide residues.

APPROACH: Determine the rate and extent of absorption of insecticides by vegetable and forage crops, rate and extent of degradation of insecticides within the plants, period required for the degradation of insecticides, persistence of insecticide within the soil.

PROGRESS: Analyses of soil samples from two different sites to which disulfoton was applied are still being analyzed. The

two soils are of different types: sandy loam and loamy sand. The object of the experiment is to ascertain whether soil type has a marked effect on the rate of degradation in soil. Mocap, O-ethyl S,S- dipropylphosphorodithioate, was applied as a 10% granular formulation at the initial rate of 14.3 ppm to sterile soils in clay pots in which green beans were grown in plant growth chambers. The experiment was conducted in duplicate using both Mocap-ethyl- C and Mocap-propyl- C. The biological half-life of Mocap in the soil varied between 40 and 45 days. This probably represents a maximum half-life to be expected for Mocap in soil since the experiment was conducted in sterile soil under controlled environmental conditions in plant growth chambers. Analyses of commercially frozen samples of squash, carrots, blueberries, turnips, turnip greens, lima beens, green beans, peppers, cauliflower, kale, mustard greens, corn, peas, collards, and spinach revealed no insecticide residues that exceeded tolerances. Canned sweet potatoes were also residue-free. Insecticides found were dieldrin in squash and carbaryl in corn, collards, kale, and green beans.

SUPPORTED BY U.S. Dept. of Agriculture

4.0349, TRANSFORMATIONS OF INSECTICIDES BY PLANTS

R.E. MENZER, Univ. of Maryland, Agricultural Experiment Sta., *College Park, Maryland* (MD-H-085)

OBJECTIVE: Identify the products of degradation of insecticides by plants and determine the quantitative significance of these products; determine the absorption and translocation of insecticides and their degradation products by plants; investigate the mechanism of decomposition of insecticides by plants.

APPROACH: Metabolic pathways of dimethoate in plants vary with the method of application. The metabolic pathways resulting from different methods of application (cut stem, foliar, soil, and plant macerate) will be studied using C -labeled dimethoate (-CH -side chain). Chromatographic methods and chemical degradation utilized to characterize metabolites. Study made of the persistence of the major metabolites. Enzyme systems that accomplished the metabomate results of this research are to more clearly recognize the mode of herbicidal action. This should be much easier if the selectivity of herbicide is studied in closely related plants.

PROGRESS: Treatment of pumpkin plants with 2-chloroethylphosphonic acid (CEPHA) induced a greater production of female flowers, shorter internodes and earlier fruit set while treatment with gibberellic acid (GA) induced a greater production of male flowers, longer internodes and later fruit set. Although CEPHA induced the production of a greater number of female flowers, the bulk of the flowers aborted and only a slight increase in the number of fruits per pumpkin plant occurred. The addition of equal concentrations of CEPHA and GA resulted in pumpkin plants with longer internodes and a greater number of female flowers than the untreated plants, although GA partially overcame the effect of CEPHA. The use of CEPHA to increase yield of pumpkins does not appear to be practical under Illinois conditions. In studies with cabbage cultivars differentially affected by nitrofen, it was found that a dark period prior to nitrofen application increased the susceptibility of the cultivar Rio Verde to nitrofen phytotoxicity. However, the addition of sucrose before or after nitrofen application to either the upper or lower leaf surface protected against injury.

4.0615, RESPONSE OF RATS TO DIETS CONTAINING MULTIPESTICIDE COMPONENTS

W.W. CARLTON, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (IND01553)

OBJECTIVE: Investigations of the physiological response of rats to diets containing multipesticide components when selected trace minerals are fed at marginal, excessive or deficient levels.

APPROACH: Plan and conduct investigations to determine the physiological response of rats to diets containing multipesticide components using at least two of the trace minerals, copper, zinc and/or manganese, fed at excessive, marginal, and/or deficient levels.

PROGRESS: Studies are continuing on the response of rats to a multi-pesticide mixture of DDT, carbaryl, and parathion and diets containing deficient, marginal and excessive concentrations of copper or manganese. An encephalopathy with signs of neurologic disturbance was induced in off-spring of females fed the copper-deficient diet. In a low percentage of offspring of copper deficient groups heart pathology was observed including cardiac hypertrophy with microscopic lesions of mycardial necrosis and replacement fibrosis. The pesticide mixture did not appear to have an adverse effect on the response of rats to the various diets. Further studies will include the histopathologic examination of animals maintained on the experimental diets for 2 years.

SUPPORTED BY Indiana State Government

4.0616, PHYSIOLOGICAL RESPONSE OF FEMALE RATS AND OFFSPRING TO MULTI-INSECTICIDES AND MINERALS

W.W. CARLTON, Purdue University, School of Veterinary Medicine, *Lafayette, Indiana* 47907 (HN2-54(C))

OBJECTIVE: Determine if maternal diets containing multi-insecticides affect reproductive performance of female rats and growth and tissue structure of offspring when level of dietary minerals vary.

APPROACH: Feed female rats an adequate basal diet or modification with or without insecticides and with minerals such as Zn, Mn, or Cu at minimal or excessive levels. Insecticides to include members of DDT, organic phosphate, or dinitrophenol groups at permissible levels. Feed experimental diets from weaning throughout study or only during gestation and lactation. Determine weight gains, weight, number and skeletal development of young at birth and after several months on diet.

PROGRESS: Feeding studies of the first generation offspring fed the diets containing different levels of manganese with and without insecticides have continued for 68 weeks. Data have also been obtained for the first 12 weeks for rats fed diets containing different levels of copper with and without insecticides. Tissues obtained from first generation females fed the copper and manganese diets have been examined grossly and microscopically. Pesticide analysis of tissues from all groups are underway.

SUPPORTED BY U.S. Dept. of Agriculture

4.0617, TRACE LEVELS OF PESTICIDE RESIDUES IN AGRICULTURAL COMMODITIES IN MARKETING CHANNELS

B.J. LISKA, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (IND01427)

OBJECTIVE: Develop methods for preventing and reducing pest damage or pesticide residues in agr. commodities during transportation, processing and/or storage. Develop procedures for the removal, reduction or de-toxification of pesticide residues and conversion products in agricultural commodities. Develop or improve methods for determining pesticide residues in agricultural coomodities in marketing channels. Evaluate costs to implement processing procedures for agricultural commodities to remove, reduce, or de-toxify pesticide residues and/or conversion products. Animal food products with a trace amount of DDT, dieldrin, lindane, heptachlor and endrin will be processed by normal processing procedures. The products will be analyzed for changes in residues during processing and storage. Changes in processing techniques will be made to attempt removal or de- toxification of residues present in the food products.

APPROACH: NOT-PROVIDED

PROGRESS: Research on the effects of heat processing on chlorinated insecticides in animal food products was concluded. The overall results indicated that heat processing does reduce the concentration of chlorinated insecticides especially in spray dried milk, sterilized milk and cooked chicken meat. With some insecticides, as DDT and lindane, virtually 100% of the insecticide was removed by heat processing. Cobalt(60) irradiation of aldrin, dieldrin and DDT in hexane solutions at the 6 megarad level indicated that some insecticide was destroyed and some converted to recoverable breakdown products. One change which occurred was a removal of at least one chlorine molecule during irradiation. There was a temperature effect on the breakdown of aldrin

by cobalt(60) irradiation. Samples irradiated at 30-35 C had more breakdown products than in samples irradiated at liquid nitrogen temperatures. Breakdown products formed from aldrin were effected by the substrate used to carry the aldrin. This effect was related to the number of free radicals formed from the substrate during irradiation. Aldrin dispersed in lard and corn oil was broken down by irradiation the same as when dispersed in hexane.

SUPPORTED BY U.S. Dept. of Agriculture

4.0618, ACCELERATED REMOVAL OF INSECTICIDE RESIDUES

W.J. STADLEMAN, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (IND01423)

OBJECTIVE: Extend present insecticide residue decontamination methods developed with laying hens; develop additional decontamination methods with poultry; adapt methods to other species of farm animals.

APPROACH: Force-molted laying hens contaminated with chlorinated hydrocarbon pesticides will be subjected to factorially arranged dietary treatments. Graded levels of energy, protein, iodinated casein and selected drugs (liver detoxification stimulants) will be administered in the ration. The effect of treatments on the rates of depletion of body fat and egg pesticide residues will be determined. Depletion treatments effective with laying hens will be adapted to, and tested with lactating goats. Effective treatments that do not grossly impair weight gains and feed efficiency in laying hens will be tested on growing swine.

PROGRESS: The DDT residue retention by abdominal adipose tissue was found to be a representative indicator of the DDT residues retained in other tissue lipids. DDT residue retention capacity of abdominal adipose tissue, thigh muscle, and breast muscle tissues was directly related to the lipid content of the tissue. DDT per gram of tissue lipid was slightly higher for muscle tissue lipid than abdominal adipose tissue lipid. A significant (P
05) reduction in retntion of DDT and DDE residues in abdominal fat was observed when activated charcoal was fed to chicks exposed to 0.5 ppm DDT. Charcoal was more effective in reducing residue retention when DDT was added to the ration than when administered by capsule. Dietary charcoal was not effective in reducing residue retention at the 0.1 ppm DDT exposure level. Rate of residue depletion was not affected by feeding charcoal to contaminated chicks for 21 days. DDT did not appear to be associated with the lipoprotein of chylomicron fractions of serum. serum fractions separated.

SUPPORTED BY U.S. Dept. of Agriculture

4.0619, MULTICRITERIAL EVALUATION OF ENVIRONMENTAL PESTICIDES

W.B. BUCK, Iowa State University, School of Veterinary Medicine, *Ames, Iowa* 50010

The principle objective of this research is to develop techniques and criteria for the assessment of subtle effects of environmental neurotoxicants on the central nervous system.

One of the objectives of the proposed research is to determine the lowest exposure level of dieldrin in sheep that will produce the decrements in vigilance and discrimination learning behavior which has been observed in our laboratory. We also intend to investigate the effects of dieldrin on other types of operant behavior in sheep. In addition, we will investigate the neurophysiological mechanism(s) of action of dieldrin in a mammalian (sheep) nervous system, and determine, by means of computer techniques, the relationship between electroencephalographic and behavioral changes observed in sheep following dieldrin exposure.

A major objective of the project is to develop procedures and techniques for obtaining knowledge of the effects of certain key environmental pollutants, especially neurotoxicants, on the central nervous system of man and animals. It is felt that this will provide a more scientific basis for establishing residue tolerance levels.

4.0620, METABOLIC STUDIES OF INSECTICIDES

UNKNOWN, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010 (IOW01351)

OBJECTIVE: Not Provided

APPROACH: Not Provided

PROGRESS: Purification and characterization of organophosphate- metabolizing enzymes are being studied in vitro in rat liver microsomes by means of several methods including sonication, centrifugation, column chromatography, and fractionation by ammonium sulfate and detergents. The first main effort was directed toward delineating the solubilization of enzymes from microsomal membranes. Secondly, attempts were made to study the properties of the enzymes. Thirdly, attempts are being made to resolve a microsomal suspension into two components, cytochrome P-450 and NADPH-cytochrome c reductase. These two components may be related to organophosphate metabolism.

4.0621, MECHANISM OF ACTION OF HALOGENATED HYDROCARBON FUMIGANTS ON ANIMALS

A. BONDI, Volcani Inst. of Agric. Res., *Rehovoth, Israel* (SP70(A10-MQ-8(A)))

OBJECTIVE: Determine acute and chronic poisoning of animals of carbon tetrachloride and ethylene dichloride and compare with known results of ethylene dibromide.

APPROACH: Three phases to study: Amount of residue of grains of ethylene dibromide (EDB), ethylene dichloride (EDC) and carbon tetrachloride (CC1(4)) during airing following fumigation by gravity penetration, forced recirculation and vacuum fumigation on laboratory and semi-commercial scale chronic poisoning of rats, chicks, laying hens and sheep with EDC and CC1(4) in long term feeding trials and biochemical mechanism of the poisonous action including comparison of the detoxification mechanism in chicks and rats and causes of disturbances in egg laying produced by EDB. Two leads to be followed on the latter study are differences in egg yolk proteins and damage to ovarian follicular membrane.

PROGRESS: Fumigations with carbon tetrachloride (CTC) were conducted by gravity penetration and recirculation. Only by the second method were homogeneous residues obtained. Preliminary experiments with forced airing did not result in efficient desorption. Samples of fumigated wheat still contained up to 10 p.p.m. after a year of storage. Baked bread contained less than 0.5 p.p.m. Mash fumigated at different levels of CTC was fed to growing male and female rats and lambs to test effects on growth rate and sexual development. Although the amounts fed to rats were small (up to 1 percent of the LD(50)) and only a slight effect on growth rate was observed, the total fat and triglyceride content of the livers increased significantly in all animals, except those fed at 150 p.p.m. The sexual development of male rats seemed unaffected. Lambs were more susceptible to the CTC. Restricted feed intake, leading to cessation of growth, occurred when there was a level of 100 p.p.m. At a level of 35 p.p.m., growth was proportional to the intake. Only when 20 p.p.m. was present in the mash were food consumption and growth similar to those of the controls. Blood transaminase activity and liver fat levels were normal in all treated lambs, indicating no symptoms of CTC poisoning. In contrast to previous findings with bulls, mature ram spermiogenesis was not affected by ethylene dibromide. Further experiments with laying hens confirmed that diminished ovarian follicle growth is the result of ethylene dibromide action.

4.0622, INVESTIGATIONS OF WILDLIFE MORTALITY RELATED TO PESTICIDES

S.W. CAPEL, State Forest. Fish & Game Com., *Pratt, Kansas* 67124

Objective: To determine the role of pesticides as a causative factor in mortalities of wildlife in Kansas and to provide for coor-

dination and liaison with various Federal, State and County agencies regarding pesticide use problems.

Procedures: 1. Inspect areas of reported wildlife mortalities suspected of being caused by pesticides. 2. Determine probable extent of mortality through interviews with persons in area and through ground checks to verify presence and density of dead wildlife. 3. Estimate, if possible, number and species affected. 4. Determine recent and long term pesticide use on area through interviews with landowners and commercial pesticide applicators. 5. If cause of mortality cannot be logically attributed to a non-pesticide cause, specimens of dead and living animals in the area will be collected for analysis. 6. Pesticide residue analyses will be conducted using standardized analytical techniques. Analyses will be performed by private laboratories, Kansas State Board of Health, various State universities, the Bureau of Sport Fisheries and Wildlife, or other agencies as the particular situation warrants and as specific contractual agreements can be arranged. 7. Analyze the data and information obtained through procedures 1-6 and if possible; 1) indentify the pesticide causing the mortality, 2) determine the source or possible sources of the lethal pesticide and 3) make appropriate recommendations of similar occurrences. 8. Coordination and liaison: a) Represent Director on the Pesticide Advisory Board, State Marijuana Control Steering Committee and other similar groups as assigned, to provide guidance in regard to wildlife-pesticide problems, b) act as spokeman for the Commission in liaison with various Federal, State and County agencies concerned with pesticides and their proper use, and c) develop pesticide use recommendations for land managed by this agency.

4.0623, EFFECTS OF PESTICIDES ON MICROORGANISMS IMPORTANT TO THE DAIRY INDUSTRY

B.E. LANGLOIS, Univ. of Kentucky, Agricultural Experiment Sta., *Lexington, Kentucky* 40506 (KY00417)

OBJECTIVE: Compare the effect of organochlorine pesticides on the growth and metabolic activity of microorganisms in media with and without casein. Determine and characterize the mode of action of organochlorine pesticides in inhibiting growth and metabolic activity of microorganisms.

APPROACH: (a) Milk and broth media will be used to determine the effects of organochlorine pesticides on the growth and metabolic activity of microorganisms isolated from milk as well as those used in the manufacture of various food products. The microorganisms will be divided into groups based on their resistance or sensitivity to pesticide inhibition in order to determine if inhibition is at the species or genus level and if dependent on a particular pesticide. The metabolic activity affected as well as the fate of the pesticide during the growth period will be determined. (b) Sensitive microorganisms from (a) will be used to characterize the mode of action involved in the inhibition. Studies will be made to determine if inhibition is due to action of the pesticides on some structural organization of the cell or to reaction with participants in enzyme systems.

PROGRESS: Species of bacilli are capable of degradating DDT to at least seven metabolites. These bacteria are much more efficient in this degradation than are the coliform bacteriform. The coliform bacteria degradate DDT more effectively anaerobically than aerobically. The pathway involved in the degradation of DDT is presently under study. Heptachlor and heptachlor related pesticides inhibit the growth of Staphylococcus aureus. The greater the level of pesticide the more severe the inhibition. Increasing the number of bacteria added to the medium will reduce to a limited degree the amount of inhibition. The inhibition is completely removed when casein is added to the growth medium. Results appear to indicate that pesticides in milk are tied up by casein and thus unavailable for degradation by bacteria and also unable to inhibit the growth of bacteria.

4.0624, CARCINOGENESIS BIOASSAY OF PESTICIDES AND OTHER ENVIRONMENTAL AGENTS

H.P. BURCHFIELD, Gulf South Research Institute, *Baton Rouge, Louisiana* (NIH-70-2210)

Independently and not as an agent of the Government, the Contractor shall exert its best efforts to: Perform carcinogenesis bioassay feeding tests in mice, rats, or other rodents of pesticides and other environmental chemicals selected by the Project Officer. In performing the above, the Contractor will: 1. Procure chemicals, analyze for amount and types of impurities, determine stability and purify when indicated by the Project Officer. 2. Conduct subacute oral toxicity studies to determine maximum tolerated dose for use in the long-term study. 3. Perform lifetime feeding tests for carcinogenicity studies in groups of 50 mice and 50 rats of each sex at two dose levels. Appropriate positive and negative controls will be used as indicated by the Project Officer. 4. Maintain adequate check of the diet regarding stability of test compound. Observe and record weight gain and health of animals, and acceptance of food. 5. Sacrifice moribund animals and perform complete autopsy on all animals including histologic examination of all indicated target tissues as well as tumors at other sites. 6. Record data on forms provided by the National Cancer Institute. Results will be evaluated for significance.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.0625, REMOVAL OF PESTICIDE RESIDUES IN DAIRY PRODUCTS

J.H. GHOLSON, Louisiana State University, Agricultural Experiment Sta., *Baton Rouge, Louisiana* 70803 (LAB01206)

OBJECTIVE: Study food and feed products with respect to the location and persitence of pesticide residues in market products, effects of pesticide residues on quality characteristics, and the development of commercial marketing and processing techniques for the detection, removal and/or neutralization of pesticide residue effects.

APPROACH: Milks containing insecticides (e.g., DDT, lindane, methoxychlor and endrin) will be subjected to normal milk plant pocesses such as pasteurization, fat separatiion, condensing, cultured milk products and cheese manufacture. The milk will be analyzed before treatment, after treatment, and after various storage times for the residues.

PROGRESS: Previous work on vacuum concentration of milk containing insecticides resulted in a reduction of insecticide levels as follows: 16-86% for DDT, 23-65% for endrin and 36-100% for lindane. Subsequent work has been on similarly 'spiked' milk concentrated in a 36 inch Rogers vacuum pan at reduced pressures varying from 574 to 698 mm Hg. Various combinations of DDT, endrin and lindane were used in four trials. Reduction in the insecticide levels in the milk after concentration as compared to the unconcentrated were as follows: 2-23% for DDT, 15-32% for endrin and 41-50% for lindane. The remainder of the study on this project (SM-32), which is scheduled to be terminated June 1969, will include work on improved distillate traps to attempt to recover that portion of the insecticide which is removed by reduced pressure distillation. This will be necessary to determine whether the insecticides are truly going over into the distillate or disappearing in some other manner such as break-down products which are not recoverable in the procedure used.

SUPPORTED BY U.S. Dept. of Agriculture

4.0626, REMOVAL, IN MARKET CHANNELS, OF INSECTICIDE RESIDUES FROM MILK AND MILK PRODUCTS

J.H. GHOLSON, Louisiana State University, Agricultural Experiment Sta., *Baton Rouge, Louisiana* 70803 (LAB01501)

OBJECTIVE: Develop procedures for removal of insecticides in milk. Determine location of insecticide in product with help of model systems. Examine certain microorganisms for possibility of biodegradation of insecticide.

APPROACH: Cream separation followed by washing and churning will be utilized to determine whether the insecticide is oriented to the surface or to the interior of the fat globule. Additional procedures involving severe agitation of milk, which moves fat globule surface material to the serum phase will be used to further ascertain insecticide location. Model systems will be developed to study various chemical and physical procedures for finding, removal or reduction of specific insecticides. Certain microorganisms will be grown in simple medias to determine relationship between the microorganism and the specific insecticides.

Standard FDA procedures for sample 'clean-up' and electron-capture analysis will be used on all samples.

PROGRESS: A preceding project La. 1206 was terminated June 1969. This project was initiated at that time. Work to date has shown significant reductions in levels of lindane in milk, when subjected to metabolic activity of B. cereus, E. coli and S. lactis of 45, 42, and 39%, respectively.

SUPPORTED BY U.S. Dept. of Agriculture

4.0627, TOXICANTS AND BAITS FOR CONTROLLING NUTRIA IN AGRICULTURAL AREAS

F. SCHITOSKEY, U.S. Dept. of the Interior, Nutria Research Station, *Houma, Louisiana* 70360

Objective: To continue evaluating and improving existing methods and materials for controlling nutria damage, and to develop and evaluate new methods and techniques that show potential for controlling nutria damage.

Procedures: Promising materials, including oral and contact poisons, gases or inhalants, and systemic poisons, will be tested on caged nutria. All materials which appear promising for nutria control will be bioassayed on other animals likely to be endangered. Field tests will include improved bait presentation for extensive area control, testing promising materials in the field, and testing and devising techniques for treating dens and vegetative home sites. Emphasis will be toward testing and developing new techniques for controlling nutria.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0628, TOXICOLOGICAL STUDIES WITH JAPANESE QUAIL

T.E. SHELLENBERGER, Gulf South Research Institute, *New Iberia, Louisiana* 70560

The objectives of this program are to compare toxicity responses of Japanese quail and other wildlife to various chlorinated hydrocarbon and organophosphate pesticides, determine interactions of multiple pesticide exposures in Japanese quail, and evaluate effects of pesticides on reproductive capacity of penned and laboratory housed quail. Results of these studies will provide important information (1) on the effects of pesticides to wildlife, (2) on the utility of Japanese quail as a laboratory tool to evaluate hazards of new chemicals, and (3) provide a basis for comparing laboratory and field toxicity studies on the effects of established chemicals ultimately to improve protocols for evaluating effects of new pesticides.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.0629, EFFECT OF PESTICIDES ON ENZYME SYSTEMS

G.G. GUILBAULT, Louisiana State University, School of Science, *New Orleans, Louisiana* 70122

We are studying the effect of various classes of pesticides: insecticides (chlorinated, carbamate and organophosphorus), herbicides and fungicides on various enzymes of all types: esterases (cholinesterase, chymotrypsin, hyaluronidase, phosphatase, sulfatase, lipase, glucosidase, glucuronidase, etc.), oxidases, hydrogenases, anhydrases, kinases and transferases. In addition attention is being paid to other sources of cholinesterase: eel and insect (beetle, roach, etc.).

Attempts are being made to develop sensitive and specific analytical procedures for important insecticides, herbicides and fungicides using ultra sensitive fluorometric procedures.

The effect of pesticides on cholinesterases from insects (cockroaches, fire ants, housefly), from human serum, rat liver, electric eel, bean leaf beetle and white fringe beetle and from bacteria has been studied. The enzyme hexokinase was measured for its sensitivity to pesticides -- only 4 chlorinated pesticides (Aldrin, chlorodane, DDT and heptachlor) were found to affect this enzyme.

Two new enzymes were isolated -- rhodanase and injectase. These enzymes were found to be able to decontaminate water by removal of cyanide. New fluorometric methods were developed for the assay of these enzymes.

4.0630, EFFECTS OF DDT

R.B. ANDERSON, State Dept. of In. Fish & Game, *Augusta, Maine* 04330

Objectives: To monitor the increase or decrease in the DDT,DDD,DDE, Dieldrin, and Endrin content of annual samples of salmon from Sebago Lake.

Procedure: A sample of 30 male age III plus salmon will be collected from the fall spawning migration in the Jordan River. The sample will be divided into two sub-samples, one sub-sample will be 15 poor condition fish and the other will be 15 good condition fish. Good and poor condition will be chosen by visual examination.

All salmon will be analyzed individually and the total insecticide content will be determined for each fish. Insecticide content will be determined on a wet weight basis. The fat content of each sample will be determined.

Insecticide analysis data will be compassed with data collected in previous years.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0631, THE EFFECTS OF DDT AND OTHER PESTICIDES ON SEBAGO LAKE SALMON

S.E. DEROCHE, State Dept. of In. Fish & Game, *Augusta, Maine* 04330

Objectives: To monitor the increase or decrease in the DDT, DDD, DDE, Dieldrin, Endrin, and BHC content of Sebago Lake salmon.

Procedures: Every other year, beginning in 1971, a sample of 30 male, age III plus salmon will be collected from the fall spawning migrations in the Jordan River. Ten salmon from this group will be analyzed individually to determine the variance that may exist within age group III plus salmon. A composite of all 30 salmon will be analyzed to determine the amount of pesticides in the total sample of age III plus salmon. Insecticide levels will be determined on wet weight basis. The fat content of each sample will be determined.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0632, ECOLOGY OF ANIMALS IN DDT-CONTAMINATED ENVIRONMENTS

J.B. DIMOND, Univ. of Maine, School of Forestry, *Orono, Maine* 04473

A large, forested area of northern Maine has been sprayed serially with DDT at 1 lb/acre for control of the spruce budworm; control projects were carried out in 1958, '60, '61, '63, '64 and 1967. While there was considerable overlap in the different projects, sizable areas remain that were treated only once but in the years indicated above. There are also large blocks which have received two or three treatments and surrounding, ecologically similar areas which have no recorded spray history. The resulting mosaic of forest areas with varying histories of DDT-treatment appears to present a unique opportunity to study persistence and movement of DDT in the forest ecosystem. Such studies have been in progress for three years at Maine university and have demonstrate extreme persistence, beyond ten years, of low levels of DDT in several types of animals following even a single application of the chemical. These highly persistent residues are apparently below lethal levels at least for the forms studied, but the possibility remains that some damage results to the animal populations involved. This proposed research would attempt to determine whether individals and populations of selected animals are affected in any detectable way by continued contamination with sublethal quantities of DDT. It is proposed that the problem be approached primarily by studying the population dynamics of the selected animals in natural environments contaminated with varying levels of this insecticide. Most of the existing work on chronic effects of sublethal residue levels of DDT has involved laboratory studies. While the results have been interesting, it has been very difficult to evaluate the significance of these effects in nature. Only field studies can provide the answer.

4. PESTICIDES

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.0633, IMPACT OF PESTICIDES UPON SEMI-WILD ECOSYSTEMS
J.B. DIMOND, Univ. of Maine, Agricultural Experiment Sta., *Orono, Maine* 04473 (ME00202)

OBJECTIVE: Continue studies of the ecological significance of long-lasting DDT residues to contaminated forest animals; monitor the effects on the forest ecosystem of fenitrothion applied for control of the spruce budworm.

APPROACH: As a result of DDT applications for spruce budworm control in several previous years, areas can be found with widely ranging levels of long-lasting DDT contamination in soils and several organisms. Population success of animal species in heavily contaminated areas will be compared to lightly contaminated areas. Special attention will be paid to reproductive effects. Fenitrothion has replaced DDT as the recommended chemical for spruce budworm control. Little is known of the environmental impact of this new chemical. Several phases will be studied including effect on aquatic insect populations, on parasites of the budworm, and the effectiveness of the chemical itself in controlling the target insect.

PROGRESS: Emphasis continued on the determinations of levels of DDT and metabolites remaining in various components of the forest ecosystem up to 10 years following 1 to 3 applications. Monitoring of soils, some plants and many animals is complete for the terrestrial environment. Residue determination in aquatic communities is nearly complete. Residues are seen to persist through 10 years, with some decline, in most animal species and in soils. There is abundant evidence of food chain magnification and of residue build up with successive applications of DDT. A series of 300 brook trout were taken from 50 streams having varying spray histories. The fish can be expected to cover a broad range of residue contamination. We will attempt to correllate differences in growth or anatomical parameters with residue level.

SUPPORTED BY U.S. Dept. of Agriculture

4.0634, TISSUE STRUCTURE AND GROWTH OF RATS FED LARD CONTAINING INSECTICIDES
M. ADAMS, U.S. Dept. of Agriculture, Human Nutrition Research Div., *Beltsville, Maryland* 20705 (HN2-49A)

OBJECTIVE: Determine the influence of feeding lard from hogs that had been fed diets containing DDT, malathion and methoxychlor.

APPROACH: Determine the insecticide present in the tissues of rats fed from weaning diets identical in all respects except for the lard from hogs fed diets containing different kinds and levels of insecticides. Analyses will be carried out on tissues from rats one year old. Analyses will be done on younger animals if the results with the older animals suggest the need. Evaluate results in cooperation with the staff of Columbia University under Cooperative Agreement - HN 2-49(CA).

PROGRESS: See Accession Number 0015580.

SUPPORTED BY U.S. Dept. of Agriculture

4.0635, PHYSIOLOGICAL RESPONSE TO DIETS WITH DIFFERENT FATS AND INSECTICIDES
M. ADAMS, U.S. Dept. of Agriculture, Human Nutrition Research Div., *Beltsville, Maryland* 20705 (HN2-43)

OBJECTIVE: Determine influence of diets containing different fats with low levels of insecticides on fatty acid and insecticide content of tissues of parents and of three successive generations.

APPROACH: From weaning, feed male and female rats diets containing soybean oil, cottonseed oil, lard or hydrogenated vegetable oil with or without chlorinated hydrocarbons. In addition feed diets containing heated cottonseed oil and lard. As insecticides, provide a mixture of chlorinated hydrocarbons (DDT, lindane or methoxychlor) at levels within acceptable limits. Determine fatty acid content of adipose tissues of animals from each diet group and for each generation. Analyze selected tissues for insecticide content.

PROGRESS: See Accession Number 0015576.

SUPPORTED BY U.S. Dept. of Agriculture

4.0636, EFFECTS OF DDT AND ANALOGUES ON REPRODUCTION IN DOMESTIC MAMMALS AND BIRDS
J. BITMAN, U.S. Dept. of Agriculture, Hormone Physiology Laboratory, *Beltsville, Maryland* 20705 (039801421321)

OBJECTIVE: Determine the effects of DDT on reproductive functions of domestic mammals and birds.

APPROACH: The estrogenic activity of o,p'-DDT and its influences upon reproduction will be determined when it is incorporated at low levels in the diet of rats, sheep and poultry. Reproductive tissues will be studied to determine pesticide residues and changes in biochemical composition. Reproductive parameters such as fertility, pregnancy, hatchability, and survival of young will be assessed. Egg production will also be studied in poultry.

PROGRESS: Japanese quail fed p,p'-DDT or o,p'-DDT in a 0.6% Ca diet produced smaller eggs with thinner shells than controls. With 1% Ca, DDT had no effect on egg shell quality. DDT delayed the first ovulation of birds on low (0.6%) or high (2.5%) Ca diets. Carbonic anhydrase activity of shell forming glands of birds fed DDT or DDE was 16 to 18% lower than of quail on a diet free of pesticides. Levels from 5 to 50 ppm o,p'-DDT p,p'-DDT and p,p'-DDE in the diet (2.5% Ca) of leghorn chickens for 7 months had no effect on body gain, egg production, eggshell thickness or calcium, fertility, hatchability or survival of progeny. Uteri from rats, voles, chicken or quail injected with o,p'-DDT showed increases in weight, water content, glycogen and RNA indicating that the o,p'-isomer is estrogenic in these species. 10,000 mug o,p'-DDT was equivalent to 1 mug estradiol. P,p-DDT produced little response. Sheep fed 10 ppm o,p'-DDT in their diet, during the mating season had normal uterine biochemistry, estrous cycles, reproduction and lactation. The condition of the lambs was unaffected. Compounds related to DDT were screened for estrogenic activity. Diphenylmethane, diphenylethane and triphenylmethane compounds were estrogenically active when a p- or p'-position was unoccupied or occupied by a hydroxyl or methoxy group. Halide or alkyl groups in the p,p' positions rendered the compounds inactive. In the rat, DDT, DDE and DDD, stimulated liver destruction of barbiturates so that the rats had a shortened pentobarbital sleeping time. In birds, the opposite effect occurred and DDT, DDE, DDD, methoxychlor and malathion prolonged sleeping time.

SUPPORTED BY U.S. Dept. of Agriculture

4.0637, TISSUE RESIDUE ACCUMULATION AND PHYSIOLOGICAL AND REPRODUCTIVE RESPONSE OF LINDANE-TREATED SWINE
R.J. DAVEY, U.S. Dept. of Agriculture, Animal Science Research Div., *Beltsville, Maryland* 20705 (033204070121)

OBJECTIVE: Determine the rate of accumulation of lindane residues in tissues of swine and the associated effects on blood constituents and reproductive performance.

APPROACH: Thirty-two males and 24 females will be assigned to a control and three treatment groups: lindane sprayed, 0.05% solution; lindane fed, 2 mg/kg body wt/day; and lindane fed, 20 mg/kg body wt/day. Treatment will begin at 3 months of age and samples (blood and backfat biopsy) will be taken at 6-week intervals. Six of the males will be sacrificed at 6 months of age and the remaining will be withdrawn from treatment. Females will be continued on treatment, bred at 10 months of age, and sacrificed after farrowing. Blood and backfat samples will continue to be taken from the remaining males and the females until slaughter. Tissue samples taken at slaughter and biopsy will be analyzed for lindane residues. Plasma amino acids and some other biochemical components of blood will be analyzed to determine the effect of treatment.

PROGRESS: A preliminary experiment was conducted in which 40 mg. of lindane/kg. of body weight per day was established as maximum daily intake. The actual experiment was initiated using a 0.05% lindane solution sprayed on the feed to provide dietary treatments of 0, 2, and 40 mg./kg. body weight

per day. The first half of the experiment has been completed. The majority of the experimental material collected has not yet been analyzed.

SUPPORTED BY U.S. Dept. of Agriculture

4.0638, INSECTICIDE RESIDUES IN TISSUES AND MILK OF DAIRY COWS

G.F. FRIES, U.S. Dept. of Agriculture, Animal Science Research Div., *Beltsville, Maryland* 20705 (033102970121)

OBJECTIVE: Determine factors affecting insecticide absorption, retention and excretion by dairy cattle.

APPROACH: The conversions and losses of insecticides on forages will be studied to determine how they may be affected by environmental conditions and processing. Studies will be conducted on rats as well as cows to determine what drugs and nutritional or management regimes will reduce insecticide absorption and/or increase the rate of clearance from body fat. The relationship between changes in body energy and insecticide levels in milk and flesh will also be studied.

PROGRESS: Two experiments were conducted to determine the effectiveness of activated carbon in reducing body stores of pesticides from cows. In a 14-day experiment, 1 kg/day activated carbon had no effect on the milk concentrations of dieldrin, DDD or p,p'-DDT. In a 26-day experiment, 1 kg/day activated carbon had no effect on the milk concentrations or the body fat concentrations of dieldrin, DDD or p,p'- DDT. Three experiments were conducted to determine the effect of liver enzyme inducing drugs on the removal of pesticides from cows' body fat. In a 14-day experiment, 5 g/day of sodium pentobarbital had no effect on the milk concentrations of dieldrin, DDD or p,p'-DDT. In a second experiment, 5 g/day of sodium pentobarbital for 14 days and 24 g/day for an additional 14 days had no effect on the milk concentrations or the body fat concentrations of dieldrin, DDD or p,p'-DDT. In a 25-day experiment, sodium phenobarbital approximately doubled the rate of decline of milk concentration of dieldrin and increased the rate of decline of the milk DDE by about 20%. Diphenylhydantion had no effect on either of these pesticides. Experiments with rats indicate that 2.5 ppm o,p'-DDT in the diet exerted no detrimental effect on reproduction and it had no significant effect on the estrogen dependent physiological events which have been effected by o,p'-DDT at higher levels. The eggshell forming glands of Japanese quail fed p,p'-DDT or p,p'-DDE had carbonic anhydrase activity 16 and 19% lower than the shell glands of quail on a diet free of pesticides.

SUPPORTED BY U.S. Dept. of Agriculture

4.0639, LOSS OF BODY FAT AND RESPONSE TO INSECTICIDE RESIDUES

F.L. LAKSHMANAN, U.S. Dept. of Agriculture, Human Nutrition Research Div., *Beltsville, Maryland* 20705 (HN2-44)

OBJECTIVE: Determine whether low levels of chlorinated hydrocarbon insectides produce chemical or structural changes in obese and nonobese rats when maintaining or losing body weight.

APPROACH: Feed male and female rats diets that produce obesity or that do not. Include in the diets of half of the rats levels of chlorinated hydrocarbon insecticdes currently considered safe. Restrict food intake of some rats to induce weight loss. Estimate body composition at intervals. At scheduled periods, kill and note gross abnormalities. Measure serum proteins, cholesterol and fat, liver fat, body composition, and DNA of adipose tissue. Measure oxygen uptake of brain and liver slices as well as response of sciatic nerve.

PROGRESS: In order to determine more specifically the proteins most responsive to diet during growth and development, serum from animals fed the diets without insecticides was subjected to high resolution Disc electrophoresis. Of the twelve protein components normally present in rat serum pre-albumin, transferrin and beta-1 lipoprotein content were affected by diet and/or age. Pre-albumin, a fraction previously shown to be associated with lipid, was affected by level of dietary fat. Content of transferrin, the iron transporting protein of serum, varied with kind of fat in the diet. Regardless of diet beta-1 lipoprotein as well as total lipid content of serum increased with age. Significant variation was observed among these apparently healthy animals. This contributed in part at least to the difficulty in establishing diet differences with a small group of rats examined at 100-day intervals. Feeding the diets with and without insecticides, and K-40 measurements in the live rats have been completed.

SUPPORTED BY U.S. Dept. of Agriculture

4.0640, EFFECT OF MALATHION AND SEVIN ON REPRODUCTIVE PERFORMANCE OF THE HEN

R.J. LILLIE, U.S. Dept. of Agriculture, Animal Science Research Div., *Beltsville, Maryland* 20705 (032911321321)

OBJECTIVE: Determine the effect of long-term feeding of pesticides singly and in combination, on reproductive performance of laying hens and performance of their progeny.

APPROACH: Laying hens will be fed malathion and Sevin singly and in combination at different levels. Egg production, egg weight, fertility and hatchability data will be collected. Unhatched eggs will be examined for embryo malformation. Data on progeny performance to four weeks of age will be collected. Initially, levels of 250 and 500 ppm of malathion alone, of sevin alone, and malathion and sevin in combination will be used in addition to controls. Each of the seven groups will consist of 30 SCWL pullets kept in individual cages and fed a standard breeder diet. Observations will be made on egg production, feed consumption, body weight maintenance, egg weights, fertility, hatchability and subsequent progeny performance. Unhatched eggs will be examined for embryo malformation. If no gross differences or abnormalities are observed in the embryos or progeny as a result of feeding the pesticides to the dams, the levels of pesticides will be determined in the eggs and chicken tissues.

PROGRESS: Malathion and Sevin were fed at levels of 250 and 500 ppm, singly and in combination, to laying hens for 32 weeks. The 500 ppm level of Sevin and the 500 ppm level of the combination of pesticides resulted in a decrease in body weight. There was a slight depression in egg production on the 500 ppm level of the pesticides singly and in combination. There was no effect on egg weight, egg shell thickness, fertility or hatchability. The incidence of malformed embryos was essentially negative, three were found in 2800 incubated eggs. The pesticides had no effect on progeny performance. In studies with DDT op'DDT, pp'DDT and pp'DDE fed singly to laying hens at levels of 5, 25 or 50 ppm for 28 weeks had no adverse effect on body weights, feed efficiency, egg production, fertility, hatchability or progeny performance. When the levels of these compounds were increased for 8 weeks to 150 and 300 ppm in the two groups that had received 5 and 25 ppm, with the 50 ppm group remaining the same, there was no effect on fertility and hatchability.

SUPPORTED BY U.S. Dept. of Agriculture

4.0641, EFFECT OF INSECTICIDES IN FEED ON GROWTH, BODY STORES, AND REPRODUCTION OF SHEEP

I.L. LINDAHL, U.S. Dept. of Agriculture, Animal Science Research Div., *Beltsville, Maryland* 20705 (033302070121)

OBJECTIVE: Determine the effects of certain insecticides on growth and reproduction of sheep and to determine the presence of residues of the insecticide in the milk, muscle, fat and certain body organs.

APPROACH: Groups of 12 ewes and 3 rams will be fed in drylot over a 2 year period the following pelleted alfalfa diets: Zero level of insecticides, 2x the tolerance level for a chlorinated hydrocarbon and an organic phosphate, and 10x the tolerance levels for the 2 types of insecticides. Observations will be made on the reproductive performance including lamb production, semen quality and mating behavior. Growth and development of lambs will be measured. Lambs will be slaughtered at 5 months of age or at wt of 45 kg. Tissues of lambs and older animals plus milk of ewes will be checked for residues. Plan of work to be altered as indicated by results.

PROGRESS: Sixty ewes were divided into 5 groups in November 1968. Group I received insecticide free hay; II hay plus 2 X tolerance limit of parathion; III hay plus 10 X parathion; IV hay plus 2 X gluthion and V hay plus 10 X gluthion. Number of parturitions and lambs born during 2 reproductive seasons were 20 and 29; 17 and 24; 18 and 25; 13 and 17; and 19 and 26,

respectively, for the 5 groups. Number of ewes lost between November 1968 and July 1970 were 1, 2, 2, 4 and 2, respectively. Increase in wool clip per ewe between the 1969 and 1970 seasons (matched ewes) was 0.6; 0.4; 0.3; 0.1 and 0.1 kg., respectively, while changes in body weight were 7.6; 7.1; 7.9; 14.7; and 5.6 kg. It appears that the insecticides fed had at least a slight depressing effect on livability and production.

SUPPORTED BY U.S. Dept. of Agriculture

4.0642, PERFORMANCE OF SWINE FED PESTICIDES AND RESIDUES IN BODY TISSUE

D.P. MORGAN, U.S. Dept. of Agriculture, Animal Science Research Div., *Beltsville, Maryland* 20705 (033201770121)

OBJECTIVE: Determine effects of prolonged ingestion of pesticides on growing-fattening swine and breeding females and measure residue accumulation and diet appearance in body fluids and tissues.

APPROACH: Phase I. Nine groups of barrows and gilts, averaging 81-5 pounds are fed either a control diet, one of three levels of heptachlor, one level of DDT or malathion, heptachlor epoxide in either hay or milk or heptachlor and sprayed with malathion. Blood and backfat samples were obtained at regular intervals for residue analyses. Two metabolism trials were conducted. Four swine per treatment were sacrificed after 98 days for tissue analyses. Two barrows in each lot switched to the control diet had backfat samples taken to determine rate of residue depletion. Phase II. Six gilts in each group except the choice fed lot, were continued on their prescribed diets through three reproductive cycles. Pesticides were not added to the lactation diet. Performance data, milk samples, and tissue from newborn and weanling pigs were collected. Body tissues were collected from two sows in each lot sacrificed after weaning their third litter.

PROGRESS: Blood samples were analyzed for heptachlor epoxide, p,p'-DDT, and malathion. Samples were taken at 2-week intervals from pigs fed these pesticides. Maximum residue in blood of swine fed an alfalfa hay diet containing a total of 28 ppm of heptachlor was about 0.01 ppm heptachlor epoxide. In blood from pigs fed an alfalfa hay diet containing 34 ppm DDT, there was up to 0.56 p,p'-DDT. In blood from pigs fed an alfalfa hay diet containing 150 ppm malathion, no malathion or malaoxon was detected. Final results on tissue residues from these pigs are being assembled and will be submitted in the next report.

SUPPORTED BY U.S. Dept. of Agriculture

4.0643, PESTICIDE RESIDUAL ACCUMULATION AND ELIMINATION BY SWINE

D.P. MORGAN, U.S. Dept. of Agriculture, Animal Science Research Div., *Beltsville, Maryland* 20705 (033201870121)

OBJECTIVE: Determine rate of accumulation and elimination of pesticide residues by swine fed or sprayed with coumaphos, malathion, DDT, or lindane.

APPROACH: Five barrows per replication will be allotted as follows: one control fed pesticide for 14 weeks, one fed pesticide forst 7 weeks, one sprayed biweekly for 14 weeks, and one sprayed biweekly first 7 weeks. Your replications per pesticide. Metabolism trials conducted with three replications during 8th and 14 weeks. Backfat samples collected during 9th 11th and 13th weeks for residue analyses. Animals sacrificed after 14 weeks and body tissues collected for residue analyses. Pesticides used for first year are coumaphos and lindane, second year, malathion and DDT.

PROGRESS: A study of residue levels resulting from spraying or feeding lindane to boars of the high-fat and control lines of the Duroc and Yorkshire breeds contained the following treatments: control, sprayed twice with a 0.5% lindane solution, fed 1 mg of lindane per kg of bodyweight per day, fed 2 mg of lindane. There were only small traces of lindane found in urine (1 ppm) and the fecal levels did not exceed 0.61 ppm. Urinary and fecal lindane levels did not appear to be associated with treatment. Liver residues exceeded 0.1 ppm in only one pig, and although average treatment levels increased with dosage, they were all less than 0.1 ppm. Kidney lindane levels averaged 0.01 ppm in controls, 0.10 ppm in sprayed pigs and 0.33 and 0.66 ppm in those fed 1 and 2 mg, respectively. There was a marked accumulation of lindane residues in backfat and loin lean tissue. Levels in backfat and loin lean, respectively, were 0.19 and 0.05 ppm for controls, 5.15 and 0.57 ppm for sprayed pigs, 19.50 and 2.37 ppm for those fed 1 mg, and 44.25 and 6.55 ppm for those fed 2 mg. Lindane residues in excess of established tolerance levels (4 ppm) can accumulate in edible tissue both by feeding and spraying the compound. However, in this study the sprayed level was about 10 times that recommended in practice.

4.0644, EFFECT OF RUELENE (REG. TRADEMARK) ON EMBRYONIC DEVELOPMENT

T.D. RUMSEY, U.S. Dept. of Agriculture, Animal Science Research Div., *Beltsville, Maryland* 20705 (033005621321)

OBJECTIVE: Determine the amount of 4-tert-butyl-2-chlorophenyl methyl methylphosphoramidate (Ruelene(Reg. trademark)) which reaches the fetus and the teratogenic effects of this systemic pesticide.

APPROACH: The study will involve three phases of experimentation: Following dermal application of Ruelene(Reg. Trademark) to beef cows, blood samples will be analyzed for Ruelene(Reg. Trademark) to estimate the amount of pesticide absorbed into the blood stream; pregnant cows, at 35 days gestation, will be injected with Ruelene(Reg. Trademark) and blood residue patterns will be established both in the cow and the fetus; and pregnant cows, at 35 days gestation, will be injected with Ruelene or saline via the jugular vein or directly into the amnionic sac and 100-day fetuses will be examined for abnormalities.

PROGRESS: No abnormally developed fetuses (150 days gestation) have been obtained from cows after intravenous and intrauterine injections of Ruelene(Reg) at 35 days gestation. Preliminary summarization indicates that the crown to rump length and weight of the 150-day fetuses were not affected by Ruelene(Reg). Two intrauterine injected cows, one given saline and one given Ruelene(Reg) lost their fetus after the injection at 35 days gestation which indicated the critical nature of the experimental treatment. The synthesis of C - labeled Ruelene(Reg) has been completed.

SUPPORTED BY U.S. Dept. of Agriculture

4.0645, METABOLISM OF PESTICIDES BY BEEF CATTLE

T.S. RUMSEY, U.S. Dept. of Agriculture, Animal Science Research Div., *Beltsville, Maryland* 20705 (033001627012 1)

OBJECTIVE: Study site of absorption, distribution of tissue residue, pathways of excretion and chemistry of pesticides in beef cattle for the ultimate protection of the animal and the consumer.

APPROACH: Techniques used to investigate the metabolism of pesticides by beef cattle will include cannulation of the portal and ruminal veins to estimate rate of blood flow and pesticide absorption; quantitative collections of feces, urine and respiratory gases; location and concentrations of residues in fat, muscle, blood and milk; and measurements of the general physiological status of animals being exposed to pesticides now in use or about to be used.

PROGRESS: The distribution of total DDT residues in beef cattle at concentrations below 5.0 ppm was found to be similar to the distribution at concentrations of 200 to 300 ppm. Kelthane was accumulated less in the fat depots. Urea and energy level did not affect the distribution of DDT and kelthane residues in cattle. Dieldrin accumulated to comparable levels in the caudal and ruffle fat depots of heifers fed aldrin. Cattle infused with KCl and citric acid showed depressed saliva flow, increased heart and respiratory rates and marked changes in EKG patterns. Cattle adapted to a rapid infusion and diet affected post- ingestion changes. Twenty-two pesticides were tested for their toxicity to rumen bacteria in the presence and absence of rumen fluid in the growth media. The toxicity by the pesticide was reduced among those which caused bacterial growth inhibition as the concentration of rumen fluid in the media increased from 0 to 1 to 10 to 30%. Isopropyl N (3 chlorophenyl) carbamate isopropyl N 3 chlorophenyl carbamate, Stam F34 and A minotriazole at 500 ppm were toxic to the three strains of bacteria tested. None of the nitrogen containing pesticides allowed growth of the bacteria

tested if the other nitrogen substrates were deleted from the media. Nor did any of the 22 pesticides serve as a carbon source for growth of the bacteria tested.

4.0646, EXPANDING REPORT ON EFFECTS OF PESTICIDES
UNKNOWN, Litton Industries Incorporated, *Bethesda, Maryland* 20014 (NIH-71-2258)

Independently and not as an agent of the Government, the Contractor will prepare and furnish a revised final report on 'Carcinogenic, Teratogenic and Toxic Effects of Pesticides.' The revised report will be presented in a form which includes additional histology data, additional information about the chemical structures of agents screened, a revised format for the grouping of tested compounds in the tables, and additional information in support of the teratology portion of the report.

The revised report will consist of the following five volumes: Volume I - Revised original data on screening. Volume II - Additional backup histology data. Volume III - Revised original data on teratology and additional backup information. Volume IV - Original data on microbial genetics. Volume V - Additional data on chemical structures and use.

4.0647, CONSULTING IN APPLIED MATHEMATICS AND STATISTICS
J.J. GART, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Natl. Insts. of Health, *Bethesda, Maryland* 20014

To provide consulting assistance and collaboration to NCI scientists on the applications of mathematical statistics and applied mathematics to the planning, interpretation, and analysis of scientific experiments. Assumes an essential role in much research within the NCI, activities include not only statistical analysis but also planning valid experiments. Members of the section will be collaborating on projects in cell transformation by chemical carcinogens, the immunology of Burkitt's lymphoma and the screening of pesticides for possible carcinogenesis.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.0648, ABSORPTION AND EXCRETION OF HEPTACHLOR EPOXIDE BY DAIRY CATTLE
R.F. DAVIS, Univ. of Maryland, Agricultural Experiment Sta., *College Park, Maryland* (033102870121)

OBJECTIVE: Study management and feeding practices in relation to absorption of heptachlor epoxide and its excretion in milk.

APPROACH: Cows will be fed alfalfa hay contaminated with heptachlor residue. During the feeding, additions of mineral oil, commercial animal fats, commercial vegetable fats, calcium lactate, calcium propionate and bentonite will be made to determine their effect on absorption of the residues as determined by biopsy fat samples. The excretion of the insecticide in milk as affected by feeding iodinated casein, different levels of energy intake and partial starvation will be determined. The effect of feeding contaminated hay to heifers on the subsequent excretion of insecticide into milk will be determined.

PROGRESS: The Research Contract under which this work was conducted has been completed. It was concluded that milk excretion is the major pathway for eliminating the body stores of heptachlor epoxide from dairy cows. Dietary treatments such as feeding iodinated casein and various levels and patterns of energy altered the heptachlor epoxide excretion pattern only insofar as milk excretion pattern was altered. Rate of absorption of the insecticide from feed was not appreciably altered by feeding vegetable fat, animal fat, calcium propionate, calcium lactate, mineral oil or bentonite. A high correlation between heptachlor levels in milk and body fat was established and placental transfer of the material was observed. Thus, an animal may contain measurable heptachlor epoxide although no direct consumption has occurred. The information gained is of value to regulatory officials and will be helpful in avoiding future residue problems.

SUPPORTED BY U.S. Dept. of Agriculture

4.0649, METABOLISM OF PESTICIDES IN CATTLE
R.L. KING, Univ. of Maryland, Agricultural Experiment Sta., *College Park, Maryland* (MD-G-055)

OBJECTIVE: Determine the chemical and physical mechanisms involved in the movement of chlorinated hydrocarbons in dairy animals. Identify substances which will inhibit the absorption of residue chemicals and accelerate their rate of excretion from body tissue.

APPROACH: Separate and identify various lipid components from body tissue, blood, feces, urine, and milk with respect to their association with chlorinated hydrocarbons. Suitable radioactive tracers may be employed in these studies. Evaluate poorly absorbed feed additives that may exhibit specific association with pesticide chemicals. Evaluate certain hormone and drug-type chemicals for their ability to influence the excretion of pesticide chemicals.

PROGRESS: The absorption of tocopheryl acetate from the dairy ration by the lactating dairy cow is relatively inefficient as compared to chlorinated hydrocarbon insecticides. When tocopherol was incorporated with various emulsifying agents its direct addition to milk was markedly influenced as measured by its distribution in milk. A study was conducted to determine if similar pre-emulsification of tocopheryl acetate would enhance its absorption from the digestive system of the lactating cow. Several emulsifying agents acceptable as food additives were evaluated in a model system. Tween-20 was selected and used as the vehicle for daily supplementation of four Holstein cows in a changeover type design which included semi-balance studies. The results when inconclusive due to large individual differences, but suggested that emulsification with Tween-20 did not influence excretion of Vitamin E into feces nor the transfer of Vitamin E to milk. Since the latter is so inefficient, additional studies are probably warranted.

SUPPORTED BY U.S. Dept. of Agriculture

4.0650, OXIDATIVE DEALKYLATION OF INSECTICIDES
R.E. MENZER, Univ. of Maryland, School of Agriculture, *College Park, Maryland* 20742

Characterization of the unknown metabolites of C-2307/(CH3O)sub2 P(O)OC (CH3) equals CHC(O)N(CH3)OCH3/ will be accomplished and the complete oxidative route of metabolism will be formulated. Once this is done, we will pursue the question of why the insertion of an oxygen atom between the nitrogen and the carbon in the amide moiety causes such a marked increase in the toxicity of the compound to both mammals and insects over that of dicrotophos. This may lead to a further study of the effect of methylene dioxyphenyl synergists on the metabolism of substituted amide organophosphorus insecticides of this type. It is also planned that the studies relating the metabolism of these compounds to their potentiation or antagonism by liver enzyme inducing agents will be continued. A comparison will be made of the effect of the inducing agents and the increased metabolism of the compounds on the blood A- and B-esterases. With these data it should be possible to draw conclusions about the mechanisms for these effects. We will also utilize the primary human embryonic lung cell cultures to investigate the metabolism of the organophosphates.

4.0651, NUTRITIVE CONTENT OF TYPE A SCHOOL LUNCHES
E.W. MURPHY, U.S. Dept. of Agriculture, Consumer & Food Ec. Res. Div., *Hyattsville, Maryland* 20 '82 (CFE2-14)

OBJECTIVE: Analyze Type A school lunches for selected nutrients and energy value and determine differences in composition related to geographic region and other factors.

APPROACH: With help of Consumer and Marketing Service and State School Lunch Agencies, collect four 6th grade lunches a day for five days at 300 schools representing five geographic re-

gions. Package, freeze and ship to laboratory. Analyze the 300 20-lunch composites for proximate composition, selected minerals, vitamins, fatty acids snd pesticide residues. Calculate average levels of nutrients, energy values, and pesticide residue content for the U.S. and each geographic region. Provide nutritional evaluation of current standards for type A lunch to Consumer and Marketing Service Managers of School Lunch Program. Publish report of study.

PROGRESS: The average Type A lunch contained 31.8 g. fat, which provided 39% of calories and 28.6 g. fatty acids. Fatty acids included 14.6 saturated, 10.2 g. mono-unsaturated, and 3.8 g. polyunsaturated fatty acids. P/S ratio averaged 0.27. Five fatty acids, myristic (C 14), palmitic (C 16), stearic (C 18), oleic (C 18:1), and linoleic (C 18:2), accounted for about 90% of total fatty acids. Linoleic acid about 10% of total fatty acids and 4% of calories. No lunch samples had less than 1% of calories from linoleic acid, but about 1/3 of schools had lunches with less than 3%. Linoleic acid was related to total fat content, to calories, and to % calories from fat, but not to fat-soluble vitamins A or D. Total sterols including but not exclusively cholesterol averaged 112 mg. per lunch with range of 16 to 331 mg. Lunches exceeded 160 mg. sterols for only 6% of schools. Evaluation of data for mineral element content of lunches is currently being made.

4.0652, STUDIES IN CHEMICAL METHODOLOGY FOR DETERMINATION OF PESTICIDE RESIDUES

R.M. PROUTY, U.S. Dept. of the Interior, Bureau of Sport Fish. & Wlfe., *Laurel, Maryland* 20810

Objective: To compare pesticide recovery from tissues by different methods.

Procedures: Preservation methods to be compared include: freezing at 0 degree F., - 70 degrees F., storage at room temperature in formalin, 70 percent ethanol, 95 percent ethanol, dry Na2SO4, or as extracted lipids. Duration of storage will be nine months. Pesticides include DDT, dieldrin, and a DDT metabolite, 4,4'-dichlorobenzophenone. Mallard ducks will be fed a diet containing these compounds to provide tissues for this study.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0653, THE EFFECTS OF PESTICIDE RESIDUES ON LARVAL AND JUVENILE WINTER FLOUNDER IN THE WEWEANTIC RIVER ESTUARY, MASSACHUSETTS

C.F. COLE, Univ. of Massachusetts, School of Agriculture, *Amherst, Massachusetts* 01002

Saltmarshes and their meandering estuarine streams too often have been considered a biological wasteland and public apathy has allowed these areas to become targets of developers of waterfront properties and uncontrolled use of pesticides. The estuarine environment is breeding ground for commercial and sport fishes and little data are available concerning the influence of pesticides upon their general life history. A program was recently established to obtain detailed data on the interaction of pesticides in the estuarine area of the Weweantic River on the northwestern shore of Buzzards Bay. The pesticide investigation will study the possibility of acute toxic conditions occurring from single instances of pesticide application. As the occurrence of parathion in the estuary is ephemeral at most, and, as parathion is one of the major insecticides now used on cranberry bogs, this study is of major significance. The objectives of this project are to study the larval blackback flounder mortality under controlled laboratory conditions; to study a comparative larval mortality in three widely separated geographical areas; to conduct bioassay studies which will delimit tolerance levels, especially for blackback larval flounder; and to conduct a more critical study of the occurrence of area specificity, as evidenced in previous chromatographic patterns.

4.0654, PESTICIDE RESIDUE EFFECTS ON LARVAL MARINE FISHES

C.F. COLE, Univ. of Massachusetts, School of Agriculture, *Amherst, Massachusetts* 01002

Effects of chronic, low-level pesticide exposures on eggs and larvae of the winter flounder (Pseudopleuronectes americanus, Walbaum) are being evaluated. A previous segment of this project examined chlorinated hydrocarbon residue levels in winter flounder from the Weweantic River estuary, a small tidal tributary of Buzzards Bay, Massachusetts. The effects of these residue levels on the reproductive success of the flounder using this estuary as spawning and nursery grounds is of particular concern. Field investigations have demonstrated that certain insecticides (DDT and dieldrin) commonly used in the watershed by cranberry culturing and mosquito control programs are present in the flounder; heptachlor is also present but its source is unknown. Increasing concentrations of these insecticides were noted in flounder ovaries during the months prior to spawning. Laboratory investigations are presently underway to determine what concentration ranges of the insecticides residues in gonadal tissues generate measurably adverse effects during reproduction. The survival of eggs, larvae, and juveniles spawned from dosed adults is being followed and the reproductive success is then to be evaluated in light of concentrations from gonads of similarly treated adults. Gas-liquid chromatography is the major analytical tool. The flounder dosing and rearing experiments are being undertaken at the Bureau of Sport Fish and Wildlife Laboraory, Narragansett, Rhode Island.

4.0655, EXPERIMENTAL OPTIC NEUROPATHIES

S. LESSELL, Boston University, School of Medicine, *Boston, Massachusetts* 02215

Having completed pilot studies of the effect of chronic cyanide intoxication upon the anterior visual apparatus of the albino rat, I will proceed to further define the characteristics of the neuropathy. This work will be largely histochemical and will seek to identify the earliest histochemical alterations in cyanide intoxication. Following chronic cyanide administration (by intraperitoneal route), the animals will be serially sacrificed and fresh cryostat sections incubated for the demonstration of succinic and lactic dehydroginase alkaline and acid phosphatase, ATPase and cytochrome oxidase. The corpus callosum will also be studied. An attempt will be made to modify the effects of cyanide intoxication by the concurrent administration of high doses of hydroxycobalomin, a compound which is known to have an enormous affinity for cyanide. It has been suggested that in human optic nerve disorders, thought to be consequent to chronic cyanide intoxication, hydroxycobalomin might be of therapeutic benefit.

In addition to the above studies, pilot experiments into the effect

$ of chronic lead intoxication on the visual apparatus will be initiated. Lead will be administered in drinking water and the peripheral and central nervous system will be examined in collaboration with the Department of Neurology.

4.0656, FACTORS AFFECTING PESTICIDE TOXICITY

S.D. MURPHY, Harvard University, School of Public Health, *Boston, Massachusetts* 02115

The long term goal of the proposed research is to contribute to the understanding of relationships between metabolism and toxicity of pesticides. Major emphasis will be placed on studies of species comparisons of metabolic and toxic interactions of organophosphorus insecticides with other chemicals and drugs. Species to be studied include members of 4 classes of vertebrates; mammals, birds, fish and amphibians. Chemicals which inhibit tissue hydrolases or which induce or inhibit microsomal enzymes that are involved in the metabolism of phosphorothioates will be studied to obtain time and dose response relationships for both effects on metabolism and effects on toxic interactions in intact animals. A search for a possible physiologic significance for the potent carboxylesterase inhibiting properties of some phosphate insecticides will be made. Newer insecticides which have relatively low acute toxicity will be studied to determine their potential to produce subtle effects that are unrelated to the well known anticholinesterase action of orgnophosphates. It is felt that this research will contribute to the understanding and predictability of

adverse effects of pesticides in man and other desirable species. An indirect, but important objective will be to provide a stimulating research program as a base from which graduate students can develop thesis research projects.

4.0657, BIOCHEMICAL AND PHYSIOLOGIC RESPONSE TO TOXIC STRESS
S.D. MURPHY, Harvard University, School of Public Health, *Boston, Massachusetts* 02115

The broad objectives of this project are to increase understanding of how various industrial chemicals and environmental contaminants affect neural, endocrine, and enzymatic regulatory mechanism. Research has been concerned with the effects of acute exposures to toxic irritant chemicals, organophosphate and organochlorine insecticides, and hepatotoxic chlorinated hydrocarbons on regulatory mechanisms of the pituitary-adrenocortical axis in rats. Relationships between endocrine changes induced by these chemicals and the activities of glucocorticoid- inducible and other liver enzymes have been studied. Interactions of the effects of toxic chemicals with physical stresses and with natural circadian variations which affect adrenocortical function have been studied. Recent research has concerned development methods of evaluating chronic peripheral neuropathy in intact animals that can be used as a clinical correlate to biochemical and histologic changes caused by the neurotoxic chemical acrylamide. Investigation of the similarities and differences of the biochemical effects of carbon tetrachloride and chlorinated ethylenes are in progress. Emphasis will be placed on studies of the mechanisms by which drugs or environmental stress alter the response to these hepatoxic chemicals. These studies provide basic information which may be useful in predicting the capacity of man and other animals to adapt to various stressful stimuli and in anticipating hazardous combinations of toxic chemicals, drugs, and stresses.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.0658, OCCUPATIONAL AND ENVIRONMENTAL HEALTH
J.L. WITTENBERGER, Harvard University, School of Public Health, *Boston, Massachusetts* 02115

This research and research training program includes a variety of approaches to the study of the effects of environmental factors on the health of man. Specific examples include the following: metabolism of pesticides in a variety of animal species, toxic effects of combinations of chemical and physical stresses, experimental pulmonary carcinogenesis in response to combinations of particles and known carcinogens; development of methods for testing of mutagens in mammals; physiology and biochemistry of alveolar macrophages and pulmonary clearance. Epidemiologic studies include study of etiologic factors in chronic nonspecific or specific respiratory diseases (occupational, residential and personal smoking exposure), occupational factors in bladder cancer incidence, and evaluation of the risk of childhood cancer from prenatal exposure to radiation.

Other studies involve the development of improved methods for measuring respiratory exposure to atmospheric contaminants and use of systems analysis approaches to managment of environmental problems.

4.0659, SUBLIMINAL PHARMACOLOGY AND CARCINOGENESIS
L. FRIEDMAN, Mass. Inst. of Technology, School of Science, *Cambridge, Massachusetts* 02139

The activities of this research program are concerned with the basic problems of acquiring knowledge of the effects of chemicals on living organisms, particularly the subtle long range effects that may accompany chronic exposure of men and animals. The ultimate aim is the development of procedures which will facilitate evaluation of potential hazard, particularly the hazards of chemical carcinogenesis presented by the entry additives and contaminants into food, and of pollutants into air and water. A major approach is based on the assumption that observed pathological changes result from interference with normal functions of either the metabolic machinery, the various cellular membranes, or the regulatory mechanism that control cell and tissue metabolism and differentiation. Attempts are being made to adapt and refine biochemical and physiological methods to measure changes in function that will be predictive of cell and tissue damage. Compounds with known biological activity are being studied to establish correlation with new approaches being developed. Specific projects include studies of the metabolic machinery of the cell; studies of a model membrane system; studies of adrenal cortical function; transplantation studies after initiation of carcinogenesis; studies of composition of tumor vs. normal tissues; studies of properties of cell surfaces in normal tissues and tumors; nucleic acid metabolism during carcinogenesis; comparative in vitro cytotoxicity of animal and human cells.

4.0662, FIELD STUDIES OF PESTICIDE EFFECTS ON FISHES
M.E. BENDER, Univ. of Michigan, School of Public Health, *Ann Arbor, Michigan* 48104

The objective of this project is to establish acceptable exposure levels of methoxychlor for fish and other aquatic organisms. This objective will be reached by determining the effect of long-term exposure to sub-lethal levels of methoxychlor by laboratory bioassays and in natural stream conditions. Effect on fish growth will be established in the laboratory with bioassays on two species of fish. Effects on fecundity, survival and production of fish populations and production of benthic organisms will be established from studies in controlled stream environments.

Field studies will be conducted at the Michigan Department of Natural Resources, research station in Saline, Michigan.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

4.0663, FUR ANIMAL NUTRITION STUDIES
R.J. AULERICH, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00117)

OBJECTIVE: Devise rations that will use maximum amounts of dry ingredients; determine value of antioxidants; ascertain calcium and phosphorus requirements with respect to fat levels.

APPROACH: Research is underway to develop dry diets for mink. This will bring in many feed ingredients not presently used in the typical ranch ration. New chemicals are being applied to mink husbandry -- antibiotics and stilbestrol are being studied to determine their value or limitations in mink feeding. It is hoped

that basic nutrient requirements can be studied. Presently vitamin K requirements are being evaluated.

PROGRESS: Experimental diets containing presscake (P.C.) made from either alewife, sucker, smelt, bullhead or carp were fed to mink and results compared with control rations containing either raw, cooked or P.C. ocean perch. Growth on the P.C. diets was comparable with that obtained on the control rations. Reproduction was superior on the raw ocean perch diet. None of the females fed alewife P.C. whelped. Field reports during 1968 indicated that mortality of mink kits whelped by females fed diets containing coho salmon was extremely high. To study this problem, mink and rat feeding trials involving coho salmon have been initiated. The effects of feeding DDT, TDE, DDE and dieldrin on mink growth, livability, fur quality and reproduction were studied. Organ histopathology, tissue pesticide residues, lethal dosage and mink milk pesticide residue contamination are also being investigated. Levels up to 100 ppm of DDT, TDE and DDE had no detrimental effects on mink growth, livability or fur quality to that obtained on the control ration. Male mink were subjected to various artificial lighting regimes to study the effect on spermatogenesis. The mink were castrated at frequent intervals. Testes and epididymides weights, as well as histological sections were compared with similar tissues from control animals that received natural light. The artificial lighting regimes had little, if any, effect on spermatogenesis.

SUPPORTED BY U.S. Dept. of Agriculture

4.0664, FUR ANIMAL STUDIES (MINK)

R.J. AULERICH, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL01039)

OBJECTIVE: Develop techniques for semen collection and artificial insemination of mink. Evaluate new sources of low-cost feed ingredients for mink. Study the effects of feed contaminants on mink.

APPROACH: Study the basic characteristics of mink semen and devise methods of obtaining semen and artificially inseminating mink. Compare performance of mink fed 5 freshwater fish diets with that of rations containing marine fish. Conduct mink feeding trials involving pesticides. Determine the lethal dose of pesticides for mink and analyze tissues for pesticide residues and pathologic lesions. Conduct lab tests and mink and rat feeding trials to determine the factor(s) responsible for reproductive failure in mink attributed to the feeding of coho salmon.

PROGRESS: A technique for electro-ejaculation of male mink has been developed and the basic characteristics of mink semen described. The mean semen volume per ejaculate was .021 ml. Methods of artificial insemination for mink are being studied in an attempt to perfect a practical approach to AI in this species. Studies on mink fed freshwater fish presscake (alewife, sucker, smelt, bullhead and carp) have shown that these species generally did not perform as well as raw marine fish (ocean perch and whiting) in the diet of mink during the critical periods of growth and reproduction. Chubs, perch and coho salmon from the Great Lakes are presently being evaluated for mink feeding and an attempt is being made to elucidate the reason(s) for the inferior reproductive performance in mink fed the freshwater fish. Feeding trials involving laboratory rats and mice, Japanese quail and ferrets are also being employed in the investigation. The effects of diets containing various levels of chlorinated hydrocarbon pesticides (DDT, DDE, TDE and dieldrin) on growth, reproduction and survival in mink are being investigated. Lethal dosages for these pesticides for mink have been determined and the symptoms and pathologic lesions associated with pesticide poisoning studied. Selected tissues (brain, fat and liver) and milk from mink fed known quantities of these pesticides are being analyzed. Methods of reducing pesticide residue accumulation in mink fed diets containing 'high' levels of pesticides are also being investigated.

SUPPORTED BY U.S. Dept. of Agriculture

4.0665, EFFECTS OF PHYSIOLOGICAL ENVIRONMENT ON CELLULAR HOMEOSTASIS, PROTEIN METABOLISM AND NUTRITION

W.G. BERGEN, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL03064)

OBJECTIVE: Effects of level of dietary protein or amino acid intake, fasting or glucose supplementation on protein synthesis capacity and structural integrity of protein synthesis machinery. Effect of important commercial pesticides on nucleic acid metabolism, protein synthesis, and mitochondrial energetics.

APPROACH: Dietary protein or amino acid level, energy infusions, experimental protein/calorie imbalance, chronic treatment with important pesticides. Parameters: Protein synthesis capacity, body amino acid pools, mitochondrial energetics, nucleic acid metabolism, structural integrity of polysomes.

PROGRESS: The effect of the pesticide dieldrin on liver mitochondrial metabolism and liver and muscle protein synthesis has been studied. Dieldrin inhibits electron transport in mitochondria but does not cause uncoupling of oxidative phosphorylation. Currently we are locating the site of electron transport blockage by dieldrin in the mitochondrial electron transport system. Dieldrin was injected every other day at a low and high dose level to rats for 2 months. Administration of the low dose level of dieldrin depressed liver and muscle amino acid incorporation while the high dose level did not modify liver or muscle protein synthesis.

4.0666, THE ACCUMULATION AND EXCRETION OF DIELDRIN IN DAIRY HEIFERS AND COWS

L.D. BROWN, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (033106870123)

OBJECTIVE: Determine the extent of dieldrin residue carryover from heifers to first lactation and; evaluate the effects of feeding practices on the persistence of dieldrin residues in tissues and milk of dairy cows.

APPROACH: Pregnant dairy heifers will be fed dieldrin at various intervals pre-partum. The level of residue in tissues will be determined pre-and post-partum. The extent of placental transfer of dieldrin to new born calves will be related to the period of dieldrin feeding. Various feeding practices will be studied to determine their effect on dieldrin excretion in the milk of these heifers after parturition.

PROGRESS: A major, previously unreported finding was that significantly greater dieldrin storage occurred in body fat when pregnant dairy heifers were contaminated earlier in gestation. Heifers contaminated at 180 and 120 days prepartum stored three and two times as much dieldrin, respectively, as did animals contaminated starting 60 days prepartum. Once nonlactating dairy heifers were contaminated with HEOD, very little was eliminated from the body until lactation began. Placental transfer of HEOD did occur into calves. A combination of blood HEOD concentration in the dams and length of time the developing fetus is in contact with blood containing HEOD influences the amount of pesticide transferred to the fetus. No difference in fetal levels were noted regardless of stage of gestation during which the dams were contaminated. With levels of contamination used in these experiments female calves contaminated in utero with HEOD will probably not contain sufficient levels of HEOD at parturition to produce detectable levels in their milk. Milk was the primary excretory pathway of HEOD in dairy cattle. Feedstuffs contaminated with chlorinated hydrocarbon pesticides should not be fed to growing dairy heifers as previously recommended in several states.

SUPPORTED BY U.S. Dept. of Agriculture

4.0667, EFFECTS OF PESTICIDES ON NON-TARGET ORGANISMS

J.W. BUTCHER, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00720)

OBJECTIVE: Assess the effect of insectide applications on selected species of microarthropods which are important in the process of organic decomposition. Examine the effect of insecticides on selected species of microarthropods under laboratory conditions in regard to their biology, development, and ecological displacement. Investigate the effect of insecticides on the interaction between phytophagons insect species and the plants parasite of jack pine, Melampyrum lineare.

APPROACH: Monitor Collembola, Acari, and Opiliones species within dieldrin treated and untreated woodlots in Monroe

County. Determine changes in abundance and species complex in relation to residue persistance. A series of test plots have been established on South campus study the effects of dieldrin and DDT on the abundance and changes in the species complex of Collembola. Acari, and other soil arthropods. These plots are on cultivated land and will be planted to corn yearly. Collembola and Acari are being cultured under laboratory conditions. Individual species are being used to determine their role in the process of organic decomposition. The consequence of insecticide application on this process is being studied. Studies are underway to determine the effect of feeding of various phytophagous insect species on Melampryum lineare. Field plots have been set up and differences in feeding due to insecticide application are being compiled.

PROGRESS: Field work began in the Summer of 1969, on a project monitoring the degradation and movement of DDT in soil and litter forest microarthropod food chains. The DDT was introduced directly into the food chain by feeding it to a species of collembola which could be reared in large numbers in the laboratory, and then releasing the collembola in enclosed plots in a forest situation. Samples were then taken of the litter and soil at various intervals during the next 30 days to obtain microarthropods for taxonomic identification and analysis of DDT and its metabolites. A concurrent study of soil and litter macroarthropods is also taking place, and field experiments will continue during the Summer of 1970.

SUPPORTED BY Michigan State Government

4.0668, METABOLISM OF PESTICIDES BY RUMEN MICROBIOTA AND FACTORS INFLUENCING ABSORPTION

R.M. COOK, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL03001)

OBJECTIVE: Determine role of rumen and G.I. tract microbiota on metabolism of pesticides; identify any bacteria that degrade pesticides; note if pesticides alter normal rumen metabolic pathways; study site and nature of absorption process of pesticides and factors influencing absorption.

APPROACH: In vitro fermantation using rumen fluid, washed cells or pure cultures will be used to study microbial metabolism of pesticides. Attempts to find bacteria that degrade pesticides will be made. Many known enzyme systems of rumen microbiota will be used to determine if pesticides alter these normal processes. Absorption area in G.I. tract will be determined and attempts to reduce absorption by diet additives, i.e. mineral oil or other antagonists will be quantitated.

PROGRESS: Activated carbon has been shown to bind pesticides in the gut of cattle and increase their excretion in the feces. A field trial was conducted in Michigan to determine the effects of long term activated carbon feeding to lactating Holstein cows on health, milk production and reproduction. The carbon was fed to 12 cows for 1 year at the rate of 1 lb of carbon per head per day. The carbon did not affect health, production or reproduction. Activated carbon was fed to goats along with dieldrin to determine the effectiveness of carbon in binding dieldrin metabolities. The carbon binds the metabolites. Consequently, feeding is more effective in clearing dieldrin than previously thought because part of the dieldrin is changed to metabolites that are adsorbed by carbon. Studies are being conducted to determine whether or not there is selective binding of DDT metabolites by activated carbon.

SUPPORTED BY Michigan State Government

4.0669, FACTORS AFFECTING PLACENTAL TRANSFER, METABOLISM AND EXCRETION OF PESTICIDES IN ANIMALS

R.M. COOK, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00794)

OBJECTIVE: Determine whether body stores of dieldrin in rats can serve as a source for placental transfer. Ascertain effects of various organic compounds on placental transfer of dieldrin. Evaluate the degree of placental transfer of dieldrin when fed either before or during gestation. Explore the possibilties of placental transfer to second generation offspring via turnover of body stores in females contaminated in utero. Investigate specific fraction(s) of lipids responsible for distribution of residues in body fat.

APPROACH: Mature female Spartan rats will be fed dieldrin- containing feed with and without heptabarbital before breeding and during gestation. Fat biopsy samples will be taken at regular intervals and separated into neutral and phospholipids to determine residue distribution in each lipid class. Dieldrin residues will be determined quantitatively in new born pups and correlated with dieldrin intake and body storage in the mothers. Females from contaminated litters will be raised and bred at maturity to investigate placental transfer to the second generation.

PROGRESS: The anticonvulsant drug dilantin has been shown to decrease the storage of DDT in human and rats. Studies were conducted to determine whether or not dilantin will increase the rate of dieldrin clearance from rats. The preliminary data with rats indicate that dilantin will increase dieldrin excretion in rats. Trials are being conducted to determine whether or not dilantin will increase the rate of dieldrin excretion in ruminants.

SUPPORTED BY Michigan State Government

4.0670, PESTICIDE METABOLISM IN BEEF CATTLE

R.M. COOK, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL03039)

OBJECTIVE: Establish conditions under which tissue residues occur in beef cattle; effect of pesticide on feedlot performance; identify metabolites of various pesticides.

APPROACH: Tissue analysis of steers after a prescribed feeding period and dosage; study effect of low level feeding of lindane on feedlot performance; identification of metabolites resulting from the feeding of either lindane or ruelene. Study enzyme system involved in the metabolism of these pesticides.

PROGRESS: Work is in progress to try to develop an assay for the enzyme system in liver microsomes that metabolizes heterocyclic-type pesticides such as dieldrin and also lindane. It is important to isolate and study the control of the enzyme system. This will provide a basis for finding ways to increase the activity of the enzyme. The water-soluble vitamin inositol will cure fatty liver disease in poultry. The vitamin is metabolized to glucuronic acid. These and other aspects of the metabolism of inositol suggest that this vitamin could be effective in increasing the rate of pesticide excretion in ruminants. Preliminary inositol-feeding trials using rats indicate that the vitamin will increase pesticide clearance. These studies are being extended to include goats, sheep and steers.

SUPPORTED BY Michigan State Government

4.0671, FACTORS AFFECTING INSECTICIDE RESIDUES IN MILK

R.M. COOK, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00955)

OBJECTIVE: Determine sources of contamination under high residue conditions; determine the carry over of contamination from young dairy animals to lactating animals; determine the rate of residue disappearance, removal of objectionable residues.

APPROACH: Survey of problem herds to pinpoint contaminated animals; review feed sources, water supplies, pest control programs; determine source of exposure; determine rates of dissipation from the animal under normal and imposed experimental conditions; study growth, gestation and lactation on residue disappearance and evaluate methods of removing contamination.

PROGRESS: HEOD (dieldrin) was fed to 8 lactating Holstein cows at the level of 0.11 mg/kg body weight daily for 6 weeks. One half of the cows were simultaneously fed phenobarbital at the level of 10 mg/kg body weight daily. The objectives of the experiment are to correlate blood levels of HEOD with levels in body fat, to estimate the amount of HEOD excreted and the amount retained in the body, to determine the number and amount of HEOD metabolites stored and excreted and to study the effect of phenobarbital on these parameters. If blood levels of HEOD are correlated with body fat levels, then it may be possible to estimate the total body load of a pesticide by measuring the

level in the blood. A high level of HEOD was fed in order to obtain enough HEOD metabolites to measure readily. Blood, urine, feces, milk and body fat have been analyzed for HEOD and the data is presently being summarized. Analysis of the samples for HEOD metabolites has not been completed.

SUPPORTED BY U.S. Dept. of Agriculture

4.0672, ANALYSIS OF BIO-ACTIVE CHEMICALS FOR POSSIBLE HAZARDOUS PROPERTIES
R.A. HOOPINGARNER, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL03025)

OBJECTIVE: The objectives of this project is to examine insecticides and other pesticides for possible hazard to human health.

APPROACH: The methods used are to examine cells and tissues for cytological and genetic damage. Cell cultures, organ cultures and intact tissues are used depending upon the chemical to be tested. Chromosome damage and other cytological aberrations are used as indication of potential hazard.

PROGRESS: The project examined 40 persons per month for leucocyte chromosome abnormalities. The 20 exposed persons were persons highly exposed from spray operations. The exposed group had more aberrations in the month of July then the control. All other periods were not significantly different. This difference compared favorably with the previous year when July was the most significant month/a period following and during the highest pesticide use.

SUPPORTED BY Michigan State Government

4.0673, BIONOMICS AND CONTROL OF INSECT PESTS AFFECTING SMALL FRUITS
A.J. HOWITT, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00954)

OBJECTIVE: Reduce the cost and hazard of controlling pests through: Insecticides of low mammalian toxicity; Reducing number of sprays reducing the hazard of drifting; Investigate use of attractants, repellents, and resistant varieties.

APPROACH: Bionomics and chemical control with materials of low mammalian toxicity conducted. Includes the grape berry moth, raspberry root borer, raspberry cane borer and and blueberry maggot.

PROGRESS: Work was initiated on a ULV and LV ground sprayer for blueberries and grapes. Three compounds of low mammalian toxicity Imidan, Lannate, and Malathion gave outstanding control of blueberry maggot when applied to blueberries with a low volume ground sprayer. Low volume applications of Guthion and Imidan gave excellent control of grape berry moth when applied with the low volume applicator.

SUPPORTED BY U.S. Dept. of Agriculture

4.0674, MAGNITUDE AND NATURE OF POLYCHLORINATED BIPHENYLS IN COHO SALMON
N.C. LEELING, Michigan State University, School of Agriculture, *East Lansing, Michigan* 48823

The proposed research plan involves laboratory investigations aimed at determining the amount of polychlorinated biphenyl (PCB) and terphenyl compounds present in Coho salmon from Lake Michigan and the chemical identity of each major component. The main approach will entail organic solvent extraction of salmon samples, column chromatographic separation of chlorinated components into a DDT-complex fraction and a PCB fraction and a gas chromatographic-mass spectrometric characterization of the individual components.

The data will provide an accurate determination of PCB residue levels and their composition in Coho salmon, thus permitting a rational interpretation of the significance of these compounds with respect to the fish.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

4.0675, PATHOLOGIC EFFECTS OF BIOLOGICALLY ACTIVE CHEMICALS USED IN THE ENVIRONMENT - THE TOXICITY OF NITRATES
S.D. SLEIGHT, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00964)

OBJECTIVE: Determine the pathologic effects chemicals used in environment. Characterize lesions produced by experimentally administering nitrates and related compounds to animals. Obtain information on the toxic levles of these compounds and/or factors that retard or enhance toxicity. Determine, methods of prevention and control. Improve methods of diagnosis.

APPROACH: Administer nitrogenous compounds to groups of animals. Animals will be necropsied and selected tissues will be processed by histological procedures, biochemical and histochemical determinations will be conducted.

PROGRESS: Studies of dieldrin toxicosis in swine and guinea pigs have shown that the compound can cross the placental barrier in both species. In swine, repeated doses of relatively high levels of dieldrin failed to cause abortions or fetal deaths. Similar doses in guinea pigs resulted in abortions. Concentrations of dieldrin were determined in maternal and fetal tissues of both species with emphasis on brain levels. Simultaneous administration of nitrite apparently did not increase or decrease dieldrin toxicosis. Mild degenerative changes were present in the liver, kidney and adrenals of guinea pigs poisoned with dieldrin. Electron microscopy is being used to evaluate changes in the brain and liver due to acute dieldrin toxicosis. These studies are in progress. Initial studies have shown no evidence of toxicosis in guinea pigs, voles, or sheep fed plants containing high levels of nitrates. This work is being done in cooperation with the Dr. Ries of the Horticulture Department as part of the Pesticide Project and is continuing.

SUPPORTED BY U.S. Dept. of Agriculture

4.0676, THE UPTAKE OF INSECTICIDES BY FRESHWATER MUSSELS AND THE EFFECTS OF SUBLETHAL CONCENTRATIONS OF INSECTICIDES ON THESE MUSSELS
M.E. ZABIK, Michigan State University, Graduate School, *East Lansing, Michigan* 48823

The study will involve the exposure of freshwater mussels to sublethal concentrations of various insecticides. The principal objectives will be: 1) to correlate the amount of insecticide concentrated by the mussel with the concentration in the water; 2) to determine the principal source of insecticide concentrated by the mussel, i.e. from the water directly or from that absorbed by or adsorbed on their food; 3) to determine the main locations in the mussel where insecticides and any metabolites formed are stored; 4) to determine the effect of the insecticides on the filtering rate of the mussels.

From the results obtained it is hoped that the usefulness of the freshwater mussel as a biological monitor of insecticides can be further evaluated.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

4.0677, POTENTIALS FOR REMOVING OR REDUCING PESTICIDE RESIDUES IN FOODS
M.E. ZABIK, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL01043)

OBJECTIVE: Determine the potentials for destroying or lessening pesticide residues in foods prepared by various methods of processing and/or cooking.

APPROACH: Raw and cooked foods will be analyzed after physical separation into appropriate components. Processing and/or cooking procedures will follow standard practices. When feasible, foods will be subjected to chemical and physical measurements and/or sensory evaluations to assess quality.

PROGRESS: For the initial phase of this study, pork loin cuts from animals fed known quantities of Dieldrin were compared with like cuts from an animal fed no Dieldrin. Samples were

cooked by roasting, braising, microwave energy and broiling. Dieldrin residue levels were determined by electron capture gas chromatography following extraction on raw and cooked meat samples as well as braising media and/or drip. The data showed samples cooked by the four methods contained lower Dieldrin residue levels than raw samples. Drip from all cooking methods contained Dieldrin. From the limited data, roasting and broiling appear to be more effective in reducing pesticide levels than braising or microwave energy; however, more research is needed before definite conclusions can be made.

SUPPORTED BY U.S. Dept. of Agriculture

4.0678, THE EFFECTS OF METHOXYCHLOR ON PERCH AND FATHEAD MINNOWS

J.W. MERNA, State Res. & Dev. Division, *Lansing, Michigan* 48926

Objectives: To establish acceptable exposure levels of methoxychlor for fish and other aquatic organisms. This objective will involve long-term exposure to sublethal levels, and their effects on fish growth, on fecundity, survival and production.

Effects on benthic organisms and algae will also be studied by University of Michigan graduate students, but not as part of this research job.

Procedures: Laboratory bioassays of mean tolerance limits of methoxychlor for yellow perch and fathead minnows are being done in aquarium tests at the Saline station. (The tests were started during fiscal 1969-1970, will be completed shortly after July 1, 1970.) The results of these short-term (96-hour) bioassays will be used to select, later, the low-level concentrations which will be dosed to perch and fathead minnows held in experimental streams for 2 years or more.

A raceway is being constructed at the Saline station for the present study, with funds from a FWQA grant. A stream channel will be divided lengthwise (by a concrete wall), and each twin channel will be divided into three segments. The result is a series of 6 experimental stream sections (each 15 feet x 120 feet). Yellow perch and fathead minnows will be established in each of the six stream sections. Two sections will be exposed to a low-level dose of methoxychlor; two, to a higher level; and (as stated above) two receive no dosage. Studied in relation to methoxychlor dosage will be: fecundity, production of young, growth, and fish population level. Brood stock of perch and fatheads will be stocked in September to produce a population of carrying capacity (est.100 lb. per acre) the following spring. Each stream section will get 50 adult perch (6-7 inches) and 300 fatheads; about half will be removed, before spawning, for special studies

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0679, EFFECTS OF METHOXYCHLOR ON FISH

J.W. MERNA, State Res. & Dev. Division, *Lansing, Michigan* 48926

Project and Job Objectives: To establish acceptable exposure levels of methoxychlor for fish and other aquatic organisms.

Procedures: Acceptable exposure levels will be determined by measuring the effects of long-term exposure to sub-lethal levels of methoxychlor by laboratory bioassays and in natural stream conditions. Effects on fish growth will be established in the laboratory with bioassays on two species of fish. Effects on fecundity, survival and production of fish populations, and production of benthic organisms, will be established from studies in controlled stream environments. The laboratory bioassays should be completed by June 30, 1970. However construction of the stream facilities will require most of this year (1960) and the experimental work may not begin until the following fiscal year.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0680, EFFECTS OF DISSOLVED OXYGEN, TEMPERATURE AND POTENTIAL TOXICANTS UPON MACROINVERTEBRATES (NON-ARTHROPODS)

M.J. IMLAY, U.S. Dept of the Interior, Federal Water Quality Admin., *Duluth, Minnesota* 55804

Effects of dissolved oxygen, temperature and toxicants (such as $CuSO_4$) on commercially valuable fresh-water clams and on fish food chain macroinvertebrates such as snails, leeches, scuds, insects, and flatworms will be studied.

Relation of cellular changes and daily activity patterns to toxicant or environmental stress and relation of mass filter-feeders (clams and sponges) to bacterial water quality will also be investigated.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

4.0681, A TISSUE ENZYME ASSAY FOR CHLORINATED HYDROCARBON INSECTICIDES

L.K. CUTKOMP, Univ. of Minnesota, School of Agriculture, *Saint Paul, Minnesota* 55101

The objective is to determine whether the sensitivity of the ATPase enzyme system in fish can be used to measure toxicity or adverse effects of chlorinated hydrocarbon insecticides in pesticide-polluted waters.

ATPase enzymes have been shown to be sensitive to DDT and related chemicals, with some metabolites, such as DDA, having virtually no effect.

Other chlorinated hydrocarbons, the cyclodienes, also affect the enzyme system, but in a way which is usually distinguishable from DDT inhibition. Organophosphate and carbamate insecticides have not been found to effect ATPase significantly.

A secondary objective is to determine which tissues and subcellular fractions are the most sensitive to the compounds. Tissues being studied are brain, muscle, liver, and kidney. Because DDT, in particular, shows some different activity due to temperature, this aspect is also being studied.

Assays for enzyme activity are being carried out on the blue gill fish and studies will continue on this species which is sensitive to the insecticides, easily reared and collected, and occurs in rather diverse aquatic environments.

Acute and chronic exposure of the fish will be employed to relate to the findings of inhibition of the enzyme system.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

4.0682, MODE OF ACTION OF INSECTICIDES AS RELATED TO INSECT METABOLISM AND BEHAVIOR

L.K. CUTKOMP, Univ. of Minnesota, Agricultural Experiment Sta., *Saint Paul, Minnesota* 55101 (MIN-17-047)

OBJECTIVE: Determine the effects of insecticides, particularly chlorinated hydrocarbons and pyrethrum on the enzyme systems, adenosine triphosphatase (ATPase) both in vitro and in vivo. The insecticidal effects and the ATPase enzyme activity will also be related to periodic (rhythmic) physiological events in the insect.

APPROACH: Accepted current biochemical determinations will be made of the ATPase enzyme system in nervous and muscle tissues of American cockroaches, honey bees and other insects. Known dilute concentrations of DDT, other chlorinated hydrocarbons and pyrethrum will be tested for specific inhibitory effects on the enzyme system. In addition, the specific activity of the enzyme system and insecticide sensitivity will be related to periodicity in the American cockroach, using established light and dark lighting regimes during a 24-hour day.

PROGRESS: Basic information on the activity of the ATPase enzyme system has been determined in muscle and nerve cords of American cockroaches. The inhibition of the enzyme has been determined by in vitro and in vivo experiments. Alpha and gamma chlordane gave much greater inhibition of the ATPase enzyme in vitro than in vivo. When roaches were injected the maximum inhibition was about 33% in roach muscle compared to over 85% inhibition on the isolated enzyme system. DDT at 1 part per million also inhibits Mg research pertains to development of a tissue enzyme assay for chlorinated hydrocarbon insecticides in fish. Five tissues in bluegill fish have been tested for ATPase activity and sensitivity to p,p'DDT. The highest enzyme activity is greatest in kidney and brain, but the greatest enzyme sensitivity to DDT occurred in muscle of fish as well as in cockroach, honeybee, and rabbit. Muscle ATPase from lake trout muscle was also more sensitive to DDT when compared to brain ATPase. The percent of Na-K ATPase (ouabain inhibited) in relation to total ATPase was

as follows: brain, 56.3%; kidney, 53.5%, liver, about 11%, muscle 7.4%; testis, 9.9%. A comparison of effectiveness of insecticides on corn rootworm adults has indicated increased resistance of insects to diazinon and phorate when compared to determinations in 1968. Some rhythmicity studies on oxygen consumption have been carried out with Tribolium confusum.

SUPPORTED BY U.S. Dept. of Agriculture

4.0683, HERBICIDE STUDIES EMPLOYING IN VITRO CULTURE METHODS

A.J. LINCK, Univ. of Minnesota, Agricultural Experiment Sta., *Saint Paul, Minnesota* 55101 (MIN-21-077)

OBJECTIVE: Study of the physiological action and effects of selected herbicides in tissues or intact organs isolated from plants and cultured in vitro.

APPROACH: Standard methods of procedure for callus and organ culture will be used. These methods involve the sterile isolation of either stem tissue (for callus culture) or the fruit (for organ culture) from plants and their transfer to artificial media. Callus culture will be carried out with tobacco stem tissue grown on a modified White's solid medium and the culture of excised tomato fruits on a similar liquid medium, with the appropriate basal hormones as additives. Each herbicide in the study will be tested over a range of concentrations. After the initial technical problems have been worked out several herbicides will be selected for studies on their physiological effects and persistence in tissue or organs cultured in vitro under sterile conditions.

PROGRESS: A complete tissue culture laboratory was set up and included culture room, sterile transfer room and facilities for growing callus at high and low light intensities and in darkness, with humidity and temperature control. The effect of N-1-naphthylphthalamic acid (NPA) on callus growth and bud formation was studied mainly using tobacco pith callus. The effect of the interaction of NPA with IAA and kinetin was studied. It was found that callus growth was promoted when NPA was supplied at a concentration of 0.5 mg/l with 0/4 mg/l of kinetin; or, when NPA was supplied at a concentration of 5 mg/l in the absence of kinetin; in both cases the concentration of IAA was 2 mg/l. When the IAA concentration was at 2 mg/l and without kinetin, NPA at 50 mg/l inhibited growth. Without kinetin, in the presence of 2 mg/l IAA, NPA at 50 mg/l caused a reduction in amino acids, protein and nucleic acid in calluses grown on test medium for 5 weeks. However, with the same concentration of IAA and kinetin, NPA at 5 mg/l promoted the nucleic acid content in callus compared to the control. Based on the growth tests and the nucleic acid analyses kinetin was found to counteract NPA inhibition. Hence, NPA might affect growth by interfering with auxin-cytokinin controlled nucleic acid synthesis.

SUPPORTED BY U.S. Dept. of Agriculture

4.0684, CONTROL OF INSECT PESTS OF VEGETABLES BY INSECTICIDES AND PLANT RESISTANCE

E.B. RADCLIFFE, Univ. of Minnesota, Agricultural Experiment Sta., *Saint Paul, Minnesota* 55101 (MIN-17-042)

OBJECTIVE: Contribute to the development of improved control measures for the insects affecting vegetable production through research on insecticides and insect resistance in crop plants.

APPROACH: New insecticides, formulations, rates, methods and timing of application will be investigated. Present control practices will be continually evaluated that we may be alert to the development of new problems, e.g., development of resistance, pest resurgences, occurrence of new or traded pests, accumulations of insecticide residues. We will investigate the inherent resistance of certain plants to insect attack. Emphasis will be given to research on insect resistance in the wild Solanum species. We intend to investigate the inheritance of aphid resistance and possible incorporation of this characteristic into the cultivated potato from wild sources. The mechanism of this resistance will be investigated.

PROGRESS: 379 Solanum introductions including approximately 300 never previously evaluated were tested as possible sources of resistance to green peach aphid, Myzus persicae, and potato aphid, Macrosiphium euphorbiae. Species typically resistant to M. persicae included brachistotrichum, bulbocastanum, cardiophyllum, michoacanum, sanctae- rosae, stenophyllidium and stoloniferum; to M. euphorbiae, bulbocastanum, canasense, cardiophyllium, chomatophilum, commersonii, hjertingii, multidissectum, polytrichon, and stoloniferum. F(1) hybrids incorporating stoloniferum and tuberosumphureja were as resistant to M. persicae as the wild parent, similarly F(1) OP progenies incorporating stoloniferum or sanctae-rosae were resistant. Carbofuran and phorate gave wireworm (Limonius and Melanothus spp.) control approaching that obtained with the same rate AI/A of chlordane. M. persicae was most effectively controlled with 1/2 lb. Monitor or 3/4 lb. endosulfan. Presently recommended materials gave excellent potato flea beetle, Epitrix cucumeris, control. Larvae of imported cabbageworm, Pieris rapae, and adult cabbage maggot, Hylemyia brassicae, differ significantly in their susceptibility to topical applications of parathion according to the species and variety of the host from which they were collected. Cabbage selections made in 1968 on the basis of differential resistance to P. rapae showed consistent differences for this character in 1969.

SUPPORTED BY U.S. Dept. of Agriculture

4.0685, FACTORS INVOLVING PESTICIDES IN MILK PRODUCTS

B.F. BARRENTINE, Mississippi St. University, Agricultural Experiment Sta., *State College, Mississippi* 39762 (MIS-3-206-0739)

OBJECTIVE: Study on-the-farm practices which contribute to pesticide residue occurrence in milk. Pesticide residues will be determined in forages following cotton crops where known insecticide applications have been made: determined in feeds and forages grown to determine the importance of drift from applications made on other crops; determined in commercial feeds and forages.

APPROACH: Samples will be analyzed for DDT at various stages of growth of oats planted on land with several levels of contamination. Samples of forage crops taken for pesticide analysis at several distances from fields where pesticides were used. Samples taken of commercial feeds and forages for analysis.

PROGRESS: Milk samples from both Grade A and commercial producers throughout the State have been analyzed for pesticides. The north-east portion of the State is the only area that has a problem with pesticides in milk. This is an area where cotton production and dairying occurs on the same or adjoining farms. Producers whose milk was high in pesticides have been interviewed to determine their pesticide practices. Misuse of pesticides on and around the dairy farm appears to be the major cause of excessive pesticide residues in milk. This misuse, in spite of various educational programs, continues to occur. The misuse referred to varies from direct application on non-approved pesticides to dairy cattle to inadvertent aerial spraying of pastures and feeds to be used by dairymen.

SUPPORTED BY U.S. Dept. of Agriculture

4.0686, COMMUNITY STUDY ON PESTICIDES

B.F. BARRENTINE, Mississippi St. University, Agricultural Experiment Sta., *State College, Mississippi* 39762 (MIS-8-240-0782)

OBJECTIVE: Determine types of pesticides to which the human population is exposed, the nature and degree of exposure, ecologic factors which affect their exposure, and characteristics of the subject population. Determine levels of selected pesticides in human tissues and the environment. Determine consequences of chronic and acute exposure and relationships of factors and conditions affecting frequency, distribution, severity and long-term consequences of pesticide-caused illness, or of pesticide-caused biochemical changes.

APPROACH: Investigate acute pesticide poisoning in Washington, Bolivar and Sunflower counties. Undertake a long-term intensive physical, neurological, chemical and medical surveillance of approximately 145 persons exposed to pesticides and 20 persons not exposed. Investigate the relative toxicities of the metabolic products of parathion and methyl parathion.

PROGRESS: In accordance with the long range objectives of the project, the study of people occupationally exposed to pesticides has continued. Exposure groups are characterized as heavy,

medium, and controls. These groups are represented in the same order by pesticide ground applicators, managerial personnel, and people not working with pesticides. It has been shown that there is a seasonal trend in the amount of DDT found in the blood of these study groups. The DDT blood levels reach a peak in July and August for the exposed population and drop to a minimum around mid-winter. The control population shows the same trend, but to a lesser degree. Studies are underway to determine the source of pesticide exposure in the control group. A study of the clinical findings has not revealed any significant differences between exposure groups. Clinical and enzyme tests on the blood of exposed and control participants will be continued. The procedures will be more rigidly controlled and made more precise. Efforts to detect subtle blood chemistry differences will be intensified.

4.0687, CONTROL OF THE IMPORTED FIRE ANT

H.B. GREEN, Mississippi St. University, Agricultural Experiment Sta., *State College, Mississippi* 39762 (MIS-3-206-1041)

OBJECTIVE: Test for insecticides that leave no harmful residue. Test baits, attractants and methods of application. Make harmful studies. Study effect of fire ant venom on several forms of life.

APPROACH: Mounds in pasture and meadow land will be treated with various insecticides. Lab and field studies will be made with baits and attractants. Biological observations will be made. Fire ant venom will be isolated and tested on fish and other vertebrae animals.

PROGRESS: Studies of the changes in nutrient levels each month of the year were made for the castes of workers. The major form had the highest levels. The highest lipid level was during the fall and winter. Glycogen was similar, but the increase was less. Proteins were similar, except that there was a sharp drop in May through July. It may be that the high levels in the fall of the year are in preparation for winter; but it is possibly as a result of a lower level of brood production at a time when there is an abundant supply of food. The lower levels of protein in early summer may be a reflection of a high replacement of workers following the spring late brood production. Further studies of this work may be of value in future bait acceptance. During collection of males in the laboratory from field reared captive colonies, it was noted that females started their flights later in the day than did the males. No evidence of copulation was noted in any of the laboratory collections.

SUPPORTED BY U.S. Dept. of Agriculture

4.0688, BIOLOGY AND CONTROL OF THE HELIOTHIS COMPLEX ON COTTON

F.A. HARRIS, Mississippi St. University, Agricultural Experiment Sta., *State College, Mississippi* 39762 (MIS-3-206-1035)

OBJECTIVE: Determine the relative incidence of Heliothis zea and H. virescens on cotton during the season and the role of alternate host plants on populations on cotton. Determine the effectiveness of chemicals for control of Heliothis species. Study the basis of DDT resistance in Heliothis species. Evaluate the role of predators and parasites in bollworm control under various insect control programs and other cotton production practices. A comparative study of the basic biology of the Heliothis species on cotton and other host.

APPROACH: Larval collection will be made at periodic intervals from cotton in selected areas of the state throughout the growing season and identified. Eggs will be collected and larvae reared to eliminate the selection effect of insecticides on the two species. Dosage- mortality curves will be obtained for all currently used chemicals on selected populations collected throughout the state. Collections for tests will include larvae collected from cotton as well as other host plants and of wild adult populations. Laboratory strains of DDT resistant and susceptible strains of bollworm and tobacco budworms will be maintained. The fate of various insecticides applied to the larvae will be studied by various chemical analyses, radioassay and chromatographic techniques. Ecological studies will be conducted in fields subjected to various control and cultural programs to determine their effects upon natural control factors.

PROGRESS: Comparison of Heliothis larval infestation in cotton fields not treated with insecticide and cotton fields treated with aldicarb indicated that predators in the untreated fields reduced Heliothis larvae population by as much as 50%. A preparation of delta- endotoxin of Bacillus thuringiensis (HD-1) tested as a spray application to cotton showed promise for Heliothis control. New Heliothis nuclear polyhedrosis virus formulations showed improved activity in Heliothis control over the old preparations. H. virescens populations in the Mississippi Delta show increased levels of resistance to Toxaphene-DDT and the initial stages of development of resistance to methyl parathion is indicated.

SUPPORTED BY U.S. Dept. of Agriculture

4.0689, DISTRIBUTION, ABUNDANCE AND CONTROL OF HELIOTHIS SPP. IN COTTON

F.A. HARRIS, Mississippi St. University, Agricultural Experiment Sta., *State College, Mississippi* 39762 (MIS-3-207-1032)

OBJECTIVE: Determine the importance of the various host plants in contributing to the seasonal and long term abundance and the local dispersal patterns of each Heliothis species among the host plants. Study the occurrence and biochemical basis of insecticidal resistance in Heliothis populations within the Southern Region. Develop procedures for using parasites, predators, pathogens, plant and insect hormones, sterile males, pheromones and insecticides for Heliothis control. Screen and evaluate the cultivated and wild species of Gossypium and Glycine for morphological and physiological plant characters which provide plant resistance, tolerance, and 'nonpreference' to Heliothis species. Integrate information obtained in the objectives into new pest management systems which will place less dependence on chemical pesticides.

APPROACH: Heliothis population surveys in cotton and soybeans. Monitor insecticide resistance. Study levels of biological control in cotton and screen insecticides. Screen cotton and soybeans for host plant resistance. Integrated control research.

PROGRESS: Late season survey of Heliothis larval populations in cotton in Mississippi showed the portion of H. virescens to range from 10% in light insecticide use areas to 100% in heavy insecticide use areas. The Heliothis population on soybeans in Mississippi was found to consist of 10 to 17% H. virescens. Aldicarb systemic insecticide applied sidedress to cotton reduced insect predators and resulted in an increased Heliothis infestation. A preparation of delta-endotoxin of Bacillus thuringiensis (HD-1) showed promise for Heliothis control in cotton and soybeans. New Heliothis nuclear polyhedrosis virus formulations showed increased activity over the old formulations. H. virescens in the Mississippi Delta show increased resistance to Toxaphene-DDT and initial development of resistance to methyl parathion is indicated.

4.0690, BIOLOGICAL AND INTEGRATED CONTROL OF COTTON INSECTS

M.L. LASTER, Delta Branch Experiment Sta., *Stoneville, Mississippi* 38776 (MIS-SUI-0014)

OBJECTIVE: Determine seasonal populations and fluctuations of major predators in cotton fields; study the role of specific predators in cotton insect control; study surrounding areas as reservoir habitats for predators and to study the effects of insecticides on predator and pest species.

APPROACH: Samples will be taken to determine predator populations. Close observations to determine the role of specific predators in cotton insect control. Samples will be taken to determine reservoir areas for predators. Effects of insecticides on predators will be studied.

PROGRESS: Seasonal collections indicated that lady beetles, Nabis, and Geocoris species were the dominant predators in cotton fields during early season and spiders, 90% of which were the striped lynx, Oxyopes salticus Hentz, became dominant in mid- and late-season. All predators were adversely affected by applications of insecticides and were almost eliminated from the fields after two applications to control plants bugs. Spiders were less affected by methyl parathion than by carbaryl, toxaphene plus DDT, and azinphosmethyl.

4. PESTICIDES

SUPPORTED BY Mississippi State Government

4.0691, ROLE OF BENEFICIAL INSECTS IN COTTON INSECT CONTROL
M.L. LASTER, Delta Branch Experiment Sta., *Stoneville, Mississippi* 38776 (MIS-SUI-0107)

OBJECTIVE: Determine species of predators in cotton fields and their abundance throughout the season. Evaluate effectiveness of beneficial insect populations in the overall cotton insect control program. Determine effects of various insecticides on beneficial and pest species.

APPROACH: Seasonal populations and fluctuations of major predators in cotton fields will be determined. Beneficial species in the field will be studied from the standpoint of abundance, feeding habits, and ability to suppress a pest population. The effects of different insecticides and dosages on both predator and pest species will be studied in the field.

PROGRESS: Heliothis larvae were collected from a measured area of re-growth cotton in 10 fields during mid-October, 1969. These larvae were held in 1 oz plastic cups, on artificial media. Periodic observation revealed that 28 percent of the larvae were parasitized by Hymenoptera and Diptera species which have not been postively identified.

SUPPORTED BY Mississippi State Government

4.0692, EFFECT OF CHEMICALS ON BENEFICIAL INSECTS
T.R. PFRIMMER, Delta Branch Experiment Sta., *Stoneville, Mississippi* 38776 (MIS-SUI-013)

OBJECTIVE: Study the reduction of species of beneficial insects by the use of various toxicants applied for control of cotton insects. Determine the relative toxicity of the chemicals tested to specific beneficial insects.

APPROACH: Insecticides are sprayed with conventional ground equipment. Sweeping records made at periodic intervals to determine the kind and number of beneficial insects which are killed. Speed of kill as well as residual toxicity of the compounds are compared.

PROGRESS: The use of systemic insecticides as granules at planting or as seed treatments has little effect on populations of beneficial insects and spiders present in the cotton field at the time squaring begins. Any effect on the population seems to be an indirect one caused by the removal of the prey of the predators and parasites. In some cases there have been more beneficial insects on systemic treated cotton early fruiting than on untreated cotton. This appeared to be due to bigger, more vigorous plants in the treated plots resulting from thrips control. The use of systemic insecticides at early fruiting as granule side-dress treatments or liquid stem treatments results in a reduction of certain predators. Insecticide sprays on seedling cotton have little effect on the population of beneficial insects and spiders present when squaring begins. Spray applications after squaring begins will greatly reduce the population of beneficial insects. Following 1 application beneficials will move back into the field if there is a source of supply outside the treated area. This is especially true following the use of a short residual material such as methyl parathion. Various insecticides have differing degrees of effect on beneficial population. In general, the insecticides which are the least toxic to the beneficial insects are also less toxic to harmful insects. Two or more spray applications of most insecticides will completely eliminate the beneficial insect and spider population.

SUPPORTED BY Mississippi State Government

4.0693, A STUDY ON THE CORRELATION BETWEEN INSECT CONTROL AND BEEF PRODUCTION
R.H. ROBERTS, Delta Branch Experiment Sta., *Stoneville, Mississippi* 38776 (MIS-SUTLP-1)

OBJECTIVE: Investigate the effects of insect control on beef animals under typical pasture grazing conditions. Individual weight gains will be compared between two groups of yearling beef steers. One group will be treated twice daily with insecticide to protect them from insect attack. The other group will be untreated. Weight gains will be obtained every two to four weeks. The effect of insect control will be followed through to the end of feed lot testing.

APPROACH: Two groups of 10 yearling beef steers will be placed on grazing pastures. Each pasture will be 4 acres in size and grazing cover consists of Coastal Bermuda or Coastal Bermuda plus clover and fescue. Weekly observations will be made on the animals to determine the type of flies present and the degree of control obtained by the treatment. Also, bait traps will be run in the same vicinity. The basic criteria for measuring the efficiency of the insect control will be the comparison between the individual weight gains of the two groups.

PROGRESS: The data from several year's study on this project has shown that the method of treatment bears an important relationship to the weight gains of the animal. The data from the first year's study indicate that the method used to treat the cattle for insect control had a detrimental effect on weight gains. In that study, an automatic sprayer using an oil-base spray was used to treat the animals. The treated groups at times showed a great reluctance to pass through the spray unit to obtain water. In addition, a number of animals had epidermal reactions that were quite severe caused by the oil-based spray. During the following year when a water-based spray was used, the animals were not sufficiently protected from insect attack. In the third year of this study, animals were pen-sprayed. Two groups of 14 steers were used; half the steers in one group were sprayed weekly, half the steers in the other group were sprayed bi-weekly. No difference in weight gains was found between the treated and control in either group. After 84 days in a feed lot, the weekly sprayed group averaged 3.3 lbs per day gain, while the bi-weekly group averaged 2.94 lbs. In a separate group of steers that were pen-sprayed every three weeks, the treated animals had higher weight gain than pasture mates that were not sprayed.

SUPPORTED BY Mississippi State Government

4.0694, BIOENVIRONMENTAL CONTROL OF COTTON BOLLWORMS
D.F. MARTIN, U.S. Dept. of Agriculture, Entomology Research Division, *Stoneville, Mississippi* 38776 (00ENTCO217250500)

OBJECTIVE: Develop ways of meeting cotton bollworm problems that will avoid or minimize the use of broad-spectrum, residue forming, and persistent insecticides which may pose immediate or long-range hazards to man, fish, wildlife, beneficial insects and other organisms in the environment.

APPROACH: Field research will be conducted on the ecology, population dynamics, and control of bollworms by bioenvironmental methods. Stress will be placed on practical bollworm control through research on biological, physical, and specific chemical methods in lieu of conventional insecticides.

PROGRESS. No Progress Reported this Period (New Project). Facilities still under construction.

SUPPORTED BY U.S. Dept. of Agriculture

4.0695, THE UPTAKE OF AND BIOLOGICAL RESPONSES TO AROCLORS IN CHANNEL CATFISH
J.G. ARMSTRONG, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Doses of Aroclors 1232, 1248, 1254, and 1260 will be individually administered daily by diet to groups of immature channel catfish. After 6 months, fish from each treatment will be examined for histopathology and for changes in blood serum constituents. Skeletal weights and thyroid activity will be estimated.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0696, SCREENING PESTICIDES FOR TERATOGENIC EFFECTS ON GAMBUSIA. TOXICITY OF PESTICIDES TO FRESHWATER FISHES
J.G. ARMSTRONG, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

The purpose of this work unit is to screen carbamates, fungicides, insect repellents, herbicides and polychloro biphenyls for possible teratogenic effects.

The mosquitofish, 'Gambusia affinis' will be used as a test animal. Groups of mosquitofish containing both male and female subjects will be fed formulations of the above compounds through their diet both alone and in combination. Whole, cleared

specimens of the resulting progeny will be examined for anomalies and histological sections will be evaluated.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0697, PESTICIDE EFFECTS ON FISH ENDOCRINE FUNCTIONS
B.F. GRANT, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Adult rainbow trout will be exposed to endrin or dieldrin in the diet for 6 months. On the day of autopsy, the fish will be forced to swim for 1 hr. The above constituents are to be studied. Serum Na, K, Ca, Mg, Cl, PO4, osmolality, NPN, total protein, electrophoretic analysis, cholesterol, creatinine, total amino acids, cortisol, lactate, glucose, and liver glycogen of the rainbow trout are to be studied.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0698, EFFECTS ON THE SPERMIATION RESPONSE OF GOLDFISH AFTER EXPOSURE TO SELECTED PESTICIDES
B.F. GRANT, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Adult male goldfish with developed testes will be injected with the spermiation gonadotrophin isolated by Sephadex G-100 gel filtration to induce the 24-hr spermiation response after having received six days exposure to various selected pesticides by bath in a metered continuous- flow system. A range of four half-log increments of dosage are given. The response in treated fish will be compared to the response of controls.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0699, NERVE IMPULSE TRANSMISSION CHARACTERISTICS OF ISOLATED FISH-NERVE PREPARATIONS PERFUSED WITH PHYSIOLOGICAL LEVELS OF SELECTED PESTICIDES
B.F. GRANT, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Pilot studies on intact and isolated nerve preparations are carried out using the Beckman Dynagraph II. Thresholds, action potentials, accommodation, inhibition, refractory periods, and other associated neurological phenomena in the presence of encountered levels of certain organochlorine toxicants in trout, catfish and tilapia in nature are estimated. Definitive work will follow as indicated by evaluation of preliminary studies.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0700, 72-HR THYROIDAL I125 UPTAKE IN IMMATURE CHANNEL CATFISH FOLLOWING EXPOSURE TO 5 DOSES OF SELECTED TOXICANTS (ABBREV.)
B.F. GRANT, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Immature channel catfish will be exposed to doses of toxicants such as insecticides and polychlorobiphenyl compounds with a continuous-flow dilutor. Survival conditions are kept optimal with respect to oxygen and waste accumulation. Organochlorine residues in the water and in the catfish are estimated when appropriate. After 30 days exposure, the fish are injected, 1 ul (0.01 uc)/gm, intraperitoneally with I125. The ability of the thyroid to fix radioiodine in 72 hr will be evaluated.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0701, SERUM ANALYSIS OF CUTTHROAT TROUT EXPOSED CHRONICALLY TO METHOXYCHLOR PESTICIDE EFFECTS ON FISH ENDOCRINE FUNCTIONS
F.B. GRANT, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

The serum of cutthroat trout will be studied during extended bath and feed treatments carried out at Jackson, Wyoming. The parameters to be measured are: Na, K, Ca, Mg, Cl, HCO3 (equilibrated with 5% CO2), NPN, urea, uric acid, creatinine, creatine, amino acids, cholesterol, total protein, and osmolality.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0702, COMPARISON OF METHODS USED TO MEASURE ESTERASE ACTIVITY. INTERACTIONS BETWEEN PESTICIDES ON FISH ENZYME SYSTEMS
J.W. HOGAN, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

This work unit will attempt to correlate results of esterase activity measurements obtained by two colorimetric methods and by a manometric method. Brain tissue from three species of fish, cutthroat trout (Salmo clarki Richardson), bluegill sunfish (Lepomis macrochirus Rafinesque), and channel catfish (Ictalurus punctatus Walbaum) will be analyzed for acetylcholinesterase levels. The entire brain will be removed from the fish, homogenized in deionized water, divided into aliquots, and diluted with the appropriate buffer. At least triplicate samples of each homogenate will be analyzed by all methods. Also, effects of storage by freezing will be studied. In vitro inhibition will be determined. Samples of homogenate will be incubated with various anticholinesterase agents and the resultant decrease in acetylcholinesterase activity will be measured. Brains removed from fish which have been exposed to various anticholinesterase agents will be analyzed to correlate in vivo inhibition. All results will be analyzed statistically to determine if there are any significant differences.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0703, SEASONAL CHANGES IN ESTERASE ACTIVITY IN FISH AND INVERTEBRATES. INTERACTIONS BETWEEN PESTICIDES ON FISH ENZYME SYSTEMS
J.W. HOGAN, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Samples of adult bluegill and at least one species of aquatic invertebrate will be collected at monthly intervals and assayed for acetylcholinesterase activity. The initial study will continue for at least one year. If statistically significant changes in esterase activity are found to be correlated with sampling date the study will be extended for a second year and may be expanded to include additional species.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0704, INTERACTIONS BETWEEN PESTICIDES AND FISH ENZYME SYSTEMS
J.W. HOGAN, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Different species of fish exhibit considerable variation in their susceptibility to organophosphate pesticide poisoning. It has been proposed that the effect of varying: (1) the chemical nature of the phpsphorus in the toxicant, i.e., dithionate or thionate, or, (2) the larger organic functional group should be examined in an attempt to explain species differences in susceptibility. The object of this work unit, therefore, will be to compare the toxicity of thionate and dithionate compounds with identical organic functional groups to species of fish having differing suspectibilities to anticholinesterase agents. Also, the effect (on toxicity) of varying the larger organic functional group will be determined. Acute and chronic toxicity, in vitro and in vivo brain acetylcholinesterase inhibition, and residue levels will be made to relate total alpha-amino acid nitrogen levels with each treatment and species. If significant correlation is observed individual amino acid analyses by GLC will be made.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish

4.0705, INTERACTIONS BETWEEN PESTICIDES AND FISH ENZYME SYSTEMS
J.W. HOGAN, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Use of fish brain acetylcholinesterase to assess the magnitute of environmental contamination resulting from organophosphorus pesticides is well documented. However, very little work has been directed toward the biochemical level with other members of the aquatic ecosystem. With this work unit we will attempt to characterize the esterase(s), present in an inver-

tebrate member of the aquatic environment. Crayfish 'Orconectes nais' was selected for this study due to its availability and importance as a source of food for certain game fish. Initial work will be concerned with methods used to obtain and maintain sufficient numbers of crayfish for further experimentation. Various tissues will be dissected from the crayfish and homogenized in an attempt to obtain an active enzyme preparation. Esterase characterization will be initiated as soon as the above work is completed. Characterization will include establishment of assay conditions such as optimum substrate and optimum substrate concentration. In vitro and in vivo esterase inhibition by organophosphorus pesticides will be examined.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0706, INFLUENCE OF PROTOZOAN ACTIVITY ON HALOGENATED HYDROCARBON RESIDUES - INTERACTION BETWEEN MICROORGANISMS AND PESTICIDES
B.T. JOHNSON, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Axenic cultures of a broad spectrum of free living freshwater protozoans will be studied in vitro with selected insecticides.

The parameters of this investigation will be as follows: 1. Effects on protozoan population of the insecticide. 2. Ability of the organism to utilize the pesticide as a sole carbon source. 3. Role of protozoans in degradation of halogenated hydrocarbon pesticides. 4. Study possible use of protozoans as bio-indicators of low concentrations of pesticides.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0707, THE EFFECT OF PESTICIDES ON PRIMARY PRODUCERS IN A FRESHWATER ECOSYSTEM (ABBREV.)
B.T. JOHNSON, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Axenic phytoplankton cultures are exposed to different insecticides and herbicides, alone and in combination at environmental concentrations. The polychlorinated biphenyl Aroclor series are studied also in conjunction with pesticides.

Effects on photosynthesis are measured by changes in C14-uptake using a liquid scintillation method. Biomass is determined by direct cell count, dry weight and ATP content. ATP is quantitatively determined utilizing the luciferin-luciferase enzyme system.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0708, THE INFLUENCES OF ENVIRONMENTAL CONDITIONS ON THE TOXICITY OF PESTICIDES
H.D. KENNEDY, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

The objective of the work is to investigate the effects of variations in bioassay conditions on the toxicity of pesticides to fish. Controlled variation of temperature, water quality, mass-volume relationships, and other factors will provide information concerning the influence of such factors on fish-pesticide relationships.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0709, THE SUSCEPTIBILITY OF VARIOUS LIFE STAGES OF FISH TO SOME COMMONLY USED PESTICIDES
H.D. KENNEDY, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

The objective of this work is to determine whether the uptake and activity (consequently the toxicity) of various pesticides differs among eggs, fry, various sizes of immature fish, and various sizes of mature fish. Representatives of the salmonids, centrarchids, and other families will be studied. The work will involve exposing the various life stages to the pesticides and determining relative toxicity indices.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0710, RELATIVE SUSCEPTIBILITIES OF FISH FAMILIES TO HERBICIDES
H.D. KENNEDY, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

The objective of the work is to establish a hierarchy, in terms of relative susceptibility to herbicides, for the families Salmonidae, Centrarchidae, Cyprinidae, Ictaluridae, and Percidae. Standard bioassay methods, under both static and continuous flow conditions, will be used to determine 24- and 96-hour TL50 values as indices of the susceptibility of the various taxonomic groups to representative herbicides.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0711, THE SUSCEPTIBILITY OF VARIOUS LIFE STAGES OF FRESHWATER FISHES TO THREE TOXICANTS
H.D. KENNEDY, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

This work attempts to evaluate differences in the uptake activity of various pesticides among various sizes of fish from egg to adult. Representatives of the salmonids, ictalurids, centrarchids, and other families will be studied. We will expose fish of particular lots or strains in size categories between 1-80 gm to antimycin, chlordane, and Abate 4-E in static or flow-through bioassay test systems to determine relative toxicity indices. Tests will be conducted under standard as well as altered conditions of temperature and water quality.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0712, RELATIVE SUSCEPTIBILITIES OF FISH FAMILIES TO HERBICIDES, FY 1971 (ABBREV.)
H.D. KENNEDY, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

This study attempts to evaluate phylogenetic differences in the susceptibility of the families Salmonidae, Cyprinidae, Ictaluridae, Centrarchidae, and Percidae to herbicides. Bioassay methods with standard and altered conditions of temperature and water quality under both static and flow-through systems will be used to determine 24 and 96-hr TL sub 50 values.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0713, SCREENING OF PESTICIDES AGAINST FRESHWATER FISHES, FY 1971
H.D. KENNEDY, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

This study is a continuing effort in deriving toxicities of various pesticides and combinations of pesticides to freshwater fishes. Static bioassays will yield TL sub 50 estimates and their confidence limits for 24, 48, 72, and 96-hr exposures under standard and altered conditions of temperature and water quality.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0714, INVESTIGATION OF STRESS-INDUCED MOBILIZATION OF INSECTICIDE RESIDUES - CHRONIC TOXICITY OF PESTICIDES TO FISH
K.J. MACEK, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

The objectives of the work are to determine if mobilization of insecticide residues, similar to that reported for higher vertebrates, does occur in fish during periods of stress, what the effects of such mobilization are, and what organs are involved in producing such effects. The work will involve feeding DDT and dieldrin to fingerling chinook salmon for approximately 200 days. After the exposure period, the fish will be subjected to several combinations of degrees of starvation and temperature fluctuations. Residue concentrations will be measured in whole fish and various organs and tissues to determine amounts accumulated

and metabolized during exposure, as well as the activity of such residues during stress.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0715, CHRONIC TOXICITY OF PESTICIDES TO FISH
K.J. MACEK, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

The objectives of the work are to determine the major source of DDT for salmonids existing in environments containing low levels of DDT in the water (pptr) and high levels in the food chain (ppm). Brook trout will be exposed to 5 pptr C14-DDT on a continuous flow basis, or to 3ppm C14-DDT in the feed on a daily basis, or to a combination of both treatments. Rates of accumulation and total amounts of DDT and its metabolites accumulated will be monitored for approximately 150 days. Organ distribution of DDT and its metabolites will be evaluated at the end of the study.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0716, CHRONIC EFFECTS OF DURSBAN O'I WARM-WATER FISH
K.J. MACEK, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Objective: To assess the chronic effects from contact exposure treatments of pesticides to warm-water fish in six one-tenth acre ponds at Columbia, Missouri. The fish will be exposed to various treatments of different concentrations. Samples of fish will be taken at predetermined times for chemical residue analysis, stomach samples, and for histopathological examination. Measurement of fish growth, survival, and reproduction will be made. Effects on other factors of the pond ecosystem: aquatic invertebrates, vegetation, plankton, and water quality will also be measured.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0717, EFFECTS OF PARATHION AND MALATHION ON WARM-WATER FISH PONDS
K.J. MACEK, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Objective: To assess the chronic effects of the insecticides malathion and parathion, alone and in combination, on the ecology of warm-water fish ponds. The ponds will be treated at approximately 28 day intervals with 0.5 lbs/acre of either or both of the insecticides. Chemical analysis will be performed on fish, water, mud and vegetation to measure insecticide residues. Effects on cholinesterase activity, histology, growth, feeding habits, and survival of green sunfish and channel catfish will be evaluated. Changes in structure of the invertebrate populations will be measured.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0718, UPTAKE, PERSISTENCE AND METABOLITES OF SEVIN BY CHANNEL CATFISH
K.J. MACEK, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

The objectives of this research are to determine the kinetics of uptake, metabolism and distribution of Sevin. Adult channel catfish are exposed to 14C Sevin either by continuous flow bath or daily in their feed. Two treatments levels in duplicate are used for bath and feed exposures. Rates of accumulation and total amounts of Sevin and it's metabolites are monitored at 3, 7, 14, 28, and 56 days. Chemical distribution and half life will be evaluated at the end of the study.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0719, CHRONIC TOXICITY OF PESTICIDES TO FRESHWATER FISHES
F.L. MAYER, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

This work is a continuing program for deriving toxicities of various pesticides against freshwater fishes in a flowing-water system. The exposure interval may be as brief as 96 hr, but mostly dosages are adjusted to allow the test to go 21-30 days or, in some instances, longer. Tests will be conducted under standard, as well as varied, conditions of temperature and water quality.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0720, POND ECOLOGY AND PRODUCTION AS AFFECTED BY SIMAZINE
F.L. MAYER, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Five quarter-acre ponds will be stocked with bluegills, 'Lepomis macrochirus', and treated with 0, 0.1, 0.3, 1.0, and 3.0 micrograms of Simazine per liter, respectively. The herbicide will be applied once per year (late March) for two years.

Serial samples will be taken to evaluate the following: fish growth and reproduction, pathology, residue levels (fish, invertebrates, plants, mud, and water), invertebrate population characteristics, plant pigment ratios, pond productivity, and water quality.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0721, EARLY SQUAMATION OF BLUEGILL (LEPOMIS MACROCHIRUS) AND FATHEAD MINNOWS (PIMEPHALES PROMELAS) EXPOSED TO AROCLORS
F.L. MAYER, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Patterns of early scale development will be studied on bluegill and fathead minnows receiving selected levels of the Aroclors 1242 and 1254. Chronic exposures will be given by bath. The fish samples will be sampled at pre-determined intervals, cleared with a 10% solution of concentrated hydrogen peroxide, stained with alizarin red, and their squamation compared with known patterns of development.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0722, FISH REPRODUCTION AS AFFECTED BY ORGANOCHLORINE INSECTICIDES
F.L. MAYER, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Brook trout will be exposed to methoxychlor or chlordane and bluegill to endrin or dieldrin through food for three months prior to spawning. Eggs will be taken, artificially fertilized and allowed to hatch. Egg and offspring mortality will be observed as well as growth rates of offspring. Whole adult fish, gonads, eggs, fry, and fingerlings will be taken periodically for insecticide residue analysis. Residues are to be correlated with hatching success and offspring mortality. Observations for teratogenic effects will be emphasized.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0723, CHRONIC TOXICITY OF PESTICIDES TO FISH
F.L. MAYER, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

The effect of Aroclors 1242 and 1254 on residual storage of DDT and dieldrin in bluegill, channel catfish, and rainbow trout will be determined. Fish will be treated via food or bath for four weeks. Liver detoxifying enzyme activities will be determined at selected intervals. Fish will be killed and analyzed for organochlorine residues at 0, 1, 3, 7, 14, and 28-day intervals.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0724, PESTICIDE EFFECTS ON FISH ENDOCRINE FUNCTIONS
P.M. MEHRLE, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Rainbow trout will be exposed to six months of DDT, dieldrin, and a combination of the two and subjected to 4 weeks of forced swimming. Seven samples will be taken at intervals of 6 hr., 24 hr., one wk., two wk., three wk., and four wk. Serum glucose, liver glycogen, and total serum amino acids will be deter-

mined to relate to estimations of total body lipid, total body nitrogen, and pesticide residues.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0725, PESTICIDE EFFECTS ON NITROGEN METABOLISM IN TELEOSTS
P.M. MEHRLE, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Parameters of nitrogen metabolism will be studied on fish receiving various doses of selected pesticides. Chronic and acute exposures of pesticides will be given by feeding and bath. Blood serum and liver preparations will be analyzed for specific amino acids, total protein, and collateral constituents related to lipid and carbohydrate metabolism. Biological activities of oxidative diaminases and amino tranferases are studied to elucidate mechanisms of induced dysfunction of intermediary nitrogen metabolism by selected pesticides. Chemical assays for amino acids will be carried out by GLC.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0726, PESTICIDE EFFECTS ON FISH ENDOCRINE FUNCTIONS
D.S. MINTZ, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Pilot studies of intact and isolated nerve preparations are to be carried out using the Beckman Dynagraph II, oscilloscope, and photographic recording equipment. Thresholds, action potentials, accommodation, inhibition, refractory periods, and other associated neurological phenomena will be studied. Changes of normal characteristics induced by neurological toxicants will be evaluated.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0727, MINERAL IMBALANCE IN BLUEGILLS EXPOSED TO MALATHION PESTICIDE-INDUCED MINERAL IMBALANCE IN FISH
E.T. OBORN, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

For acute concentrations of malathion - Sexed bluegills would be exposed to acute or near acute concentrations of malathion in either/or both bath water or from capsule ingestion. Sample harvest would follow 24 hours later.

For chronic concentrations of malathion - Sexed bluegills would be exposed to chronic concentrations of malathion for 30 days in either bath water and/or in the feed. Sample harvest would follow the 30-day exposure.

After both acute and chronic exposures to malathion, brain and blood would be incubated and measured for acetylcholine hydrolysis. Additional procedures followed and methods used would be in accordance with standard colorimetric analysis. Blood smears would be taken and blood coagulation time and hematocrit percent would be measured. After dissecting and proper processing, the tissues would be examined for iron, manganese, copper, zinc, phosphorus, calcium, and magnesium content.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0728, 2,4-D UPTAKE AND METABOLISM - METABOLISM OF PESTICIDES IN FISH
C.A. RODGERS, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Rainbow trout, channel catfish, and goldfish will be exposed to 0.1 and 1.0 ppm of 2,4-D butoxyethanolester under laboratory conditions. Carbon 14 labeled 2,4-D will be used as a tracer to determine the areas of storage of the herbicide. Two to four gram fish will be used for the test program and the following organs will be analyzed for 2,4-D: head, liver, kidney, and muscle. Blood will also be analyzed. In addition to individual parts, an autoradiograph of the whole body will be made.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0729, DDT AND DIELDRIN METABOLISM AND STORAGE BY CHINOOK SALMON UNDER LABORATORY CONDITIONS
C.A. RODGERS, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

This work will be a preliminary investigation involving DDT and dieldrin. Various organs and tissues of the fish will be analyzed for storage, buildup, and metabolism of the pesticides. This study will involve only the following organs: brain, heart, liver, kidney, blood, storage fat, lateral line muscle, body muscle, gill, stomach and hind gut. This study may indicate if it will be meaningful to select only a few primary target organs or tissues for future work with chlorinated hydrocarbons.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0730, UPTAKE AND METABOLISM BY FISH OF 2,4-D DIMETHYL AMINE SALT
C.A. RODGERS, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Rainbow trout, channel catfish, bluegills, and bass will be exposed to 1.0 and 5.0 ppm of the Dimethyl Amine Salt of 2,4 Dichlorophenoxyacetic acid under laboratory conditions. 14C ring labeled 2,4-D will be used as a tracer to determine total residue levels and distribution in organs. Exposure will be for three weeks with variable sampling intervals. Tissue extracts with high residue levels will be examined by TLC.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0731, DEVELOPMENT OF A STRAIN OF FISH RESISTANT TO AN ORGANOPHOSPHATE PROJECT - INTERACTION BETWEEN PESTICIDES AND FISH ENZYME SYSTEMS
C.A. RODGERS, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

The current decline in use of organochlorine insecticides, and the anticipated increase in use of organophosphates suggests that the latter may become an increasing problem in aquatic ecosystems. Therefore, organophosphate-resistant strains of fish would be a useful tool in fish management. Such fish could survive accidental contamination or be restocked in polluted waters which would not support non-resistant populations. Past research has shown that fish develop a resistance to organochlorine pesticides. In addition, limited evidence indicates that development of resistances to organophosphate pesticides may also be possible. To data, however, no research has been directed towards studying the biochemical basis for pesticide resistance in fish. The object of this work unit, therefore, will be two fold: 1) to develop a strain of fish having greater resistance to organophosphate pesticides, and 2) to study the biochemistry of this resistance.

An attempt to develop one or more resistant strains of fish will be made by exposing large numbers of mature individuals to acutely toxic levels LC sub 80 or LC sub 90 of selected organophosphates. Survivors will be allowed to reproduce and their offspring challenged with the same organophosphate pesticide. Resistance will be measured by percent survival in succeeding generations.

A limited study of the biochemical basis of pesticide resistance will be made by assaying various enzyme systems. For example, the esterase enzymes have been found to be important in invertebrate pesticide resistance and similar mechanisms may exist in fish as well.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0732, INTERACTION BETWEEN PESTICIDES AND FISH ENZYME SYSTEMS
C.A. RODGERS, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Previous research into pesticide resistance in fish has indicated that such resistance is genetically based. It seems possible, however, that pesticide resistance may also result thru the induc-

tion of one or more pesticide-degrading enzymes. The object of this work unit, therefore, will be to study the effect one or more pesticides has on the specific activity of selected enzymes.

Fish will be continuously exposed to sub-lethal concentrations of one or more pesticides, sampled at pre-determined intervals, and selected enzyme systems assayed. Enzyme induction will be determined thru comparison of the specific activity of a given enzyme over a long period.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0733, DETERMINATION OF ORGANOPHOSPHATES AND THEIR METABOLITES IN FISH BLOOD SERUM AND THEIR EFFECT ON CHOLINESTERASE ACTIVITY
C.A. RODGERS, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Use of cholinesterase in conjunction with other analytical chemical techniques to assess the degree of environmental pollution resulting from organophosphate insecticides is well recorded. However, limited research has been directed toward the use or organophosphate residues in blood to determine the amount of these chemicals present in aquatic ecosystems. To evaluate this aspect, fish will be exposed to one or more organophosphate insecticides. Blood samples will be taken periodically and attempts made to correlate residue levels of organophosphate pesticides in the blood with treatment levels and plasma cholinesterase activity.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0734, STUDIES ON THE UPTAKE AND TRANSLOCATION OF C14-LABELED DDT AND ALDRIN IN INVERTEBRATE POPULATIONS, FY 1970
H.O. SANDERS, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

The objective of this work is to study the role of invertebrate pesticide interaction in the aquatic ecosystem. Pesticide bio- amplification, using aquatic invertebrates in a simple food chain will be investigated. Invertebrate food chains will be established in the laboratory to investigate potential biopassage of labeled insecticides and herbicides from one ecological trophic level to another. Studies will include the following fish-food organisms: scud, glass chrimp, daphnia, fairy shrimp, crayfish, damselflies, mayflies, and mosquito larvae. When available, other organisms will be investigated. The study will also include the effects of continuous exposure of invertebrates to sublethal concentrations of pesticides, which may influence reproduction, life cycle stages, vigor, and resistance of the organisms.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0735, TOXICITY OF POLYCHLOROBIPHENYL (PCB) COMPOUNDS TO FRESHWATER INVERTEBRATES
H.O. SANDERS, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

We plan to obtain acute and long-term toxicity estimates for a variety of PCBs, singly or in combination with various organochlorine insecticides in several species of aquatic invertebrates. Invertebrates and PCB compounds are to be tested in static and continuous-flow bioassay systems in the laboratory. We will derive TL sub 50 estimates at various time intervals under static and continuous-flow conditions varying temperature, water quality, and animal age.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0736, STATIC BIOASSAY OF PESTICIDES USING FRESHWATER INVERTEBRATES TO OBTAIN PRELIMINARY ACUTE TOXICITY ESTIMATES (ABBREV.)
H.O. SANDERS, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

The objective of the work is to obtain preliminary acute toxicity estimates for a variety of pesticides and combinations of pesticides, tested against several species of aquatic invertebrates. Invertebrates and pesticides are tested in static bioassay systems in the laboratory. TL sub 50 estimates will involve various time intervals under static conditions with controlled variation of temperature, water quality, and animal age.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0737, CONTINUOUS-FLOW BIOASSAY OF PESTICIDES TO EVALUATE THE ACUTE AND CHRONIC EFFECTS OF PESTICIDES TO FRESHWATER INVERTEBRATES (ABBREV.)
H.O. SANDERS, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

The proposed research will evaluate the acute and chronic effects of pesticides and combinations of pesticides on aquatic invertebrates exposed in continuous-flow systems. We will derive estimates of TL sub 50's for various periods of exposure under standard conditions of temperature and water quality. Particular emphasis is to be placed on sensitivity of different life cycle stages, molting, and emergence success.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0738, RESPIRATION RATES OF FISH-FOOD INVERTEBRATES EXPOSED TO PESTICIDES
H.O. SANDERS, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Invertebrates are to be exposed to varying concentrations of several pesticides for short durations. Oxygen uptake and carbon dioxide liberation will be estimated with a Warburg apparatus fitted with macro-vessels. All major pesticide groups such as organochlorines, organophosphates, and carbamates will be investigated.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0739, UPTAKE, DEGRADATION, AND RETENTION OF C14-METHOXYCHLOR IN INVERTEBRATE POPULATIONS
H.O. SANDERS, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Invertebrate members in fish food chains will be exposed to C14- methoxychlor in static and continuous-flow systems and we will evaluate the following parameters: rates of uptake from the water and through the diet, localization of methoxychlor in organs and tissues, degradation of the compound, and residue retention. Tests are to include 8 species of freshwater invertebrates distributed among 4 orders of aquatic insects, Diptera, Plecoptera, Ephemeroptera, and Megaloptera, and two orders of crustacea, Eubranchiopoda and Decapoda. Scintillation radiometry and autoradiograms will provide information on rates of accumulation, retention, and degradation of C14-methoxychlor.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0740, METHOXYCHLOR-CAUSED EFFECTS ON CUTTHROAT TROUT PHYSIOLOGY - CHRONIC TOXICITY OF INSECTICIDES TO COLD-WATER FISH
D. SWEDBERG, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

The purpose of the work is to measure chronic effects from the exposure of cutthroat trout to methoxychlor at Jackson, Wyoming. Fish will be divided into lots and sub-lots and held in pens in hatchery raceways. Some groups will be given no methoxychlor, some given methoxychlor in feed at two levels, and some given methoxychlor baths at two levels. Samples will be taken according to a pre-arranged schedule, and fish will be examined and measured for growth, pathology, incidence of disease, blood chemistry, insecticide residues, mortality, reproduction, and quality of offspring. Comparisons among lots will be made to assess effects of methoxychlor.

4. PESTICIDES

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0741, MULTIPLE EXPOSURES OF ABATE TO BLUEGILL, LEPOMIS MACROCHIRUS, AND INVERTEBRATES IN WARM-WATER PONDS
D.F. WALSH, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Four ponds will receive three treatments at 28-day intervals. Duplicate concentrations of 0.1 lb/acre and 1.0 lb/acre will be applied. Two additional ponds will serve as untreated controls. The first treatment will be applied April 13.

Samples will be taken at regular intervals to evaluate the following: brain cholinesterase activity, gonadosomatic index, vitellogenesis, pathology, residue levels (fish, selected components of habitat, and fish food organisms), structure and composition of invertebrate populations, and water quality.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0742, EFFECTS OF INSECTICIDES ON ACTIVITY OF SOIL INHABITING INSECTS
M.L. FAIRCHILD, Univ. of Missouri, Agricultural Experiment Sta., *Columbia, Missouri* 65201 (MO00572)

OBJECTIVE: Evaluate effects of various insecticides and rates and methods of application on the activity of soil inhabiting insects in corn fields at certain intervals of time following applications; determine possible lateral or vertical movement of insecticides in soil by measuring biological activity; study the effect of soil type, moisture content, and organic content on insecticidal activity through bioassay.

APPROACH: Soil samples will be taken from numerous soil treatments in corn fields, and the insect activity will be examined. Samples will be taken at various locations in the soil and at several intervals following treatment. A screening-flotation technique will be utilized to remove insects from soil and species and numbers will be recorded.

PROGRESS: Plots at Columbia, McBaine, and McCredie and broadcast- treated with six different insecticides. An infiltrometer was used at two locations near McBaine and one location near Columbia to simulate rainfall on the plots. Soil and water run-off samples were collected from each plot for analysis. The plots at McCredie were used to collect water run-off from natural rainfall. Soil samples were bioassayed and the water run-off samples were analyzed by gas chromatography. Other plots near Rock Port and Tarkio were used to compare insecticide sprays, granular formulations, band width, incorporation methods, layby treatments and dates of application. Soil samples were collected at 14- day intervals. The samples were three inches in depth and three inches in diameter taken from the center of each row. Homogenized samples from each entry were bioassayed. A total of 247 samples were tested. Methods of mass rearing of the black cutworm are being developed for bioassay of soil insecticide activity. Methods of eliminating or reducing incidence of disease and cannibalism are being studied. Studies on effect of temperature, humidity, diets, and various rearing containers on larval growth, pupation, and egg production are underway. Excellent results have been achieved through the third generation.

SUPPORTED BY U.S. Dept. of Agriculture

4.0743, EFFECT OF PESTICIDES ON INSECT PARASITES AND PREDATORS
F.R. LAWSON, Univ. of Missouri, U.S.D.A. Entomology Res. Div., *Columbia, Missouri* 65201 (00ENTJ0206260100)

OBJECTIVE: Determine the toxicity of candidate insecticides to the predators and parasites of insects and spider mites.

APPROACH: Colonies of representative species of insect predators and parasitic and predaceous mites will be set up and maintained in the laboratory as stock cultures. New chemicals that show promise as insecticides will be tested against these species by standardized procedures.

PROGRESS: No progress reported this period (Active Project).

SUPPORTED BY U.S. Dept. of Agriculture

4.0744, PESTICIDE-WILDLIFE RELATIONSHIPS - REPRODUCTION, GROWTH, AND PHYSIOLOGY OF DEER FED DIELDRIN CONTAMINATED DIETS
L.J. KORSCHGEN, State Dept. of Conserv., *Jefferson City, Missouri* 65102

Procedures supplement and continue progress of this study during 1964-1968 when continuing phases of this study were conducted. Field aspects of the investigation were completed during fiscal year 1968- 69, with sacrifice of the experimental herd of treated and control animals. Laboratory analyses for residues in brain, liver, and muscle tissues were performed by WARF Institute, Inc., Madison, Wisconsin, for 140 animals which survived to termination date or were lost during 4 years of herd maintenance and 3 years of production.

Objectives and procedures for the year are to compile, analyze, and interpret data from the five-year investigation and prepare a final report of results.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0745, A STUDY OF THE DEGRADATION RATE OF ALDRIN
L.J. KORSCHGEN, State Dept. of Conserv., *Jefferson City, Missouri* 65102

Procedures and objectives of this investigation continue progress of a phase of study initiated in 1964-65, otherwise titled 'Soil- Food Chain-Pesticide Wildlife Relationships', primary objectives of which were fulfilled during fiscal year 1968-69. The objective of this phase of study is to obtain residue data from soil and earthworms during the fifth year following five annual applications of aldrin at recommended rates for pest control with no further treatment. Increased knowledge relative to the degradation rate of aldrin and its metabolite, dieldrin, will be gained from the investigation.

Procedures: (1) Collect two each of pooled soil and earthworm samples during October 1969 and April 1970. (2) Submit samples to WARF Institute, Inc . Madison, Wisconsin, for residue analyses. (3) Compile and compare residue results with previously accumulated data to show trend in rate of aldrin degradation, and prepare annual report.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0746, DEGRADATION AND PERSISTENCE OF ALDRIN
L.J. KORSCHGEN, State Dept. of Conserv., *Jefferson City, Missouri* 65102

Previous work on this investigation, initiated in 1965, has involved collection of soils and earthworms from one field after five annual aldrin treatments and no further applications. Results from spring and fall sampling through spring 1970 provide data for year to year comparisons of aldrin and dieldrin residues and a basis for determining potential hazards to wildlife from the utilization of foods obtained from pesticide-treated habitat.

The objective of this segment of work is to compile data collected semi-annually for 5 years to show the rate of aldrin disappearance, and to prepare a final report.

Procedures: 1. Assemble aldrin-dieldrin residue data derived from analyses by WARF Institute, Inc., Madison, Wisconsin, of 22 pooled samples each of soils and earthworms collected from spring 1965 through spring 1970. 2. Analyze and interpret data to show rate of aldrin degradation and persistence. 3. Prepare final technical report for publication.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0747, EFFECTS OF A PESTICIDE ON REPRODUCTION OF CONFINED COTTONTAILS
K.C. SADLER, State Dept. of Conserv., *Jefferson City, Missouri* 65102

The purpose of this investigation is to test the effects of dieldrin, administered at 0.5 and 2 pounds per acre, on reproduction of confined cottontails.

This is the fourth year of a five-year study supported by a grant from the U.S. Bureau of Sport Fisheries and Wildlife and is a cooperative project involving Clinton H. Conaway, Professor of Zoology, University of Missouri; W. Reid Goforth, Biologist, Bureau of Sport Fisheries and Wildlife, and the writer; with John Elliston as research assistant.

Experiments are being carried out in pens on the University of Missouri's Ashland Wildlife Area, Ashland, Missouri. Reproductive performance of cottontails held under semi-wild conditions are being analyzed after exposure to dieldrin for one or more years. Of special interest will be the sub-lethal effects of dieldrin on timing of the onset of reproduction, ovulation rates and embryonic mortality under the two experimental pesticide levels and the control population.

Tissue analyses will be made to note differences in pesticide levels detectible in rabbits under different applications.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0748, MAMMALS, FISHES AND BIRDS OF MONTANA

C.J. BROWN, Montana State University, Agricultural Experiment Sta., *Bozeman, Montana* 59715 (MONB00400)

OBJECTIVE: Secure basic biological information on mammals, fishes, and birds of Montana which can be used as a basis for the management of these groups. Since the management of these animals is the responsibility of the State Fish and Game Department, it is desirable that research be conducted in cooperation with that agency.

APPROACH: Standard procedures will be followed to study natural populations of fish, birds, and game, including habitat, competition, food habits, reproduction, growth and losses. Man-made effects on environment, including pollution, dam construction, pesticides, hunting, etc. will be examined.

PROGRESS: C.J.D. Brown-Fishes: I. Projects completed during past year: A. Two fish parasite studies; (1) Migration routes and pathological effects of larval trematodes, (2) Life cycle and sub-lethal effects of a heart-infecting trematode; B. Movement behavior of cutthroat trout; C. Acoustical phenomena in relation to cutthroat trout movement; D. Serological study of cutthroat trout; E. Distribution and ecology of trout fingerlings; F. Life history of the mountain sucker; II. Projects continuing during next year: A. Movement behavior of cutthroat trout; B. Stream limnological studies; C. Parasitic fauna of cutthroat trout; D. Movement behavior of mountain whitefish; E. Life history of river-dwelling lake sturgeon; F. Montana Fishes (Bulletin). D.C. Quimby-Mammals: (1) Effects of chemical control of sagebrush on small mammal populations*, (2) Effects of chemical control of sagebrush on pronghorn antelope populations*, (3) Mule deer-whitetail deer range relations in Snowy Mts.*, (4) Relationship of mule deer to summer range and livestock in the Pryor Mts.*, (5) Elk-livestock relations in Crow Creek Drainage (terminated 9/30/68), (6) Food habits, range-use, movements, and relationship of antelope to livestock SE Montana*, (7) Populations, range-use, and distribution of moose in the upper Centennial Valley SW Montana*. Robert L. Eng: A. Small bird population with respect to sage brush manipulation - continuation (post- spray phase). B. Bluegrouse behavior and territorial requirements - continuation. C. Juvenile sage grouse food habits - continuation.

SUPPORTED BY Montana State Government

4.0749, EFFECTS OF CHEMICAL SAGEBRUSH CONTROL ON MULE DEER IN THE MISSOURI RIVER BREAKS, MONTANA

E.F. SCHLATTERER, State Fish & Game Department, *Helena, Montana* 59601

Objectives: To determine the effects of chemical sagebrush control on mule deer habitat in the Missouri Breaks.

Procedures: 1. Attach radio transmitters on two or more deer and mark others with collars that regularly use the study area. Weekly observations will be made of these deer to determine key areas of seasonal use within the study area. Particular attention will be given to the late winter and early spring period when more intensive use of sagebrush has been previously noted 2. Sample the vegetation on treatment and control areas prior to and after sagebrush removal. 3. Systematically travel vehicle observation routes and record numbers and distribution of mule deer observed on various vegetation types and physiographic sites. 4. Establish permanent plots on which deer pellet group and cow chip counts will be made. 5. Establish and read forage utilization, production, and condition trend sample units for important forage species on various vegetational communities on and adjacent to treatment and control pastures.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0750, ORGANIC PHOSPHATE SYSTEMIC INSECTICIDES AND EMBRYONIC SURVIVAL AND DEVELOPMENT IN THE BOVINE

R.A. BELLOWS, U.S. Dept. of Agriculture, Animal Science Research Div., *Miles City, Montana* 59301 (033003912 1327)

OBJECTIVE: Determine whether either of two systemic organic phosphate insecticides administered to beef cows at two levels have deleterious effects on embryo development.

APPROACH: Virgin beef heifers with no history of recent organic phosphate treatment were maintained in drylot at nutritional levels recommended for optimum reproduction. After 60 days they were bred and assigned to treatments of two levels (recommended and minimum toxic) of Rueline or Co-Ral administered from 10 to 125 days of pregnancy. At calving time calves were examined for normality. Abnormal calves or calves dying early in life were studied by detailed post mortem examination. After the results are summarized a second experimental phase will be designed if necessary to elucidate the mode of action of the pesticides.

PROGRESS: Treatment of beef heifers with systemic, organo- phosphate insecticides (Ruelene or Co-Ral) during early stages of pregnancy failed to indicate deleterious effects on embryo development. No effect was noted on conception rate, number of services per conception or embryo survival. Data are presently being summarized in preparation for publication

SUPPORTED BY U.S. Dept. of Agriculture

4.0751, ORGANIC PHOSPHATE SYSTEMIC INSECTICIDES AND EMBRYONIC SURVIVAL AND DEVELOPMENT IN THE BOVINE

R.A. BELLOWS, U.S. Dept. of Agriculture, Range Livestock Station, *Miles City, Montana* 59301 (033003932 1327)

OBJECTIVE: Completed.

APPROACH: Comp leted.

PROGRESS: Treatment of beef heifers with systemic, organo- phosphate insecticides (Ruelene or Co-Ral) during early stages of pregnancy through m-Linear research at Miles City, Montana failed to indicate deleterious effects on embryo development. No effect was noted on conception rate, number of services per conception or embryo survival.

SUPPORTED BY U.S. Dept. of Agriculture

4.0752, THE FATE AND EFFECTS OF PESTICIDES IN THE AQUATIC ENVIRONMENT OF THE FLATHEAD LAKE DRAINAGE AREA

A.R. GAUFIN, Univ. of Montana, Graduate School, *Missoula, Montana* 59801

Samples of water, mud, plankton, higher aquatic plants, fish, bird eggs, and fat from birds as pheasant, and deer will be analyzed with a gas chromatograph for residual pesticides. The procedures to be used for the chromatographic analysis will necessarily have to be varied with the type of sample, but analyses performed on deer fat samples during the last year are indicative of methods which will be used. The analyses were performed using a model 27-700 chromatograph manufactured by the Jarrell-Ash Co. The chromatograph is equipped with an electron capture detector employing tritium coated foil as an electron source. The 46' x 1/4' pyrex column was packed with 1.5% Se- 30 on Chromasorb G SMCS, A/W, 70/80 mesh. The carrier gas, nitrogen, was maintained at 28 lbs. per sq. inch. The column temperature was 185 degrees C.; the detector temperature was 190 degrees C.; the injector temperature was 185 degrees C.

The extraction procedure was the same for each sample. Fifteen grams of the wet tissue were dessicated for 36 hours at 60

degrees C., then transferred to a mortar and pestle and homogenized. A 1.10 gram sample of the homogenized material was extracted in a 10 milliliter tissue grinder four times, using 5 milliliters of nano grade hexane for each extraction. The 20 milliliters of extract were filtered, the filtrate evaporated to 5 milliliters and transferred to a tightly capped serum vial for analysis. For the analysis 15 to 30 microlite aliquots were injected into the chromatograph.

The number of samples which will be analyzed will be dependent on the personnel and time available, but enough samples will be tested to be significant. The samples will be taken from various areas in the Flathead Lake-Ninepipe Reservoir drainage system and pesticide levels will be correlated with such data as sources of contamination, plankton productivity, nesting populations of ospreys, fish distribution and kills. Inasmuch as a project is being conducted at the Biological Station dealing with plankton productivity and water quality in the lake, and the Fish and Game Department is conducting a study of fish populations in the lake this proposed project will be coordinated with these other studies.

4.0753, CO-RAL, RUELINE AND EMBRYONIC SURVIVAL AND DEVELOPMENT IN THE BOVINE
R.D. HUMPHREY, Fort Robinson Beef Cattle Sta., *Fort Robinson, Nebraska* 69339 (03300392213?8)

OBJECTIVE: Completed.

APPROACH: Completed.

PROGRESS: Related work at Crawford, Nebraska suggested treatment on day 40 of gestation had a teratogenic effect on the embryo. The effect resulted in a missing or constricted segment of the colon of the newborn calf. However, subsequent studies involving 99 cows treated during the suggested 'critical period' including days 35 to 46 of gestation failed to confirm the initial finding.

SUPPORTED BY U.S. Dept. of Agriculture

4.0754, THE RELATIONSHIP BETWEEN THE USE OF AGRICULTURAL CHLORINATED HYDROCARBONS AND THEIR RESIDUES IN CHANNEL CATFISH
N. STUCKY, State Game & Parks Commission, *Lincoln, Nebraska* 68509

Objectives: 1. To complete and publish the manuscript begun in Segment 15. 2. To complete statistical analysis of data collected from six drainages in Nebraska and prepare for publication those aspects of the study which warrant reporting in technical journals.

Procedures: 1. Complete and publish the manuscript begun in Segment 15. This will be a descriptive paper expressing the results obtained from analyzing channel catfish fat and blood samples for DDT and dieldrin residues. Samples were collected from 18 major drainages in Nebraska. The manuscript will be submitted for publication in 'Pesticides Monitoring Journal.' 2. Compile data obtained from six major drainages and analyze statistically the relationship between pesticide residue detected in fish and various physical parameters. The established parameters are: rainfall, land use, drainage basin size, and calculated amount of pesticides applied during the period from 1960 to 1964. Preparation of a manuscript for publication is conditional pending the outcome of the statistical analyses.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0755, PESTICIDE DATA - PHEASANT
C.W. WOLFE, State Game & Parks Commission, *Lincoln, Nebraska* 68509

Objectives: To complete chemical analysis of pheasant eggs, and statistical programming and analysis of pesticide data collected in conjunction with previous job segments.

Procedures: Pheasant eggs collected on the Harvard and Clay Center Study Areas will be analyzed by electron-capture chromatography. This data and other pesticide data will be combined for statistical analysis. Programming and analysis will be conducted in conjuncton with the Statistical Laboratory, University of Nebraska. Emphasis will be placed on: 1. Residue levels in eggs, and 2. Effects of pesticides on reproduction. Results will be submitted for publication in a technical journal.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0756, EFFECTS OF ETHYL PARATHION ON PHEASANTS
C.W. WOLFE, State Game & Parks Commission, *Lincoln, Nebraska* 68509

Objectives: To determine the effect of ethyl parathion on the ring-necked pheasant.

Procedures: 1. Work will be directed toward completion of tabulation and analysis of blood and brain cholinesterase levels. 2. A complete review of effects of stress on cholinesterase levels will be made. 3. Data will be incorporated into two technical publications; one will be prepared for entomological interests, the other for wildlife interests.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0757, FIELD AND LABORATORY INVESTIGATIONS OF INSECTICIDES
A.F. HAGEN, Univ. of Nebraska, Agricultural Experiment Sta., *Lincoln, Nebraska* 68508 (NEB-17-016)

OBJECTIVE: Evaluate and test new insecticides, formulating application rates and methods for control of injurious insects and to investigate possible cases of resistance to insecticides.

APPROACH: Suspected cases of insecticidal resistance in the field will be investigated by removing and treating cultures under controlled conditions in the laboratory.

PROGRESS: Toxicity of ethyl parathion to juvenile pheasants was studied. No direct mortality of pheasants was observed. Insect populations were reduced. Sevin continued to give good control of western bear cutworm. Biological factors (parasites, predators and diseases) also aid in population reduction. Malathion applied to a wide area apparently has no long range effects on insects other than rootworms. Overall rootworm populations were reduced 50% in treated area. Adult populations were reduced 90%. TIBA alone and in combination with the systemic insecticides Di-Syston and metasystox-R increased soybean yields significantly. Yields from insecticide treatments alone were not significantly different from the check. Twenty-two insecticide treatments were tested against the pale western cutworm in wheat (13 chemicals at various rates and formulations). All were better than the check. Five gave excellent control; the rest were mediocre. All chemicals tested should leave no residue at harvest. Four chemicals were tested for residue on alfalfa. One chemical was tested for residue in the soil and one was tested for residue as a seed treatment of field beans. The results of these tests are not known at this time.

SUPPORTED BY U.S. Dept. of Agriculture

4.0758, METABOLIC INTERRELATIONSHIPS AFFECTING NUTRIENT ENERGY REQUIREMENTS OF HUMANS
C. KIES, Univ. of Nebraska, Agricultural Experiment Sta., *Lincoln, Nebraska* 68508 (NEB-91-007)

OBJECTIVE: Determine interrelationships among the essential amino acids which affect ideal amino acid proportionality patterns for humans; determine qualitative, quantitative dietary fat-protein interrelationships as factors affecting human blood lipid patterns; investigate nutrient interrelationships affecting the adequacy of non- animal and unconventional proteins to meet protein needs of humans; and, study the possible influences of naturally occurring and incidental anti-nutrients on vitamin requirements, such as herbicide residues on pantothenic acid requirements.

APPROACH: The characteristic quantitative pattern of dietary amino acids consistant with optimum protein nutrition in adult humans will be determined. The influence of qualitative and quantitative alterations in nitrogen intake on the blood lipid fractions and the fatty acid components of these fractions will be studied. The effects of altering nitrogenous components of the diet and caloric intake on the utilization of non-conventional proteins

as well as the effect of herbicide residues on the metabolism of pantothenic acid will be determined.

PROGRESS: Determine the first limiting amino acid in rye flour for maintenance of protein nutritive in human adults was the objective of the first study. Mean nitrogen balance of 10 adult men fed 4.0 g N rye flour diets supplemented with L-methionine, L-tryptophan, L-lysine, a combination of all three amino acids, or no supplement were -1.28, - 1.21, -1.08, -0.58 and -0.58 g N/day, respectively, indicating lysine as being the first limiting amino acid in rye. The objective of a second study was to study lysine-tryptophan interrelationships affecting protein requirements of adult men. Using a semi-synthetic, controlled diet, 9 men were fed low, medium and high levels of tryptophan and of lysine in all possible combinations (low L low T, medium L low T, etc.). The feeding phase of this study has been completed.

SUPPORTED BY U.S. Dept. of Agriculture

4.0759, STUDY OF INJURIOUS INSECTS ON FORAGE CROPS

W.H. ARNETT, Univ. of Nevada, Agricultural Experiment Sta., *Reno, Nevada* 89507 (NEV00138)

OBJECTIVE: Study biology and behavior of insect pests affecting forage crops and develop the best control means utilizing chemical, cultural and biological methods. Relate pest populations with damage produced to forage crops and collect residue data on chemicals used for forage insect control.

APPROACH: Greenhouse, laboratory and field studies will be designed and conducted to obtain information and biology and behavior of both pest and beneficial insects on forage crops. Chemicals and cultural practices will be evaluated as to their impact on both pest and beneficial insects and pest population levels will be correlated with both qualitative and quantitative aspects of damages. Samples will be collect in order to determine persistence and magnitude of insecticide chemicals in forage crops.

PROGRESS: Applications of various insecticides as early spring treatments against the adult alfalfa weevil indicated that only RCS-2123 gave a high degree of control. Comparative applications of Furadan, carbaryl and methyl parathion indicated that Furadan gave as good or slightly better control of alfalfa weevil than either of the presently recommended materials. Populations of pea aphids remained well below economic levels following use of Furadan but increased to economic levels following carbaryl treatments. Timing treatments comparing Furadan, 8 and 16 oz. per acre with the same rates of methyl parathion indicated that both rates of Furadan gave effective larvae control up to 28 days whereas with methyl parathion control was obtained for 10-14 days. Similar weevil larvae control was obtained when two formulations of Furadan (75WP and 4 lb. F) were compared. Comparisons of Furadan and Guthion indicated that similar dosages rated gave equivalent degree of weevil larvae control over a 10-14 day period. Experiment materials tested on small plots which gave excellent weevil larvae control included: SD 1698, 8 oz. per acre; SD17250, 8 oz.; VC506, 16 oz.; Bayer 68138, 8 oz.; Bayer 93820, 12 oz.; Ortho 11775, 16 oz.; Ortho 11776, 16 oz.; UC 34096, 32 oz. Data on the effect of pesticides on beneficial (predators) insects were obtained from all field plots.

SUPPORTED BY U.S. Dept. of Agriculture

4.0760, BEE INVESTIGATIONS

B.B. PEPPER, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00406)

OBJECTIVE: Varietal preference of solitary, bumblebees and honey bees when working blueberry bloom. Attractiveness of cranberry bloom to pollinating insects as affected by climatic factors and plant competition. Management of bees to obtain known crosses or selfpollination in holly, asparagus and blueberries.

APPROACH: Field observations to determine attractiveness of bloom to various pollinating insects. Blossom and fruit counts to determine degree of pollination in plantings. Cage tests with honey bee pollinators. Seed counts, measurement of berry size and weight of self and cross pollinated bloom.

PROGRESS: As a result of grower concern, bee activity on holly was observed to compare dimethoate-treated with untreated or lindane-treated trees. Although bloom was heavy and sticky with nectar, dimethoate- treated trees had almost no bees working while activity appeared normal where other insecticides or no sprays were used. Controlled experiments on bee repellency by dimethoate on holly are being planned for 1970. Brood food was collected from colonies in the New Jersey regions of high and low European foulbrood incidence. Brood food pH ranged from 4.1 to 5.2 with no apparent correlation with regions. Brood rearing ceased in caged colonies so no brood food could be collected from them. Royal jelly and brood food samples were frozen for bacteriological examination. An automatic pollen trap was perfected for recording the time of day pollen pellets are collected by bees. It consists of a sticky revolving cylinder which holds pollen loads scraped from the legs of bees entering the hive through a grid above the cylinder. Pollen collections were made by both automatic and manual traps during cranberry bloom to study the time of day bees concentrate on cranberry bloom and to discover variations among hives in the percentages of cranberry pollen collected.

4.0761, WEED CONTROL IN ORNAMENTAL NURSERY STOCK

W.V. WELKER, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00150)

OBJECTIVE: Evaluate herbicides for the control of weeds in nursery stock, various methods of application of herbicides to nursery stock raised in containers, and investigate the long term effects of repeat applications of herbicides upon growth and quality of nursery stock.

APPROACH: Studies will be conducted in the greenhouse and field. Acceptable statistical designs shall be used in all cases. All data will be subjected to statistical analyses and interpretation. Data will be collected on the effect of the herbicides on growth and vigor of the crop and selectivity of the weeds. The effects of repeat application of the same herbicide on the same plot shall be measured over a number of years. Greenhouse screening of new chemicals for use on nursery stock shall be conducted periodically as promising new chemicals are made available.

PROGRESS: A greenhouse screening program to evaluate tolerance of Pyracantha and Juniper to various herbicides was initiated in the summer of 1969. Seventeen herbicides at various rates were tested. The herbicides were applied to the soil to one group and the foliage of another while the soil was covered. These are still being evaluated. Injury symptoms are being noted and photographed. In a field study including Japanese holly and Taxus, the same herbicides were applied for the third year. All treatments have been applied in the fall each year. Satisfactory weed control has been obtained with dichlobenil, simazine, terbacil, and linuron through the first of July. Sinbar gave satisfactory weed control through the entire season. Slight injury symptoms were noted for the first time on those plants receiving the terbacil treatment. No other injury was noted.

4.0762, INCREASED BODY METABOLISM AND EXCRETION RATE OF PESTICIDE FROM DAIRY COWS

D.D. MILLER, New Mexico State University, Agricultural Experiment Sta., *Las Cruces, New Mexico* 88070 (NM00151)

OBJECTIVE: Determine the effect of various levels of body metabolism on the rate of excretion of pesticide through the milk by contaminated cows.

APPROACH: Sixteen bred heifers will be contaminated with DDT so that after calving they will secrete between 5 and 10 ppm in their milk. Four will be fed a normal ration; four a normal ration plus thyroprotein; four a two-thirds normal ration; and four a two-thirds normal ration plus thyroprotein. The milk will be tested weekly until it is free of pesticide. Change in body weight and total milk production of all animals will be recorded.

PROGRESS: Studies were continued on DDT contaminated cows secreting milk containing between 7 and 12 ppm of pesticide on a milk fat basis. Previously it had been shown that cows receiving a low- energy diet for 42 days would have the time required for the pesticide level in their milk to reach 1.25 ppm shortened by approximately 75 days. Work this past year has

shown that if the cows can be obtained in the expulsion of DDT. If this ketotic condition is implemented during the first 3 months of the cow's lactation, no appreciable reduction in the cow's total milk production will occur. Even though this is an appreciable reduction in time of removal of DDT, it still requires approximately 115 days to reduce the pesticide level from ca. 10 ppm to 1.25 ppm on a milk fat basis.

SUPPORTED BY U.S. Dept. of Agriculture

4.0763, TOXICITY AND CARCINOGENICITY OF DIPHENYLAMINE TO MICE

L. GOLBERG, Union College & University, School of Medicine, *Albany, New York* 12208 (HC-72(C))

OBJECTIVE: Determine the toxicity of diphenylamine administered orally to mice during a life span of 80 weeks.

APPROACH: A total of 600 male and 600 female weanling albino mice will be fed diets containing diphenylamine at three concentrations along with a control group which shall be fed a diphenylamine-free diet. Records of health and condition of the mice will be kept throughout the test. Analyses of various blood samples and examination of the major organs of autopsied animals during the course of the feeding tests and at their conclusion will furnish data to be included in a final evaluation and recommendation concerning toxicity of diphenylamine for its use as a scald inhibitor on apples.

PROGRESS: Feeding tests for determining toxicity of diphenylamine to mice were completed in June 1970. Final reports on all sacrificed animals and a summary of the findings will be forthcoming within a few months. The clinical state of the mice remained good throughout the tests with low mortality and well maintained body weights. The 20 mice sacrificed from each of the 4 feeding levels at the end of one year of the experiment showed no gross pathological changes in any of the mice attributable to the administration of diphenylamine. The detailed histopathological examinations on at least 16 different tissue areas showed slight variations between mice fed on different levels of diphenylamine. The significance, if any, of these differences must await a final evaluation of all data obtained. A suggestion for recommended level of diphenylamine on apples that would be considered safe is expected.

SUPPORTED BY U.S. Dept. of Agriculture

4.0764, SELECTIVE TOXICITY - AN APPROACH TO ENVIRONMENTAL HEALTH

T. GESSNER, State University of New York, School of Pharmacy, *Buffalo, New York* 14214

This will be a study of the comparative detoxication of various organic sulfur compounds, aimed at yielding information on the similarities and differences between mammalian and insect detoxication mechanisms. Compounds will be synthesized, where necessary with radioactive isotopes, and their metabolic fate determined in both mammals and insects of several species. The possible role of the above compounds as inhibitors of detoxicative processes will be studied by noting their effect on the biotransformation of several aromatic compounds whose normal metabolic fate is well documented. Efforts will be made to determine the sites of detoxication in insects. The knowledge resulting from this study should aid in the development of selective chemical pest control, and hence help in reducing the environmental health hazard resulting from the economically essential widespread use of pesticides.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.0765, CONTROL OF APPLE INSECT PESTS WITH REDUCED SPRAY SCHEDULES

R.W. DEAN, New York State Agric. Sta., *Geneva, New York* 14456 (NYG00549)

OBJECTIVE: Determine if the generalized orchard spray program now in use is necessary under present conditions of low pest populations existing in commercial orchards, or if it can be reduced or modified so as to lower production costs, lessen health hazards from exposure to insecticides and their residues, and reduce the rate of accumulation of persistent chemicals in the soil, all without permitting increases in pest damage.

APPROACH: Commercial orchard blocks, in which insect pests are now under good control, will be sprayed according to schedules which omit applications at less critical periods, or which depend upon coverage resulting from spray drift from adjoining treated rows. The most effective insecticides will be employed and applied by means of air- blast equipment, similar to that used in commercial operations. Insect damage will be assessed each season to detect any upward trends in injury levels.

PROGRESS: Reduced insecticide programs were continued in 2 test orchards outlined previously and initiated in 1 new orchard. After 4 years of testing on the Eldredge Farm, Claverack, N. Y., the average of clean fruit has increased. The basic insecticide in this block is Sevin. There was, however, a slight increase in apple maggot and plum curculio injury. The test in Crist Brothers Orchard, Walden, N. Y. utilized Gardona as the basic insecticide. There was an indication of a slight weakness of the chemical for European apply sawfly control, but control of the other apple insect pests has been good. No fruit injury, such as occurred in 1968, was noted this year with Gardona due possibly to better spray conditions and a lower rate of application than last year. A new block was initiated this year at the farm of Sidney Mead, Red Hook, N. Y. Imidan was the basic insecticide and control was excellent for all apple insects. From the results of these tests, it is indicated that in commercial plantings, where insect population pressures are low, adequate control can be obtained by alternate side spraying or skipping every other cover spray. The data suggests, however, that alternate sides of the row spraying may be the preferred method.

SUPPORTED BY New York State Government - Albany

4.0766, TOXICOLOGY AND METABOLISM OF UNINTENTIONAL FOOD ADDITIVES

G.S. STOEWSAND, New York State Agric. Sta., *Geneva, New York* 14456 (NYG00629)

OBJECTIVE: Study the toxicity and metabolism of insecticides in animals with relation to specific nutritional and dietary effects and interactions.

APPROACH: Growing rats, consuming diets containing various amounts of protein, will be fed dieldrin or other insecticides that exhibit marked toxicity for mammals. If any interaction is indicated between the diet and the toxicity of the specific insecticide, further studies into the metabolism of the insecticide in the animals under various dietary regimens will be undertaken.

PROGRESS: A new organophosphate pesticide, 'Torak' is being studied regarding toxicity and metabolism in rats. This compound is 3-5 times more toxic in young female rats than males but no clear cut relationship is observed with quantity of dietary protein. 60% of this compound is eliminated via urine metabolites in 24 hours, and 40% is excreted in feces in 72 hours. Nitrate toxicity studies have shown that female Japanese Quail develop methemoglobin more readily than males. Feeding ascorbic acid has no effect in preventing nitrate-induced methemoglobin in this species. Additional studies with nitrate toxicosis and dietary ascorbic acid relationships in guinea pigs is under investigation.

SUPPORTED BY New York State Government - Albany

4.0767, EFFECTS OF CHEMICAL POLLUTANTS ON AVIAN REPRODUCTION

T.J. CADE, State University of New York, School of Agriculture, *Ithaca, New York* 14850

Our objective is to study the chronic, subiethal effects of organochlorine and other chemical residues on the reproduction of birds and to relate these effects to changes in population dynamics, especially in raptors. Specific aims are: in vitro studies of chemicals - especially PCB and toxaphene - that induce hepatic enzymes, which hydroxylate steroid hormones, and to correlate these effects with reproductive abnormalities; inhibition by chemical residues of carbonic anhydrase in the avian shell gland and correlation with eggshell thinning; inhibition of ATPase and glucose-6-Ca ion Na ion in the avian oviduct; studies on synergism between DDE and PCB in effects on eggshells of captive and wild Kestrels (Falco sparverius); monitoring selected

species of raptors in the field for eggshell changes, residue levels in eggs and tissues, changes in reproductive performance, and changes in numbers of breeding pairs. We are interested in these problems in relation to existing environmental levels of chemical pollution, and the two aspects of long- term chemical pollution that most concern us are synergism and the minimum chronic level of residues that initiated dysgenic reproductive effects.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.0768, FORAGE INSECT INVESTIGATIONS

G.G. GYRISCO, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00625)

OBJECTIVE: Study the biology, ecology, behavior and control of the insects of forage crops including alfalfa, clovers, birdsfoot trefoil, and corn; stressing the insects of alfalfa and in soil; with especial reference to the alfalfa weevil, alfalfa snout beetle, leafhoppers, plant bugs, spittlebugs, cutworms, European chafer, and rootworms.

APPROACH: Evaluate the effects of the insects on the yield and quality of forage crops, study their biology and behavior so as to control them better with parasites, cultural methods, resistant varieties, or insecticides, alone or in combination; thus to provide safe economical methods of pest control keeping the toxicant at a minimum with complete safety to dairy cattle, livestock, and in milk.

PROGRESS: Using sticky-type traps of 6 designs and 6 colors, alfalfa weevil flight and summer diapause was studied in open alfalfa fields and on alfalfa in large field cages. Alfalfa weevils flew with prevailing winds during their summer migration. Compass direction and distance from woods did not influence pre-flight orientation or flight direction. There may be an optimum range of wind speed necessary for maximum success in flight dispersal. No significant information in color preference was gained but weevils migrating in summer out of alfalfa to diapause sites in woods are not in a state of appetite behavior and really could not be expected to react to color as might be the case in fall and spring. Further work in these seasons is necessary. During August 5 fields in each of 6 counties were surveyed for the northern corn rootworm. A total of 600 plants were randomly examined in each field for visible damage and for adults, while the soil beneath 10 plants was hand-sorted for immature stages. Counts were generally low (less than 10/200 plants) and damage attributed to the insect was seen in only one field, not previously rotated.

SUPPORTED BY New York State Government - Albany

4.0769, EFFECT OF PROCESSING PROCEDURE ON MILK PESTICIDE RESIDUES WITH EMPHASIS ON RESIDUE REMOVAL

R.A. LEDFORD, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00171)

OBJECTIVE: Isolate representative microorganisms of the diverse flora associate with different varieties of cheese and to determine if their growth produces any degradation of chlorinated pesticides.

APPROACH: Different appropriate cheese types will be made with active isolates to ascertain pesticide degradation under commercial conditions.

PROGRESS: Cheese isolates of Brevibacterium linens and Geotrichum candidum were found to dechlorinate p-p DDT. Further, the growth of G. candidum appears to degrade DDE to unknown products. The identity of the breakdown products is under study. In cheese studies, where DDT was added to the milk and measurements of the residual DDT were made during the ripening process, casein was found to inhibit the pesticide degradation. The mechanism of this inhibition is being studied with particular emphasis on identifying conditions under which maximum pesticide degradation is achieved in fermented foods.

SUPPORTED BY U.S. Dept. of Agriculture

4.0770, RESIDUES IN OR ON RAW AGRICULTURAL COMMODITIES

D.J. LISK, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00637)

OBJECTIVE: Determine the content of pesticide chemicals, particularly at harvest, in or on raw agricultural commodities resulting from practical and experimental pesticide applications for control of pests above or below ground.

APPROACH: Plant growth regulators also will be considered. Analyses of milk, meat, poultry, and eggs for possible residues following experimental feeding of pesticide treated forage or grain crops also will be made. It is hoped that by proper combination of pesticide and method of application, that adequate pest control may be accomplished without exceeding legally established tolerance limits.

PROGRESS: During 1969, 1700 residue analyses were made including 19 agricultural chemicals and 17 commodities. Sensitive analytical methods were developed for an onion top killer, neodecanoic acid in onions, hexachlorophene fungicide in vegetables and a plant growth regulator, Ethrel. A new insecticide trapping system was developed for preparative gas chromatography. A method was adapted for analysis of mercury in soil and a silver-containing algacide in pond water. The metabolism of seven new agricultural chemicals (the insecticides Gardona and Hercules 14503 and the herbicides Amiben, Bromacil, Fenac, Herbisan and Planavin) were studied in dairy cows. Analysis of milk, urine and feces was conducted for these compounds and possible metabolites. The possibility of their decomposition in rumen fluid and liver microsomes was investigated to learn possible sites of metabolism. Most of this work has been submitted for publication. Research on analysis and metabolism of pesticides is essential for obtaining federal approval for pesticide use by the public.

SUPPORTED BY New York State Government - Albany

4.0771, STUDY OF HONEY BEES AND OTHER POLLINATING INSECTS AND PESTICIDE CHEMICAL MATERIALS

R.A. MORSE, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00143)

OBJECTIVE: Study the role of honey bees as pollinators, to acquire a knowledge of colony reproduction, to better understand evolution in bees, and to ascertain better ways of marketing honey.

APPROACH: Honey bees and wild bees are being collected, curated and determined to better understand the role of these insects in crop pollination. Reproduction in honey bees is being studied with observation hives and under controlled laboratory conditions; synthetic pheromones are being used to study their role in reproduction. In cooperation with the N.Y.S. conservation department, there is a continuing exploration of the effect of pesticides on bees. Honey and honey marketing are under investigation in cooperation with the Department of Food Science and the Finger Lakes Honey Producers Cooperative.

PROGRESS: A survey of the pesticides which kill honey bees in New York State showed that Sevin was present in 12 of the 13 samples of dead bees submitted for analysis. Observations of queen and drone honey bees taking mating flight in cages and confined areas, continued without any further knowledge being obtained and with our being no closer to the desired goal of having mating in confinement, than a year earlier. As a result of visits to two honey wine factories in Poland and observation of fermentations in that country, several new formulae for honey wine are being tested. Observations on the biology of swarming in honey bees have been completed and a thesis and final paper are expected shortly.

SUPPORTED BY U.S. Dept. of Agriculture

4.0772, MECHANISMS OF INSECTICIDAL ACTION

R.D. OBRIEN, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00119)

4. PESTICIDES

OBJECTIVE: Understand the precise mechanism by which insecticides, particularly chlorinated hydrocarbons, produce their toxic effects in mammals and insects.

APPROACH: The research for anti-enzyme activity in chlorinated hydrocarbons has been most unsuccessful, and the bulk of evidence suggests that these are agents which interfere with the organizational array in conducting membranes, rather than on enzymes. It is proposed to study the role of complex formation in the action of chlorinated hydrocarbons. Two initial procedures will be followed. One is to construct artificial membranes from materials which will provide a matrix into which one can insert membraneous material derived from mammalian and insect nerve tissue. The ion permeability and the electrical properties of these reconstructed membranes will be examined, particularly with a view to finding what properties are bestowed upon the system by the naturally derived component. Appropriate agents (including insecticides, transmitter substances, and selected drugs) will then be applied to the systems, and changes in the above properties, caused by complex formation between agent and natural membrane constituent, will be looked for.

PROGRESS: This study deals with the effect of insecticide upon materials (both synthetic and natural) incorporated into synthetic phospholipid bilayers, and the consequent effect upon the electrical and ion-permeability properties of those membranes. We have now mastered the technique of preparing such membranes from lecithin. Unfortunately, the failure rate is high and the lecithin has to be extensively purified following its preparation from eggs, every few weeks. Membranes may also be prepared from fully synthetic phospholipids, but they do not demonstrate the important properties which follow. With lecithin membranes (prepared in decane), we have been able to duplicate the observation of Mueller et al that the addition of 10 M valinomycin increases the conductance by 50-fold or more, an effect related to potassium flux. We have now reported that DDT at 3 x 10 M reverses this induced conductance. The effect of DDT is not given by dieldrin or lindane.

SUPPORTED BY U.S. Dept. of Agriculture

4.0773, TOXICOLOGICAL STUDIES OF DIELDRIN AND STEROIDS IN DOGS

W.J. VISEK, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00569)

OBJECTIVE: Study toxicological manifestations, reproductive performance and possible teratological effects in dogs following feeding of chlorinated hydrocarbon; study the effect of a chlorinated hydrcarbon on dogs fed simultaneously with hormonal substances; determine if the feeding of a commonly used chlorinated hydrocarbon and hormonal substances alter the ability of the liver microsomal enzymes to detoxify foreign compounds in dogs.

APPROACH: Beagle dogs will serve as experimental animals for studies of breeding and reproduction. Biochemical and enzymatic measurements will be carried out on all animals to determine ability to detoxify these and other agents when given intravenously. All animals will be necropsied and tissues will be analyzed for insecticide and evidence of damage due to the experimental treatments.

PROGRESS: The past calendar year represented the 4th year of this five year study upon the toxicological effects of dieldrin and steroids in dogs. Spermatozoa from males at bimonthly intervals have continued to show no changes attributable to treatment although there has been a sharp decline in prostatic secretion in 6 chloro-17 acetoxy-progesterone (CAP) fed dogs. Sixteen additional dogs were prepared with cystoprepuostomies to provide for collection of uncontaminated prostatic secretion. In such dogs CAP at 0.05 mg/kg/day reduced prostatic secretion 95% whereas with dieldrin 0.015 mg/kg/day plus CAP secretion decreased only 50% showing that the effects of exogenous female hormone on the dog prostate are decreased with dieldrin fed simultaneously. An interaction between 10 ppm dieldrin and CAP has also been shown in organ culture with dog and rat prostate. Testosterone reduces the toxic effects of high concentrations of dieldrin (10 ppm) on the dog prostate in organ culture. During the past year 36 male and 50 female dogs were necropsied for enzyme, histological and chemical analyses on 16 tissues per dog. These studies have shown no detrimental effects on reproduction when dieldrin is fed alone for 3 years at concentrations which are close to ambient levels. These studies have led to the development of a highly reliable biological system for detecting possible hormonal effects of chemicals in mammals.

4.0774, TOXICOLOGICAL STUDIES OF DIELDRIN AND STEROIDS IN DOGS

W.J. VISEK, State University of New York, School of Agriculture, *Ithaca, New York* 14850

This is the fifth year of a 5 year study upon the effects of prolonged feeding of an insecticide, dieldrin, in combination with hormones, 6-chloro-17-acetoxy progesterone (CAP) and methyl testosterone (MT) in purebred male and female Beagle dogs. The daily intakes in mg/kg body weight/day are 0.0015 and 0.015 for dieldrin, 0.05 for CAP and 0.15 for MT. Reproductive performance of adult dogs and their offspring has been studied. Spermatogenesis and testicular histology are under investigation. The effect of dieldrin with and without CAP and MT on prostatic secretion in mongrel dogs with cystoprepuostomies is being studied in vivo and in organ culture. In vivo blood, clearances for zoxazolamine have been determined at intervals and liver drug metabolizing enzymes have been studied in 68 animals after the treatment has been administered for more than one year. The females will be sacrificed this year and the males of the study have been necropsied. All assigned animals and a number of abnormal offspring have been or will be necropsied for gross and histological pathology and for analyses of insecticides.

4.0775, EFFECTS OF DDT AND DIELDRIN ON REPRODUCTIVE PERFORMANCE AND GROWTH OF MINK

H.F. TRAVIS, U.S. Dept. of Agriculture, Animal Science Research Div., *Ithaca, New York* 14850 (033400521333)

OBJECTIVE: Determine effects of DDT and analogs, and dieldrin on health, reproduction and growth of mink.

APPROACH: 128 female and 64 male mink will be fed on eight diets (16 females and 8 males per group) during one growth and reproduction cycle to determine the effects of 1, 2 and 20 parts per million of oral ortho-para DDT (O, P' DDT) and 1 and 5 parts per million of oral dieldrin. Lake Michigan coho salmon, and the DDT, metabolites and dieldrin found in coho salmon will also be fed. Weights will be taken monthly and reproductive performance will be recorded. Samples of feed and tissues will be analyzed for pesticide content.

PROGRESS: Decreases in reproduction in mink fed fish obtained from the Great Lakes has been attributed to possible pesticide contamination. That p,p'-DDT was the causative agent was ruled out by a 3 year study on successive generations of mink where daily ingestion of up to 100 ppm did not influence reproduction. However, some commercial DDT contains 20% of the o,p'-isomer of DDT and this was shown to the uterotrophic in rats and mink at Ithaca. Its effect on reproduction when included at 1, 2 and 20 ppm of the daily ration of mink was investigated. No effect of the pesticide on fertility or fecundity were noted. Nowever, 10 of 10 animals fed 50% Coho salmon in their diets failed to whelp. Analysis of the fish showed the presence of 2.87 ppm p,p'-DDT, 0.82 ppm p,p-DDD and 6.40 ppm DDE. When these metabolites were included in the normal ranch ration 10 females produced only 6 kits compared to 44 for 10 controls. Dieldrin at 1 ppm had no effect on fertility or fecundity while a slight decrease in fecundity was noted at 5 ppm. All animals had been on these respective diets for 120 days prior to mating. In addition, 4 of the 10 mink receiving Coho salmon died and another 3 were necropsied in an emaciated condition. These mink were hypersensitive and slightly ataxic when killed. No significant gross or microscopic findings were obtained. Most outstanding changes were in the periportal areas of the liver where inflammatory reactions were noted. The significance of these observations is not clear.

4.0776, NEUTRALIZATION OF ROTENONE WITH ACTIVATED CHARCOAL

H.A. LOEB, State Conservation Department, *Livingston Manor, New York* 12578

Objective: To develop a method of neutralizing rotenone products in streams with powdered, activated carbon.

Procedure: Neutralization of rotenone in streams is desirable for delineation of test sections. Activated carbon would be preferable for neutralization because it is non-toxic.

A range of concentrations of activated carbon will be tested against 1 and 5 ppm of Noxfish for one hour. Effective concentrations will be tested for shorter periods in an attempt to determine the lowest concentration which neutralizes Noxfish (reduce to less than 0.03 ppm) in a practical time of 15 minutes or less.

Five and 20 gallon aquaria will be used in 65 degree F. water baths. Minimum number of fish for final bioassays will be 11. Water will have a range in pH of 6.5 to 7.5.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0777, EGG COMPOSITION, MALATHION RESIDUES, AND MEAT QUALITY OF MALATHION TREATED HENS

K. MORGAREIDGE, Food & Drug Res. Labs. Inc., *Maspeth, New York* 11378 (HN1-23(C))

OBJECTIVE: Determine effect of malathion treatment by measuring residue in tissues of laying hens. Correlate date with nutrient content of eggs and quality of raw and cooked tissues from non-frozen or 6 month freezer-stored carcasses.

APPROACH: Use normal laying hens of known breed. Malathion treatments, 100 and 1000 ppm, avoid toxicity to hens, assures insecticide residues within tolerance limits. Collect eggs from control and treatment pens before dosing. Sample hens and eggs during treatment. Assay for residues of malathion and metabolites in raw and cooked muscles, liver, abdominal fat, egg yolks and egg whites. Obtain data on eating quality, cooking losses, yields, of meat, cooked and stored. Analyze whites and yolks of eggs before and after treatment for proximate composition and amino acid profiles; yolks for cholesterol, vitamin A, carotenoids, and fatty acid profile: glycerol fraction and phospholipid fraction.

PROGRESS: Laying young hens were placed on an 8-week feeding period to test levels of 100 ppm and 1000 ppm malathion in the diet on the nutritive value of the eggs and on the eating quality of the cooked meat. Neither level produced any toxic effect. Taste panel evaluations gave no indication of an effect on flavor of the cooked meat. Residues of malathion were found in less than 0.5 ppm only in chicken fat, egg whites and egg yolks. Chemical analyses of egg whites and egg yolks showed no effect on nutrients including proximate composition, fatty acid distribution, amino acids, and carotene.

SUPPORTED BY U.S. Dept. of Agriculture

4.0778, TISSUE STRUCTURE AND GROWTH OF RATS FED LARD CONTAINING INSECTICIDES

H KAUNITZ, Columbia University, School of Medicine, *New York, New York* 10032 (HN2-49(CA))

OBJECTIVE: Determine the influence of feeding lard from hogs that had been fed diets containing DDT, malathion and methoxychlor.

APPROACH: Feed rats from weaning diets identical in all respects except for the lard from hogs fed diets containing different kinds and levels of insecticides. Sacrifice groups of rats at 7 months and one year of age. Determine rate of growth and examine microscopically tissues removed at death.

PROGRESS: Thirty-three and 56-week feeding studies indicated little adverse effect when diets contained heptachlor or DDT except with relatively high levels of heptachlor or DDT. Weanling male rats were fed lards derived from hogs fed or sprayed with the insecticides under investigation. The diets were marginal with respect to iodine needs and contained 20 micrograms of iodine. Body weights and food intakes were measured regularly. Hearts, aortas, lungs, livers, adrenals, kidneys, stomachs, testes, thyroids, pituitaries, and brains were weighed and examined histologically. There were no differences among the groups except for the thyroids. The lards from hogs fed or sprayed with malathion contained insignificant amounts of malathion and thyroids were comparable to those in control rats. Thyroids showed signs of iodine deficiency that were significantly more pronounced in those rats fed lards containing high levels of DDT or heptachlor than in the control animals or in those containing levels of DDT or heptachlor within the range currently considered acceptable.

4.0779, BEHAVIOR OF DILUTE SOLUTIONS OF MERCURIC SALTS

T.Y. TORIBARA, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT(30-1)49)

From a toxicological point of view, the measurement of small quantities of mercury is a very important procedure. In the development of a method to do so, the surprising discovery through the use of Hg203 was the rather rapid escape of radioactivity from very dilute solutions. It is obvious that meaningful measurements cannot be obtained unless there is assurance that no losses had occurred in the samples.

It had been previously reported that certain bacteria normally present could reduce mercury to the elemental state which could then volatilize. Preliminary work indicated that even without the bacteria, dilute solutions would lose mercury. An understanding of the mechanism by which the loss occurs would indicate the proper action necessary to prevent it.

It is proposed to study the movement through the use of Hg203 in a closed system in order to find the conditions favoring the movement.

RESULTS: A thermodynamic consideration of the different oxidation states of mercury indicates that the most probable path is a reduction of the mercuric ion to the mercurous form. The mercurous form can then disproportionate to form one mercuric ion and one elemental mercury atom for each Hg2 super 2 plus ion. This mechanism would be favored in the more dilute solutions.

SUPPORTED BY U.S. Atomic Energy Commission

4.0780, COLLABORATIVE RESEARCH IN ENZYME INDUCTION BY CHLORINATED HYDROCARBONS IN BIRDS - ITS ECOLOGICAL SIGNIFICANCE

C.F. WURSTER, State University of New York, Graduate School, *Stony Brook, New York* 11790

Chlorinated hydrocarbons of agricultural and industrial origin have become widespread pollutants in the global ecosystem. Recently they have been shown to be inducers of hepatic enzymes that degrade steroids, including the sex hormones. This effect may be of great ecological significance. Livers from populations of selected species of birds will be assayed for enzymes induced by chlorinated hydrocarbons. Enzyme activity will be related to the concentrations of individual and of total chlorinated hydrocarbons in the liver and to the total chlorinates hydrocarbon and lipid content of the birds. Estimates of the number of different enzymes induced will be made. Experiments with caged birds will attempt to determine the metabolic relationships between the thin egg-shells observed in populations heavily contaminated by chlorinated hydrocarbons and the induced enzymes. The formation of medullary bone, which is a mobilizable source of calcium during egg-laying, is controlled by the steroid sex hormones, naturally in female birds and artificially in male birds. Experiments with domestic pigeons and American kestrels will determine the relationship between the measured enzyme activity and the amount of medullary bone formed. The possibility that the thin eggshells are caused by vitamin D deficiencies resulting from degradation of this steroid by the induced enzymes will be investigated. Since Vitamin A mobilization is also effected by estrogen levels in birds, eggs of contaminated birds might be deficient in Vitamin A. Vitamin A will therefore be determined in some eggs. Measurements of shell weight and thickness of sea bird eggs collected recently will be made and compared.

4. PESTICIDES

SUPPORTED BY U.S. National Science Foundation

4.0781, METABOLISM AND PHYSIOLOGICAL ASPECTS OF INGESTED HYDROCARBONS
P.W. ALBRO, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Natl. Insts. of Health, *Durham, North Carolina* 27709

The investigation is in progress of the relationship(s) of accumulation of dietary paraffins in animal tissues to such suspected pathologic effects as lipidoses, co-carcinogenesis, and interference with reticular endothelial functions as well as the role of pesticides, synergists and drugs in regard to metabolic pathways of individual hydrocarbons from defined diets.

Piperonyl butoxide has been found not to inhibit the conversion of administered hexadecane to bile acids after oral administration of the synergist.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.0782, EFFECT OF METHYLENEDIOXYPHENYL SYNERGISTS AND RELATED COMPOUNDS ON MICROSOMAL DRUG METABOLIZING ENZYMES
M. BICK, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Natl. Insts. of Health, *Durham, North Carolina* 27709

The investigation of the possible inductive or inhibiting effect of methylenedioxyphenyl pesticidal synergists such as piperonyl butoxide on microsomal drug metabolizing enzymes (e.g., aminopyrene, ethylmorphine and nitroanisole demethylases) in various tissues (lung, kidney, brain and small intestine) is in progress.

4.0783, THE INFLUENCE OF ENVIRONMENTAL AGENTS ON THE GENESIS OF RIBOSOMES IN MAMMALIAN CELLS
P.E. BRUBAKER, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Natl. Insts. of Health, *Durham, North Carolina* 27709

Due to differences in stability and physiological activity of ribosomes in dividing and non-dividing cells, studies have been initiated to: 1) determine the conservation of parental ribosomes in daughter cells and their capacity to support protein synthesis; 2) determine the rate of ribosome subunits biogenesis in daughter cells and their role in protein synthesis; 3) determine the degree these processes are altered in cells exposed to various environmental agents. Ribosome, ribosomal subunit and polysome levels change significantly as cell progress through the cell cycle. These profiles are markedly altered on cells treated with various chlorinated hydrocarbons. Alterations are being made to correlate the physiological effects of the pesticidal compounds with structure.

4.0789, EVALUATION OF THE ANIMAL AND HUMAN COMPLAINTS FOLLOWING THE SPRAYING OF SILVEX, 2,4,5-T AND 2,4-D IN GLOBE, ARIZONA
B.C. ELIASON, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Natl. Insts. of Health, *Durham, North Carolina* 27709

As the medical member of a governmental panel, a trip was made to Globe, Arizona to study the claimed herbicide damage to animals and humans. A complete report is being prepared.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.0790, METABOLISM OF PESTICIDAL SYNERGISTS
L. FISHBEIN, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Natl. Insts. of Health, *Durham, North Carolina* 27709

The retention, localization and elimination of methylenedioxyphenyl pesticidal synergists following i.v., oral, and intratracheal administration to the rat is being further elaborated using C14-labeled methylenedioxy ring and alpha-methylene-C14-piperonyl butoxide. Special focus is centered on the elaboration of the commonality of urinary and fecal and biliary metabolites following administration via the above three routes.

Unequivocal identification of the nature of the metabolites of pesticidal synergistic agents, their tissue distribution and rates of elimination following various routes of administration would be of value toward the better understanding of the mechanisms controlling enzymic detoxification of this important class of environmental agent.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.0791, THE EFFECT OF ENVIRONMENTAL CHEMICALS ON H1 VIRAL-INDUCED FETAL RESORPTIONS IN PREGNANT HAMSTERS
J.H. GAINER, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Natl. Insts. of Health, *Durham, North Carolina* 27709

The purpose of this research is to determine whether pesticides, heavy metals, or other drugs alter H1 viral-induced fetal resorption rates (FRR) in hamsters. Following last year's report

that sodium arsenite, mercuric chloride, cadmium sulfate, and certain vegetable oils (olive, corn, and cotton seed) enhanced the H1 viral-induced FRR's and also that pp' DDT influenced to a greater extent the FRR's than op' DDT or technical DTT, continued studies in this regard are being pursued. Experiments are now being conducted to learn the possible significance of interferon in these enhancements of fetal resorptions by the various drugs listed. The herbicide 2,4,5T has also been tested to determine its 50 per cent FRR when administered on days 8,9, and 10 of pregnancy, and to learn whether it has an influence on H1 viral-induced FRR. There are no indications that 2,4,5T does induce teratologies, and there is no indication of an enhancement of H1 viral-induced disease; if anything, when drug and virus are used concurrently, there appears to be a slight reduction in fetal resorptions.

4.0797, QUALITY IN PORK AS INFLUENCED BY CERTAIN PHYSICAL AND CHEMICAL CHARACTERISTICS

T.N. BLUMER, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC02019)

OBJECTIVE: Evaluate quality in pork by certain physical, chemical and/or physiological methods. Relate the results of quality evaluation to acceptability by sensory panel testing.

APPROACH: Physical measurements of pork carcasses to include carcass length, fat back thickness, loin eye area and lean cut yield will be determined and correlated with the average width of the split vertebra to include the dorsal vertebral processes. Marbling content will be determined visually and related to chemical fat and moisture content as well as sensory panel scores. Free moisture determinations will be made and correlated with muscle pH, weeping score, chemical fat, shear value, sensory panel scores and the in vivo measurement of muscle tissue partial pressure of oxygen. The free fatty acid content and the glucose and amino acid content of pork loin chops will be correlated with taste panel flavor scores. The effect of fat on flavor of pork loin chops will be determined using rehydrated, freeze dried pork chops freed of fat by solvent extraction. Variations in marbling content of pork carcasses of different breeds will be determined. In addition, the rate of marbling deposition commensurate with the growth of the pig will be evaluated.

PROGRESS: P,P'-DDT was fed to pigs during the normal fattening period at levels of 0, 20, 40, 80 ppm with the following objectives: 1) to determine pork tissues which contain residues of p,p'-DDT, 2) to quantitatively determine p,p'-DDT residues in all tissues sampled, 3) to determine if p,p'-DDT is metabolized by the pig and if so, to qualitatively and quantitatively determine residues of metabolites and 4) to determine the most appropriate sampling site(s) for routine tolerance checks on the best sampling site for metabolic studies. During the 10 week feeding period dietary p,p'-DDT was rapidly absorbed into the blood stream and accumulated in the subcutaneous fat after only 24 hours. A wide variety of fat, muscle, organ and gland tissues sampled at the end of the feeding period contained p,p'-DDT, p,p'-DDE and p,p'-DDD. In addition to the DDT compounds mentioned above, some tissues were found to contain other metabolites (liver and kidney). Samples from hogs of known breeding were evaluated for water-binding capacity.

SUPPORTED BY U.S. Dept. of Agriculture

4.0798, INFLUENCE OF NUTRITION ON INSECTICIDE RESIDUES IN CHICKENS

W.E. DONALDSON, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC03171)

OBJECTIVE: Determine the effects of various dietary modifications on the accumulation and disposition of insecticide residues in the tissues of chickens.

APPROACH: Starvation has been shown to increase the rate of DDT depletion from chick tissues by reduction of adipose stores with which the DDT is associated. The technique used in previous experiments has been to alternately starve contaminated chicks for 2 days and re-feed for 1 day. This technique will be used in subsequent experiments in conjunction with various drug additions to the diet. The purpose of drug additions will be to stimulate the body's general detoxication mechanisms. It has been suggested that non-specific stimulation of detoxication speeds the elimination of chlorinated hydrocarbon compounds from the body. Initial experiments will utilize iodinated casein and thiou-

racil to assess their effects on DDT depletion rates from the tissues of contaminated broiler chicks.

PROGRESS: Experiments during the past year have concentrated on the distribution of DDT and dieldrin in embryos and extra-embryonic mass in chicken eggs. Both pesticides are distributed in all embryonic tissues in relation to the amount of fat in the tissues. Uptake from yolk injections is rapid and considerable (up to 60% of injected dose in embryo at hatching). These studies give a base for studying metabolic effects of the pesticides on embryos and egg composition effects (embryo nutrition) on pesticide uptake. in other experiments, the effects of barbituric acid derivatives and sulfa drugs on rate of depletion of DDT from chick tissues is being studied. At this time, we are awaiting residue analysis data from the Pesticide Residue Lab.

4.0799, MECHANISMS OF ADAPTATION OF ORGANISMS TO PESTICIDES

F.E. GUTHRIE, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC03191)

OBJECTIVE: Determination of physiological mechanisms enabling organisms to adapt to exogenous chemicals and relation to pre- and postadaptive genetics.

APPROACH: Adaptation to toxic plants - examine the gross tissue distribution, binding of C toxicants (nicotine initially) to extra target storage sites (as proteins and fats), and comparative nerve membrane properites which permit entry or exclude toxicants. Adaptations of vertebrates - Initial work will involve selection of strains of mice resistant to DDT, DDVP, dieldrin, and Sevin. These mice will be used to determine the biochemical mechanisms selected by the breeding study. The primary systems to be examined are: detoxication, change in target enzyme, and storage (fat or protein binding).

PROGRESS: Four colonies of mice have been stressed at the LD-50 level for 12 or more generations and reproductive and physiological parameters of stress investigated. Despite these rather rigorous conditions, the stressed colonies do not appear to be significantly different from the control colonies with respect to overall reproductive capacity nor in such physiological phenomena as ability to degrade organophosphate insecticides, hydrolyze acetylcholine, and oxidize aniline. The response by the dieldrin colony indicated a rather small debilitating effect but the response was rather subtle. These results are of particular importance because they indicate that animals can adapt rather well to contaminants in the environment, and it is particularly comforting to note that no genetic effects have become evident over a large number of generations.

SUPPORTED BY U.S. Dept. of Agriculture

4.0800, POST HARVEST MOLDS AND DECAYS OF TOBACCO

G.B. LUCAS, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC02042)

OBJECTIVE: Determine: methods of handling tobacco to prevent damage by microorganisms; effects of pesticides, herbicides, sucker- control chemicals on microflora; if microorganisms play role in chemical changes during storage, ageing; if fungi, bacteria on tobacco harmful to smoker.

APPROACH: Make microfloral assay of tobacco treated with chemicals, pesticides, herbicides; examine smoke condensate of treated cigarettes for toxins to warm blooded animals; grow tobacco fungi in culture, assay for toxins, identify; grow pesticide free tobacco in phytotron, compare treated.

PROGRESS: Ten fungi, Aspergillus niger, A. flavus, A. ochraceus, A. ruber, A. repens, A. amstelodami, Alternaria tenuis, Penicillium brevicompactum, Cladosporium herbarum and Chaetomium dolicotrichum, isolated from moldy tobacco did not grow in N(2) or O(2). In N(2)-O(2) mixtures the greatest change in growth occurred between 1.0 and 5% O(2). In CO(2)-O(2) mixtures radial growth of all species increased with each quantitative decrease of CO(2). All species except A. niger grew faster in air than in 10% CO(2). By inoculating cigarettes with a known quantity of fungus spores, the growth rate of the fungus can be regulated, thus permitting the cigarettes to be smoked after progressive amounts of infestation. Effect of smoke and smoke condensates of cigarettes made from moldy and mold-free tobacco on the respiratory surfaces of hamster tracheae were initiated; data not not analyzed. Morphology of 4 thermophilic fungi, Talaromyces, Aspergillus, Malbranchia and Mucor was described.

4.0801, DETERMINE THE EFFECTS OF 4-AMINOPYRIDINE (DRC-1327, AVITROL 200) ON PEN-REARED PHEASANTS

S.H. RICHARDS, State Game & Fish Department, *Bismarck, North Dakota* 58501

Objectives: 1. To determine the effect of DRC-1327 on young pheasants whose parents had been subjected to the poison. 2. To determine the effect of DRC-1327 on pheasant chicks ages 2-6 weeks.

Procedure: Observe all hatched pheasant chicks whose parents were tested with DRC-1327 for abnormal behavior, physical abnoralities or pathology. Allow these pheasants chicks to reach adulthood and determine if they are capable of reproducing.

Repeat force feeding of 1-6 week old chicks to enlarge sample tested.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0802, EXCRETION OF CHEMOTHERAPEUTIC AGENTS

I.A. SCHIPPER, North Dakota State University, Agricultural Experiment Sta., *Fargo, North Dakota* 58103 (ND-H-16-001)

OBJECTIVE: Determine the rates and routes of elimination of the various chemotherapeutic agents. Determine the spectrum of activity of the various chemotherapeutic agents for organisms.

APPROACH: The usual procedures for administration of chemotherapeutic agents will be utilized. Rates and routes of elimination will be determined and provide the basis for further investigations of applicability of various dosages and combinations under field conditions.

PROGRESS: Sulfachlorpyridazine administered orally at 1 grain per pound body weight provided detectable blood levels for 60 hrs. post- administration (PA). Highest blood concentrations were obtained at 4-8 hrs. with maximum levels of 2.2 mg. Milk levels were detectable only in one animal up to 8 PA hrs. When administered at 2 gm/lb body weight, blood levels of a maximum of 5.2 mg were obtained. In general, all levels were higher for comparable PA periods than 1 grain/lb body weight administration, but detectable levels extended through 48 hrs. only. Milk levels at 2 grains/lb body weight were detectable in 2 cows only at less than 1 mg and for a maximum of 24 hrs. Sulfabromomethazine administered at 1 grain/lb body weight orally provided detectable blood levels up to 120 PA hrs. Maximum levels were obtained between 8-24 PA hrs. Maximum concentration recorded was 5.2 mg at 24 hrs. Milk levels were most eratic always below 1 mg. and in several instances, detectable up to 72 hrs. PA. When administered at 2 grains/lb body weight orally, detectable blood levels were maintained up to 120 PA hrs. The greatest concentration, 7 - 9.4 mg. was detectable at 24-48 hrs. PA. Milk levels of more than 1 mg. (1.6 mg.) was detected in only 2 instances. Detectable levels in milk was maintained up to 72 PA hrs. Microbiological examination of quarter samples of milk before and after sulfonamide therapy indicated no bacteriological genus or species changes associated with sulfonamide therapy.

4.0803, DIELDRIN TOXICITY IN THE CHICKEN

J.L. SELL, North Dakota State University, Agricultural Experiment Sta., *Fargo, North Dakota* 58103 (ND-S-07-011)

OBJECTIVE: Determine the toxicity of dieldrin, previously accumulated in adipose tissue, during severe dietary restriction.

APPROACH: Hens in individual cages will be divided into four equal groups and fed. a) Control ration ad libitum b) Control ration restricted to intake of dieldrin-fed hens c) Control ration

plus 10 ppm dieldrin restricted to lowest intake of dieldrin-fed hens d) Control ration plus 20 ppm dieldrin (this group will dictate restriction of groups b and c). Biopsies of abdominal fat at 4-week intervals for measurement of dieldrin storage. At end of twelfth week, feed will be removed and subsequent indications of dieldrin toxicity observed. Blood will be taken periodically during diet restriction to follow dieldrin mobilization. At termination the dieldrin content of the carcass will be determined. Subsequent research will depend on the findings.

PROGRESS: In the first of a series of experiments, 48 hens were fed rations containing 0, 20, 40 and 80 ppm dieldrin for a period of 8 weeks. Feed consumption was reduced by the addition of 40 or 80 ppm dieldrin and poisoning occurred in some hens fed dieldrin at the 20 ppm level. A like number of hens were fed rations containing 0, 10 and 20 ppm dieldrin in a second experiment. Feed consumption was equalized across treatments and at the end of 12 weeks, feed was removed. Survival following feed removal was 33, 28 and 19 days, respectively. A third experiment involving 60 hens fed dieldrin at levels of 0, 1, 5, 10 and 20 ppm is in progress and should conclude this series.

4.0804, METABOLIC FATE OF AGRICULTURAL CHEMICALS IN POULTRY

G.D. PAULSON, U.S. Dept. of Agriculture, Metabolism & Radiation Lab., *Fargo, North Dakota* 58103 (039900970136)

OBJECTIVE: Study the metabolism of carbamate pesticides in poultry by determination of the metabolic fate of the parent compound; investigation of tissue(s) and subcellular site(s) responsible for the metabolism; isolation and identification of metabolites; and investigation of the enzymatic reactions involved in the metabolism of these compounds.

APPROACH: Initial studies will be conducted on the metabolism of Sevin (1 naphthyl N methyl-carbamate). This compound is an effective insecticide and a representative carbamate pesticide. All studies will be conducted with carbon-labeled Sevin. In vitro studies will be conducted to determine which tissue(s) and subcellular site(s) is responsible for the metabolism of Sevin in the chicken. Studies will be conducted to isolate and identify the parent compound and/or metabolic products produced in the intact animal and in in vitro studies. It is felt that the three different experimental approaches (i.e., radioisotopic tracer studies with intact birds, in vitro studies with specific tissues and subcellular fractions, and isolation and characterization of metabolites) will complement each other, and, when used in combination, will give a more complete understanding of metabolism of these compounds.

PROGRESS: P-Chlorophenyl N-methylcarbamate (I) is a potentially useful synergistic agent for carbamate pesticides. Its metabolic fate has been determined in the chicken. When a single oral dose of the C ring-labeled compound was given, no C was recovered in the expiratory CO_2, but 94 to 97% of the C activity was recovered in the urine. When chickens were dosed with the carbonyl labeled compound, 68 to 83% of the C was recovered in the expiratory CO_2 within 48 hours. Only trace amounts of carbon-14 were detected in the tissues of the chickens when sacrificed 48 hours after dosing with the ring-labeled compound. Confirmation of structure was made by synthesis. Sixty-seven percent of the urinary metabolites was identified as p-chlorophenyl sulfate (II) and 29% was identified as p-chlorophenyl glucuronide (III). The major ether extractable metabolite in the urine (4%) was tentatively identified as p-chlorophenol (IV) on the basis of its chromatographic behavior.

4.0805, CENTER FOR THE STUDY OF THE HUMAN ENVIRONMENT

R.R. SUSKIND, Univ. of Cincinnati, School of Medicine, *Cincinnati, Ohio* 45221

The Center for the Study of the Human Environment is a research and educational resource devoted to the study of environmetal problems which affect man's health and to research training in pertinent scientific disciplines. The present subject areas on which coordinated research efforts are focused include (1) trace metal metabolism (2) toxicologic problems of heavy metals (3) carcinogenesis and teratogenesis (4) pulmonary problems of environmental origin (5) pesticides (6) organic solvents (7) plastics and (8) analytical and environmental methodology. The environmental origins of these problems are related to air and water quality, solid waste management, industrial and agricultural activity, and consumer products including food, drugs, household and other manufactured materials. The training program is intimately related to the research efforts and includes masters and doctoral programs in disciplines encompassed within the arena of environmental health.

4.0806, FURADAN INSECTICIDE RESIDUE STUDY WITH DAIRY CATTLE AND CHICKENS

R.E. COOK, Ohio State University, Agricultural Experiment Sta., *Columbus, Ohio* 43210 (OHOSS-164)

Objective: Determine whether residues from Furadan accumulate in meat, milk and eggs.

Approach: Preliminary tests have indicated that 2, 3-dihydro-2, 2- dimethyl-7-benzo furanyl methyl-carbonate (Furadan by Niagara Chemical Division) is a promising chemical for the control of alfalfa weevil. This investigation is designed to determine whether the residues of this chemical appear in meat, milk and eggs of cattle and chickens fed alfalfa treated with this chemical. Application of the pesticide will be carried out on alfalfa 14 and 28 days prior to cutting. Hay harvested from these plots (3 levels) will be fed to cows for 30 days. Residues in the milk and meat will be determined. Dried alfalfa meal prepared from these plots will be placed in the rations of laying hens and growing broilers. Residue levels will then be determined in the eggs and meat over 10 and 8 week periods, respectively.

Progress: Carbofuran, a promising chemical for the control of alfalfa weevil, was applied to alfalfa that was harvested and used as 55 to 64% of the feed of dairy cattle and as a dried meal for chickens to determine whether this carbamate or its residues would appear in the meat, milk or eggs. With alfalfa hays containing 3 levels of residue fed to dairy cows, detectable residues were found in the milk at all levels of feeding. The only carbamate residue detected was 3-hydroxy carbofuran. No detectable levels were found in liver, kidney, muscle or fat tissue samples from the cows during the 30-day feed period. Residues disappeared from the milk within forty-eight hours following withdrawal of the treated hay. No detectable residues were found in the meat or eggs when a ration containing treated dried alfalfa meal was fed to laying hens and growing broilers during a ten and an eight-week feeding period, respectively.

4.0807, THE EFFECT OF DIELDRIN ON SURVIVAL AND DEVELOPMENT OF FISH EGGS

R.A. TUBB, Ohio State University, Graduate School, *Columbus, Ohio* 43210

Dieldrin is the most commonly found insecticide in the major river basins of the United States (Breidenbach, 1967). Over 1.5 million acres in Ohio are treated annually with aldrin which is rapidly oxidized to dieldrin. Natural populations of fishes and fish eggs have been surveyed for dieldrin residues. Currently eggs from Stizostedion vitreum, Ictalurus punctatus and Polydictus olivaris are being subjected to concentrations of 0.05 ppb to 125 ppb dieldrin.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0808, THE UPTAKE OF DIELDRIN IN THE THREE RIDGED NAIAD, AMBLEMA PLICATA

R.A. TUBB, Ohio State University, Graduate School, *Columbus, Ohio* 43210

Amblema plicata occurs throughout the Ohio River drainage and is becoming increasingly important for export in the cultured pearl industry. Since this mollusk remains stationary for long periods of time, it can act as a pesticide monitor in streams. Recent studies have shown that naiads concentrate chlorinated

hydrocarbons. This study is an attempt to find the levels of dieldrin in natural populations and experimentally determine the uptake and excretion rates of the pesticide. The project was started in June, 1968 and will be completed in 1969.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0809, BIOLOGY, ECOLOGY, AND CONTROL OF INSECT PESTS
R.L. CAMPBELL, Ohio Agric. Res. & Dev. Center, *Wooster, Ohio* 44691 (OHO00399-S)

OBJECTIVE: Devise and develop means for controlling insect and mite pests which reduce the value of ornamental plants. Gain knowledge of the life history, behavior, and ecology of species of insects and mites which are injurious to ornamental plants.

APPROACH: Control programs will be devised. Life histories of various pest species and other insects associated with them (particularly parasites and predators) will be studied.

PROGRESS: Evaluation of methods and materials for control of pests of nursery stock and shade trees was emphasized. Specifically, work continued on the development of techniques for mass laboratory rearing of the black vine weevil, one of the ten most serious nursery pests in Ohio. Development of these techniques is prerequisite to controlled testing of experimental insecticides on this insect. A basic, chemically defined synthetic diet has been developed and is being adjusted. Various natural host plants and diet additives therefrom are being investigated. Current interest is in developing alternatives to field control with chlorinated hydrocarbons. Limited chemical control studies on spruce needle miner were undertaken using standard field screening techniques. An evaluation of materials for the control of maple bladder gall mite showed that carbaryl gave better control when applied in the spring than any other candidate material. Thiodan, and C-2307 gave better control than malathion, the previously recommended control. Acaricides effective in spider mite control such as Carzol, Temik, Morestan and Kelthane did not reduce the number of maple bladder gall mite and may have actually stimulated its increase by reducing predaceous mites. An evaluation of materials for control of the mimosa webworm showed that carbaryl, dimethoate and oxydemetonmethyl gave satisfactory reductions in larval populations.

SUPPORTED BY Ohio State Government

4.0810, STUDY OF THE PRODUCTION AND DISTRIBUTION OF THE CHOLINESTERASE ENZYME IN ORGANOPHOSPHOROUS POISONING
G. CLARK, U.S. Dept. of Transportation, Civil Aeromedical Institute, *Oklahoma City, Oklahoma* (000621)

It has been postulated, but never proved, that the development of tolerance to anticholinesterase pesticides is partly due to an increased rate of synthesis of the cholinesterase enzyme. There is also the possibility that the enzyme is not uniformly inhibited in all parts of the nervous system or in single neurons due to local variations of the blood-brain barrier or the histological characteristics of single cells. These factors will be studied in poisoned animals by sensitive, specific, histochemical techniques.

Work to date indicates several areas where additional work is needed to obtain answers to the question of how tolerance to an anticholinesterase pesticide develops. The presence of enzyme in the neurons of the hypoglossal nucleus indicates that synthesis of the enzyme occurs despite the presence of the poison. In the poison animals all cells of the hypoglossal nuclei were equally stained while only some of the axons of these cells were stained. This apparently indicates a failure of transport of newly synthesized acetylcholinesterase in the hypoglossal axons. With the same method, cells from control animals failed to stain.

1. Transport of Acetylcholinesterase in Nerve Fibers. The method of Weiss will be used to block transport of the enzyme down the nerve fiber. 2. Permeability of Neuronal Cell Membranes in Rats Poisoned with Disulfoton. 3. Comparison of Acetylcholinesterase in Neuropile of the 12th Nucleus.

4.0811, DETECTION OF PESTICIDE EXPOSURE - EVALUATION OF BLOOD CHOLINESTERASE VALUES
C.R. CRANE, U.S. Dept. of Transportation, Civil Aeromedical Institute, *Oklahoma City, Oklahoma* (000617)

During FY-68, several commonly-used methods of assaying blood cholinesterase levels were evaluated and compared for validity and interconversion of results. We also propose to study the effect of some new organophosphorus insecticides on the cholinesterase enzyme system, and to examine in more detail some of the interrelationships among the cholinesterases found in blood and brain, their various substrates, the compounds which reverse cholinesterase inhibition, and other enzymes which modify components of the total system. This information which is not available at this time should allow us to recommend a specific procedure for collection,handling, shipping and analyzing blood samples for cholinesterase activity. The study will also contribute to a better understanding of the relationship between human exposure to pesticides, the diagnostic tests used to evaluate exposure and the drugs used to treat pesticide poisoning.

Using the pH-Stat method of analysis, a detailed study will be made of the effect of the following on blood cholinesterase measurements: a) type of anticoagulant used, b) storage time, c) storage temperature, d) buffer capacity and ionic strength of assay medium, e) type of substrate used, f) presence of different types of anticholinesterase compounds,and g) presence of different types of CHE reactivating compounds. If time permits, we also plan to look at the effect of anti- CHE pesticides on related blood enzymes.

4.0812, BLOOD CHOLINESTERASE IN AERIAL APPLICATOR CREWS
C.R. CRANE, U.S. Dept. of Transportation, Civil Aeromedical Institute, *Oklahoma City, Oklahoma*

The change in cholinesterase concentration in the blood of an aerial applicator is presently the best indicator of the magnitude of his exposure to 'organophospate pesticide' during the spray season. Primarily because of CAMI's past efforts in recommending to aerial applicators a periodic cholinesterase test, and because of our research work in methodologies and sample handling, we have had many requests to perform this test for aerial applicators in the Southwest. During the past twelve months, the additional educational efforts being made by the Accident Prevention Specialists in the Region's GADO's have dramatically increased the number of these requests. In the situation where this test was unavailable to the applicators locally, we have felt a moral obligation to furnish the service, if possible. In addition to being a beneficial service to them, it has furnished us with research material for an epidemiological evaluation of the degree of pesticide exposure experienced by this segment of the flying population.

Blood cholinesterase assays will be routinely performed on samples transported to CAMI or on blood samples drawn from individuals appearing at CAMI in person. At the request of GADO personnel in our area, we will travel to a location where 15 or more aerial applicators have been assembled, we will present educational material for safe handling of pesticides and draw blood samples for analysis in our laboratory.

In the past 12 months, March 1969- February 1970, our laboratory analyzed approximately 200 blood samples from aerial applicators. Most of this activity was at the request of GADO Inspectors and was authorized through AC-110. It included samples from aerial applicator groups at Lubbock, Plainview, Pecos and El Paso, Texas, and from the Annual Aerial Applicator Meetings in Fort Worth, Texas, and Hot Springs, Arkansas, as well as from individuals who appeared in person at CAMI.

4.0813, NEUROPHARMACOLOGY OF CONVULSANT PESTICIDES - INTERACTIONS OF ENDRIN AND ANTICONVULSANT DRUGS IN THE CEREBRAL CORTEX OF ANESTHETIZED ANIMALS

A.M. REVZIN, U.S. Dept. of Transportation, Civil Aeromedical Institute, *Oklahoma City, Oklahoma* (000611)

Endrin and other cholorinated hydrocarbon pesticides (CHPs) are convulsant neurotoxins. They can induce, in an exposed man, hyperirritability, tremor, perceptual and behavioral disorders or seizures, depending on the dose. There is also evidence suggesting that exposure to these compounds may contribute to the development of epilepsy or related neurological disorders. Consequently, exposure to endrin or other CHPs is able to cause incapacitation of agricultural pilots and other critical personnel. These experiments are designed to provide information on the interaction of endrin with various of the clinically used, or suggested, anticonvulsant drugs. Such information will be immediately relevant to the selection of antidotes for endrin poisoning and to an understanding of the mechanisms of action of endrin in the brain. The studies will also provide information basic to the design of experiments using therapeutic procedures in the proposed studies on chronic poisoning (AM-F-69-PHB-11).

A number of studies have shown that the neurochemistry and neuropharmacology of cerebral cortex are similar in all mammals and birds. Therefore, squirrel monkeys, cats, pigeons and owls may be used in this study, since each offers unique advantages in isolating specific cortical functions for experimental analysis.

Previous work has shown that endrin selectively poisons visual relay nuclei and that endrin, lindane and DDT have separate, though overlapping, patterns of action and, presumably, receptor sites.

Document provided to SIE by the Highway Research Information Service.

SUPPORTED BY U.S. Dept. of Transportation - F.A.A.

4.0814, NEUROPHARMACOLOGY OF CONVULSANT PESTICIDES - ANALYSIS OF EEG CHANGES INDUCED BY CHRONIC ENDRIN ADMINISTRATION

A.M. REVZIN, U.S. Dept. of Transportation, Civil Aeromedical Institute, *Oklahoma City, Oklahoma* (000615)

Chronic exposure to endrin, and, probably, most other chlorinated hydrocarbon pesticides (CHPs) leads to electroencephalographic (EEG) changes which occur as a linear function of dose and thus seem to be a sensitive index of the extent of poisoning. There is, consequently, a possibility that the CHP-induced EEG changes could be used in the diagnosis of poisoning. If so, control of exposure, and therapy of and recovery from CHP poisoning could be put on a more rational basis than is currently the case. These experiments are designed to analyze EEG pattern changes induced by chronic endrin exposure to determine whether any such changes are sufficiently distinctive to serve as diagnostic criteria for poisoning.

Previous work from this laboratory has demonstrated that endrin causes generalized EEG changes with little or no effect on Evoked Potentials (EPs) save possibly for some effect on visual cortex.

Document provided to SIE by the Highway Research Information Service.

SUPPORTED BY U.S. Dept. of Transportation - F.A.A.

4.0815, PESTICIDE INDUCED MODIFICATION OF BEHAVIORAL AND BIOELECTRIC RESPONSES TO EXTERNAL STIMULI

A.M. REVZIN, U.S. Dept. of Transportation, Civil Aeromedical Institute, *Oklahoma City, Oklahoma*

Case reports and other available information indicate that there are long-term behavioural sequelae to exposure to organophosphorus (OP) pesticides. These effects could pose a greater hazard to aerial applicator personnel than the more obvious acute effects of OP poisoning, particularly since these long-term effects seem unrelated to blood cholinesterase levels or other diagnostic indices. Therefore, we will study the acute and long-term, behavioural and electroencephalographic (EEG), effects of OP poisoning. These experiments can confirm and specify the nature of the behaviour changes due to OP poisoning and can develop EEG criteria for diagnostic purposes. The techniques used in this study are also applicable to the study of other psychoactive agents.

OP pesticide effects on primate behaviour will be measured using conventional, well-standardized operant behaviour control techniques. Complex sequential visual discrimination and perception tasks must be performed by the animal to obtain rewards (e.g. food). The effects of OP poinsoning on performance of these tasks will be analyzed to isolate those aspects of behaviour specifically affected by the OP (e.g. visual pattern discrimination, attention mechanisms, etc.). Animals will be followed for periods of many months to permit study of long-term OP effects. Four 'behaviour control' chambers are available, so that four animals may be studied simultaneously. The control of the chambers, data acquisition and data analysis will be performed by the LINC-8 computer recently acquired. Indeed, it is only the use of this computer which makes this complex experiment practical. When definitive results are available the procedures used in these experiments will be combined with the electroencephalographic and related techniques developed and used in PHB-11. Correlations between behaviour and brain electrical activity will be sought to indicate specific diagnostic approaches to OP poisoning.

Last year was spent learning computer technology, programming the computer, and designing and acquiring behaviour chambers and interfaces.

SUPPORTED BY U.S. Dept. of Transportation - F.A.A.

4.0816, NEUROPHARMACOLOGY OF CONVULSANT PESTICIDES - ANALYSIS OF EEG CHANGES INDUCED BY CHRONIC ENDRIN ADMINISTRATION

A.M. REVZIN, U.S. Dept. of Transportation, Civil Aeromedical Institute, *Oklahoma City, Oklahoma*

Sensitive, precise and object clinical diagnosis of poisoning (e.g. by organochlorine pesticides) or similarly accurate evaluations of the effects of psychoactive medicaments are not now possible. However, chronic exposure to the chlorinated hydrocarbon pesticide (CHP) endrin, and most other CHP's leads to generalized electroencephalographic changes whose magnitude seems to be a nearly linear function of dose -- up to convulsive levels. These experiments are designed to measure and evaluate changes in brain bioelectric activity induced by chronic exposure to a toxic CHP (endrin), and to determine whether the change are sufficiently distinctive to serve as a basis for the diagnosis of poisoning. Bipolar macroelectrodes will be implanted in a variety of cortical areas and subcortical nuclei in squirrel monkeys. The leads from these electrodes will be bought out to connectors permanently attached to the animal's skull, so that recording may be made at any time, up to 3 years after recovery from surgery, by plugging a cable from the recording system into the connector on the animals . This general arrangement permits using an animal as its own control and permits the use of mildly restrained but unanesthetized animals, both critical factors to the success of this type of neuropharmacological study . Although EEG changes are of primary interest in this study, several types of visual evoked potentials (V.E.P.s) will also be analyzed since prior studies here have suggested that these might be selectively affected by endrin.

Previous work from this task has demonstrated that chronic endrin poisoning caused dose-related changes in EEG's in monkeys, but with little associated change in evoked responses. The importance of stress- induced at mobilization with attendant release of toxic levels of endrin occuring months after termination of endrin administration was also emphasized and the phenomenon confirmed. (Text abridged).

4. PESTICIDES

SUPPORTED BY U.S. Dept. of Transportation - F.A.A.

4.0817, TOLERANCE TO CHOLINESTERASE INHIBITORS - EFFECTS OF ANTIDOTES ON TOLERANCE AND RECOVERY

W.B. STAVINOHA, U.S. Dept. of Transportation, Civil Aeromedical Institute, *Oklahoma City, Oklahoma* (000612)

When aerial applicator pilots and ground crew are exposed to organophosphorus pesticides for long periods of time, tolerance develops, and most of the chemicals deleterious effects seem to disappear. The medical implications of the adaptation phenomenon, however, are not clear. The effect could be insidious in that certain neurological and neuromuscular functions could remain impaired, despite the appearance of normality. Recent studies have shown that subtle changes do occur in homeostatic mechanisms. This study should contribute to a better understanding of the requirements for protection from exposure and the medical management of chronic poisoning.

Studies on the physiological and biochemical effects, in 42 insecticide antidotes, atropine and pralidoxime, will be done: 1) influenceupon development of tolerance to the insecticides, 2) influence upon recovery after termination of exposure, and 3) changes that occur in the cholinergic system under the combined influence of poison and antidote. Rats will be given atropine or pralidoxime before, during, or after exposure to disulfoton and the effects upon previously established parameters will be evaluated. Measurements will be: 1) cholinesterase activity,2) acetylcholine concentration, 3) acetylcholine release, 4) neuromuscular activity, 5) muscle tone, and 6) control of body temperature. Adequate statistical evaluation will be done.

4.0818, METABOLISM OF HEXACHLOROPHENE, A POTENTIAL INTOXICANT

D.R. BUHLER, Oregon State University, School of Agriculture, *Corvallis, Oregon* 97331

Studies on the absorption, excretion and metabolism of 14C-methylene labeled hexachlorophene will be carried out in the rat and dog. The routes of excretion, the extent of metabolism and the distribution of drug and metabolites in tissues will be determined following oral and intraperitoneal administration of labeled hexachlorophene. Principal urinary and fecal metabolites will be isolated, purified and identified using thin layer and gas chromatography, IR, NMR and UV analysis and mass spectrometry. The possible induction or repression of microsomal drug metabolizing enzymes by hexachlorophene will also be investigated in rats after chronic feeding or periodic injection with the chlorinated bisphenol. Both the rate of hexachlorophene metabolism and the activities of selected microsomal mixed function oxidases will be determined in animals induced by treatment with hexachlorophene.

An understanding of the manner in which hexachlorophene is transported and metabolized in animals will help assess the toxic potential to man of this widely used chemical.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.0819, METABOLISM OF HERBICIDES AND TRANSFORMATION PRODUCTS

S.C. FANG, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00519)

OBJECTIVE: Investigate the rate of metabolic breakdown and accumulation of ingested herbicides by rats in relation to the age, sex and nutritional status of the animal; investigate the rate of metabolic breakdown and accumulation in rats of transformation products of herbicides isolated from plants; investigate the rate of metabolic breakdown of the compounds in question in relation to the amount of ingestion; investigate the effect of these chemicals on biochemical reactions of the organs where the chemical accumulates.

APPROACH: A single dosage of either toxic or non-toxic level of herbicides C on their transformation products (2,4-D, ATA, Monuron or Tillam) will be administered to rats by means of stomach tubes. The animals will then be housed in a metabolic cage and the respiratory CO(2) and excreta collected periodically and analyzed for C .

PROGRESS: C-Phenylmercuric acetate (PMA), labeled at phenyl or acetate moiety, was synthesized, and this herbicide was fed to rats in order to study its fate, and also the rate of elimination. The result revealed the cleavage of acetate, which was mainly eliminated as respiratory CO(2), while the phenyl group was completely excreted via the urine and feces. Total recovery study showed a difference in time for the elimination for different moieties of PMA molecules, e.g. 90- 95% of acetate carbons were eliminated in 24 hr., same amount of phenyl carbons required 5 days, and elimination of 70 to 80% of PMA mercury needed 7 days. Analysis of urine samples from rats given different labeled PMA showed the presence of small amount of unchanged PMA and several labeled metabolites either derived singly from acetate, phenyl, and mercury, or in combination, indicating the complexity of PMA metabolism in the rat. Second phase of work involved the in vitro study of absorption and transport of various labeled herbicide and some plant transformation products through the intestine membrane. The experiment was designed to explore the possibility of a relationship between the permeabilities and molecular size and functional group of various herbicides, and between the permeability and the rate of elimination. Incomplete results showed a greater transport for a smaller molecule amitrole than a larger molecule such as 2,4-D. One amitrole metabolite also showed to be less permeable than the amitrole itself.

SUPPORTED BY Oregon State Government

4.0820, ORGANIC MERCURIAL FUNGICIDES AND METABOLISM

S.C. FANG, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00654)

OBJECTIVE: Synthesize radioactive organic mercurials needed for this propose research such as phenyl-Hg -acetate, methyl-Hg - hydroxide, phenyl-C -Hg-acetate, phenyl-Hg-acetate-C . Investigate the fate and persistence of these labeled fungicides both in plants and in laboratory animals. Special attention will be made to the organic moiety as well as to the mercury atom. Determine the permeability, the rate of elimination, tissue distribution and cellular incorporation of applied labeled inorganic and organic mercury compounds in order to seek differences which may exist and could attribute to the differentiated toxicity of these compounds. Investigate the effect of these compounds on biochemical reactions of plant and animal tissues in which the mercury compounds are accumulated. Relate mercury binding in the particulate or soluble protein and its influences on some enzymic activities.

APPROACH: Both C-labeled and Hg-labeled mercurials will be used to study the elimination pattern, rate of clearance, tissue accumulation, intracellular distribution and the fate of these compounds in the rat in order to assemble scientific data regarding the toxicological and biochemical problems and to search a clear understanding of their toxic action.

PROGRESS: The metabolic conversion of lactate-1- C was examined in the kidneys of male rats in vitro by a radiorespirometric method. The CO(2) production patterns were monitored continuously by a flow detectro and a Vibrating Reed Electrometer. Kidney slices from rats receiving daily oral dose of 3 mg phenyl-mercuric acetate (PMA) or inorganic mercury (Hg) for 5-10 days gave, not only a reduction of total CO(2) production, but, a shift of CO(2) pattern. Generally, 90% of lactate-1- C was converted to CO(2) during a 24-hour period by kidney slices from control rats of which 75% was found in the first peak and 15% in the second peak. Both mercurial treatments resulted in a reduction of the first peak and 15% in the second peak. Both mercurial treatments resulted in a reduction of the first peak and an enhancement of the second peak. This change was more pronounced with PMA. Extraction of kidney slices with alcohol at various intervals and chromatographs of the extracts revealed the presence of 4 labeled metabolites.

4.0822, ENVIRONMENTAL TOXICOLOGY OF PESTICIDES
V.H. FREED, Oregon State University, School of Agriculture, *Corvallis, Oregon* 97331

The objectives of this proposed program are: 1. To conduct program integrated research on the toxicology of pesticide chemicals and other organic chemicals that may enter man's environment. 2. Investigate the toxicological effects of these chemicals at the several levels of biological organization. 3. To investigate the interaction of other environmental stressors on the toxicological effect of these chemicals. 4. To investigate the chemodynamics of environmental chemicals, particularly with respect to partitioning into exposed organisms across the organism's environment interface.

The research strategy involves identification of areas of lack of knowledge on the toxicology of a given compound, establishment of goals and objectives, and then programming the research to achieve these objectives. The data will be analyzed and synthesized applying kinetic analyses models, as well as other types of data analyses. A common pool of animals will be used in the experiments with an overall treatment or experiment with a primary chemical. Biological, biochemical analytical, and pharmacodynamic data will be obtained on aliquots from this common pool. Where stressors are to be studied these will be imposed as additional experimental variables on the common pool of animals.

4.0823, NEW OR IMPROVED TECHNIQUES FOR SAFE CHEMICAL CONTROL OF ECTOPARASITES OF DOMESTIC ANIMALS
R.L. GOULDING, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00515)

OBJECTIVE: Research new approaches to the use of pesticides for control of arthropod pests or parasites. Current emphasis to be on pesticide-polymer resin formulations. Evaluate existing or experimental procedures or products for efficacy and host toxicity.

APPROACH: Develop basic concepts of retention and desorption kinetics of existing pesticide-polymer formulations. Utilize these relationships as models to study other pesticides and other polymer systems in terms of retention times and desorption rates. Test promising new formulations or existing formulations for pest-parasite efficacy and host toxicity in cats, dogs and other domestic animals. Examine host-parasite metabolism of toxicants. Conduct field trials with more promising products.

PROGRESS: Concluded study on efficacy of aerosol sprays of Sendran and Sevin in control of fleas on dogs. Initiated and concluded study of irritant effect of Vapona-PVC resin collars on cats and dogs. Developed system for formulating pesticide in PVC plastisol. Tests for efficacy of PVC-pesticide formulations using mosquitoes, flies and fleas were developed and a program initiated. The feasibility of formulating insect attractants in PVC was studied and preliminary tests performed.

SUPPORTED BY U.S. Dept. of Agriculture

4.0824, THE BIOLOGY AND CONTROL OF ARTHROPODS AFFECTING MAN AND ANIMALS
R.L. GOULDING, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00097)

OBJECTIVE: Conduct investigations on arthropods affecting man and animals in order to develop information on: biological principles and techniques needed to design effective pest and disease vector control programs. Toxicological effects of newly developed pesticides on important arthropod parasites and disease vectors as well as pesticide residue problems. Economic importance of the effects on man and animals of these pests and disease vectors.

APPROACH: Test efficacy of new pesticides and other pest control techniques on a limited scale in Experiment Station animals and faculties followed by trials with the more effective materials or techniques under conditions representative of Oregon livestock management systems. Assess the toxicological effects of pesticides upon both individuals and population of hosts and parasites by means of appropriate studies in biochemistry, pathology and entomology. Where possible these studies will be related to possible economic effects as well as upon the more basic effects upon host-parasite physiologies and populations effects.

PROGRESS: Observation facefly problems in Oregon indicate irregularly distributed foci of annoyance with considerable temporal variations due to weather changes. Field observations on control techniques in use by ranchers continued. Cattle louse control trials involving the pesticide Gardona were initiated. A study on comparative pharmaco-dynamics of the pesticides Proban, Tiguvon and Ruelene in rabbits and feeding mosquitoes and ticks was concluded.

4.0825, EFFECTS OF PESTICIDES ON ESTUARINE ORGANISMS
R.A. MILLEMANN, Oregon State University, School of Agriculture, *Corvallis, Oregon* 97331

Studies are continuing on the establishment of a well-balanced community of organisms in laboratory models of an estuary. The chronic effects of Sevin and other pesticides on members of such communities will be studied. Studies are in progress on the effects of the insecticides Sevin and Dursban on the survival, growth, and reproduction of the Dungeness crab, the viviparous shiner perch, and the oviparous chum salmon. Biochemical studies on the modes of action of Sevin and its metabolites on estuarine organisms are continuing.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.0826, EFFECTS OF PESTICIDES ON ESTUARINE ORGANISMS
R.E. MILLEMANN, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00665)

OBJECTIVE: Evaluate the acute toxicity of Sevin to certain estuarine organisms.

APPROACH: Use short-term bioassays. Determine the effects of Sevin on a community of organisms in artificial mud flats. Follow the residual life and metabolism of Sevin in estuarine organisms and in their environment. Study compounds related to Sevin, as well as other pesticides.

PROGRESS: Studies on factors necessary to maintain animal communities in laboratory models on an estuary were completed. The effect of the insecticide Sevin on such communities will now be studied. Studies on the effects of Sevin on survival and growth of the Dungeness Crab were completed. A manuscript reporting the results has been accepted for publication by the Journal of The Fisheries Research Board of Canada. Studies on the effects of sublethal concentrations of the insecticide Dursban on reproduction and growth of shiner perch are being continued.

4. PESTICIDES

SUPPORTED BY Oregon State Government

4.0827, RELATIONSHIPS OF PESTICIDE APPLICATION TO PESTICIDE RESIDUES IN WILDLIFE
B.J. VERTS, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00734)

OBJECTIVE: Determine the responses made by populations of certain wildlife species to applications of representative chemicals commonly used as pesticides in Oregon, and assess physiological, behavioral, and pharmacodynamical mechanisms that may be responsible for some of these responses.

APPROACH: Changes in reproductive capacity, changes in behavior, changes in resistance to pesticides, rates of deposition of body-burdens of pesticides, rates of excretion of pesticides, and frequency of teratogenesis by pesticides, either singly or in combination, will be used to evaluate the impact that applications of certain chemicals have or have had on populations of wildlife species.

PROGRESS: An investigation of resistance to chlorinated hydrocarbon insecticides by non-target species of terrestrial vertebrates was completed. A report of findings on tolerances exhibited by two populations of ring-necked pheasants (Phasianus colchicus) to technical DDT was prepared, submitted, and accepted for publication. Median lethal concentrations (LC(50)) of p,p'-TDE and o,p'-DDT in diets of week-old pheasants were established. These LC(50)'s, combined with those established for week-old pheasants to p,p'-DDT, p,p'-DDE, and a technical formulation of DDT during 1968, were the subject of a second report submitted and accepted for publication. It was interesting to note that the LC(50) of the technical formulation of DDT was somewhat greater than that expected on the basis of the LC(50)'s of each of the analogs. An investigation of the effects on the behavior of ring-necked pheasants by sublethal doses of various insecticides was initiated. Apparatus to test and record the performance of birds is being developed.

SUPPORTED BY U.S. Dept. of Agriculture

4.0828, THE INFLUENCE OF PESTICIDES ON MORTALITY RATES OF BIRDS
H.M. WIGHT, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00864)

OBJECTIVE: Estimate mortality rates for species of birds before the pesticide era and compare these rates with those during the era of pesticide use. Compare mortality rates of subpopulations of key species in two or more geographic areas, and attempt to correlate the mortality rates of these populations with the history of pesticide application within the areas. Compare changes in mortality rates of species of birds with similar and dissimilar food habits within areas. Determine mortality rates of species that are consumers at various trophic levels in the food chain.

APPROACH: Life tables will be constructed from the banding data and mortality estimates derived by location, and span of years.

PROGRESS: Mortality rates have been estimated for 50 species of non-game birds with the aid of the CDC3300 Computer at Oregon State University. Mortality estimates have been made for four time periods: (1) prior to 1935 (2) 1936-1945 (3) 1946-1955 (4) 1956-1964. Regional subdivisions have been also made depending upon how much banding information is available for each species. A mathematical model has developed to relate mortality rates to production required to maintain stable population. These production requirements were then compared with observed productivity. Species fully analysed to date include: (1) Osprey (2) Barn Owl (3) Cooper's Hawk (4) Red-tailed Hawk (5) Brown Pelican. Of these five species, three are declining in North America (Osprey, Cooper's Hawk and Brown Pelican), one is remaining stable (Red- tailed Hawk), and one is uncertain (Barn Owl).

SUPPORTED BY Oregon State Government

4.0829, BIOLOGY AND CONTROL OF ENTOMOLOGICAL PESTS OF TREE FRUITS IN THE MID-COLUMBIA AREA
R.W. ZWICK, Mid Columbia Agric. Expt. Sta., *Hood River, Oregon* (ORE00371)

OBJECTIVE: Investigate, determine, and recommend control measures for insect and mite pests of pome and stone fruit crops of the area. This research includes, field evaluation of registered and experimental pesticides. Studies of the abundance and bionomics of beneficial forms parasitic and predatory on phytophagous pests and means of increasing their biological control through selective use of pesticides or other means. Studies of the life history and abundance of pest studies aimed at the application of chemical, cultural, or biological control methods for reducing their depredations to low levels.

APPROACH: Pesticide recommendations for commercial orchards are periodically reviewed and revised based upon continual field evaluations of registered and experimental compounds. Biological studies of insect pests and beneficial parasites and predators through trapping and observation of field populations are studied to enable more effective timing of pesticide applications to be followed.

PROGRESS: Pome Fruits: Evaluations of pesticides for pear psylla and mite pests have continued. One experimental compound was found to be superior against overwintering red mite eggs and pear psylla as a delayed dormant. Several materials such as Imidan for codling moth and pear psylla, Omite and Morestan for mites, have been incorporated into spray program recommendations. Studies on mite management on apples have indicated the principal deficiency in Hood River is lack of sufficient prey such as rust mites for phytoseiid predators in May-June and 1 or 2 well-timed selective acaracide applications in July-August may be necessary in most orchards. Studies of mite infestation on apple have indicated significant differences on seasonal fruit growth between low and moderate to high populations and we are continuing with studies on determining economic levels. The value of proper timing for pre- bloom applications against pear psylla has been evaluated and results demonstrated to area growers. Discriminatory dosages of many registered and experimental insecticides which preserve phytoseiid predators have been determined in plot and orchard evaluations.

SUPPORTED BY Oregon State Government

4.0830, DETERMINATION OF DDT LEVELS IN WHOLE FISH OF BROOK TROUT STRAINS FED CONTROL AND DDT TREATMENT DIETS
J.E. WRIGHT, State Fish Commission, *Harrisburg, Pennsylvania*

Objective: To determine if there are strain differences in levels of accumulation of DDT and its metabolites in mature brook trout.

Procedure: Mature brook trout males and females from sibling lots of inbred strains will be killed, after spawning, and frozen in aluminum wrap for storage at -20 degrees C. The specimens will be from sibling lots which have been maintained on (1) a control normal pellet diet and (2) this same diet to which DDT was added at 10 p.p.m. Specimens will be weighed and homogenized in chloroform-methanol (2:1) plus anhydrous sodium sulfate, the slurry filtered, and the chloroform removed in a Synder column placed in a flask on a steam bath. After addition of n- hexane, the liquid is washed three times with water to remove methanol, the washed extract filtered through anhydrous sulfate, and evaporated on a steam bath to dryness. The lipid residue will be weighed to determine percentage of fresh weight and then dissolved in petroleum ether and extracted in a separatory funnel by shaking with acetonitrile saturated with petroleum ether - four times. These extracts are evaporated to a small volume and taken up in n-hexane, then evaporated to 2 ml for injection of an aliquot into a Research Specialties Gas Chromatograph Model 600 equipped with an electron capture detector. Samples of standard solutions will be run periodically to check on recovery and for calibration. Levels of DDT and the metabolites in p.p.m. of the lipids will then be converted to an individual fresh weight basis

and statistical analyses (analysis of variance, t Test, etc.) performed to determine significance of differences between control and treatment diets and of differences among strains.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0831, TO DETERMINE LEVELS OF DDT AND METABOLITES IN SERUM, MUSCLE AND WHOLE FISH OF STRAINS OF SALMONIDS (ABBREV)

J.E. WRIGHT, State Fish Commission, *Harrisburg, Pennsylvania*

Objective: To determine levels of accumulation of DDT and metabolites in strains of lake, rainbow and brown trout and coho salmon and to determine the correlation between whole body levels and that in serum and muscle tissue of these species and of brook trout.

Procedure: Sibling lots of rainbow trout and coho salmon strains now being maintained on control diets and on those containing 10 p.p.m. of DDT will be utilized. Sibling lots of strains of yearling brown, lake and brook trout which will be sexually mature in the fall of 1970 will be subjected to these diets. Specimens of each lot will be taken periodically during 1970 and after spawning in the fall of 1970 and DDT and metabolites will be determined in serum, epaxial muscle fillet and the remnant whole fish. (Method of DDT determination was described on Job 1, Study 1). Statistical analyses of differences in insecticide levels between diets and among strains and species will be determined. Correlation analyses will be performed among levels found in serum, muscle, and remnant whole fish at each periodic sampling.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0832, THE EFFECT OF DDT ON EGG, FRY AND FINGERLING VIABILITY IN BROOK TROUT STRAINS

J.E. WRIGHT, State Fish Commission, *Harrisburg, Pennsylvania*

Objective: To select those brook trout strains which are most resistant to harmful effects of DDT and its metabolites accumulated in the tissues and eggs.

Procedure: Females of control and treatment lots described in Job 1, Study 1, will be spawned individually and mated to individual sibling males from control and treated lots. Samples of unfertilized eggs, as well as each spawned fish, will be analyzed for insecticide levels as described in Job 1 Study 1. Total egg number, size, fertility and viability records will be obtained for the individually spawned lots through the fry stage. Those progeny lots will be saved for breeding stock which show significantly higher viability.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0833, THE EFFECT OF DDT ON EGG, FRY AND FINGERLING VIABILITY IN LAKE, RAINBOW, AND BROWN TROUT AND COHO SALMON STRAINS

J.E. WRIGHT, State Fish Commission, *Harrisburg, Pennsylvania*

Objective: To select those strains of lake, rainbow, and brown trout and coho salmon which are most resistant to harmful effects on reproduction of DDT and its metabolites accumulated in the fish tissue and eggs.

Procedure: Females of control and treatment lots described in Job 2, Study 1, will be spawned individually and mated to individual sibling males from control and treated lots. Samples of unfertilized eggs, as well as each spawned fish, will be analyzed for insecticide levels as described in Job 1, Study 1. Total egg number, size, fertility and viability records will be obtained for the individually spawned lots through the fry stage. Those progeny lots which show significantly higher viability will be saved for breeding stock.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0834, SELECTIVITY AND MODE OF ACTION OF HERBICIDAL CHEMICALS

R.H. HAMILTON, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01434)

Objective: Investigate the physiological effects of herbicide treatment using resistnat and susceptible plants. Study uptake, distribution, and metabolism of important herbicides in susceptible and resistant species. Look for possible sites of herbicide action.

Approach: The studies will be concerned with influence that uptake, distribution and metabolism have on the concentration of herbicide accumulating at the active site in susceptible and resistant species. The studies will involve the use of C labeled or tritium- labeled herbicides to study the above factors. The work on possible sites of action will employ both the in vitro and in vivo approaches. Thus the effect of herbicides on intact plants or plant parts as well as its effect on isolated enzyme systems will be studied.

Progress: A major effort on this project was the tolerance of corn to 2-chloro-2-triazine herbicides. A mutant Pa. line was found to be low in benzoxazine derivatives and was more sensitive to atrazine. This was correlated with lowered ability of extracts from this mutant to detoxify atrazine to hydroxyatrazine. A survey of cereals indicated however no relation between benzoxazinone content and tolerance. Leaf concentrations of atrazine were also not related to acute toxicity. Preliminary work indicated it was possible to study intracellular localization of herbicides and plant growth regulators by radioautography and this effort was expanded with the USDA Grant No. 12-14-100-8075 (34). Recently we have identified detoxification pathway for 2,4-D in plants as formation of a major glycoside of 2,5- and 2,3-dichloro-4hydroxyphenoxyacetic acid. Four publications have resulted from this project.

SUPPORTED BY U.S. Dept. of Agriculture

4.0835, EFFECT OF INSECTICIDES ON POPULATIONS OF PARASITES OF THE ALFALFA WEEVIL

A.A. HOWER, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (00ENTC08334001CA)

OBJECTIVE: Determine the impact of insecticides applied to control the alfalfa weevil on the populations of parasites introduced against the weevil.

APPROACH: Field observations and laboratory tests will be made to determine the impact of the use of insecticides on the effectiveness of adult parasites; the impact of insecticides on parasite development and survival; the efficiency and dynamics of the parasites in the absence of insecticides; the efficiency and dynamics of the parasites following insecticide application; and the compatibility or lack of compatibility of spray schedules with parasite activity.

PROGRESS:

SUPPORTED BY U.S. Dept. of Agriculture

4.0836, PESTICIDE RESIDUES IN OR ON RAW AGRICULTURAL COMMODITIES

A. KURTZ, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01804)

OBJECTIVE: Determine pesticide residues on plants and animals. Develop standardized sampling and analytical methods for pesticide residues. Distribution and coordination of pesticide residue information.

APPROACH: Determine residues on fruit, vegetable, forage and animal products. Chemical and biological methods of residue analysis will be used. Emphasis will be on developing methods for new chemical analyses, determining pesticide residue on untested crops, and improvement of methods not now entirely satisfactory. Research data from all NE stations will be coordinated, residue disappearance curves on all types of crops will be prepared, and other pesticide information of value to this and other regions will be distributed.

PROGRESS: A micro florisil cleanup method as described by Henry F. Enos, et al., Perrine Primate Research Branch, USPHS, Perrine, Fla., was instituted. The method involves the grinding of 500 mg samples in Dual tissue grinders, handling of small liquid volumes with disposable Pasteur pipettes, and the use of only 1.5 g florisil for the cleanup stage. A large number of animal parts and organs have been analyzed with these procedures. The technique is now being used to analyze all fat samples from cattle adipose tissue, milk butterfat, and fish oils. Apple pomace has been found

to be an effective and safe cattle feed in Pennsylvania in using current processing methods and at current DDT contamination levels. Fat samples contained no more than 3 ppm total DDT when fed pomace for six months. Lake Erie Coho salmon, caught near the Pennsylvania shoreline, were found to contain DDT within the legally prescribed limits. Maximum concentration was found to be 1.2 ppm based on whole fish filet. A collaborative butterfat analysis study for BHC was completed under the auspices of the FDA District Laboratory in Buffalo. Methods generally were found to be good and in needed areas corrective procedures are being instituted. The Pennsylvania Station is cooperating with other Pennsylvania Laboratories and the Buffalo FDA Laboratory in monitoring and attempting to solve a serious BHC milk contamination problem. Cows high in BHC are being given special rations in an effort to reduce the contamination.

SUPPORTED BY U.S. Dept. of Agriculture

4.0837, BIOCHEMISTRY AND PHYSIOLOGY OF ADIPOSE TISSUE OF MEAT ANIMALS

J.D. SINK, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01611)

OBJECTIVE: Determine the cheimcal and physical properties of adipose tissue, study the metabolic dynamics both within and between the adipose tissues, and investigate the effect of ante-mortem and post- mortem treatments on the properties and the dnyamics of adipose tissues.

APPROACH: The panniculus adiposus and the capsula adiposa of cattle, sheep and swine will be studied. The chemical and physical systems/components, their interrelationships and their stability post- mortem will be investigated using the usual analytical, biochemical and radiochemical techniques. In addition, more complex techniques, i.e. electronmicroscopy, mass spectrometry, ultracentrifugation, activation analysis, chromatography (gas-liquid and thin-layer), will be employed. Growth studies and feeding trials will be conducted to study the effect of nutrition and aging on the development of lipid synthesizing and metabolizing systems.

PROGRESS: A study was conducted in an effort to find a sensitive and rapid analytical procedure for the determination of organochlorine pesticide residues in adipose tissue. Results of using neutron activation and gamma spectroscopy techniques with the short-lived chlorine-38 isotope indicated this procedure would have potential as a rapid, reliable method of determining organochlorine hydrocarbon content of animal tissues. In another study, work continued on the isolation and identification of the sex odor components in swine. A preliminary report was issued describing a ketonic and a hydroxy steroid that may be responsible for this odor. Work was also initiated in an effort to study the morphological changes that occur in porcine adipose tissues during growth. Cell number and size as well as lipase activity was studied.

SUPPORTED BY U.S. Dept. of Agriculture

4.0838, EFFECTS OF PESTICIDES ON INSECTS, MITES, AND PREDACEOUS ARTHROPODS IN APPLE ORCHARDS

E. NIEMCZYK, Res. Inst. of Pomology, *Skiermiewice, Poland* (480E21ENT16)

OBJECTIVE: Determine role of predators in controlling outbreaks of pest species and effects of pesticides on density of predators in apple orchards. Determine which pesticides are least detrimental to predaceous arthropods.

APPROACH: Laboratory studies will include effectiveness of predators in controlling red mites and aphids, predator preference for pest species, effects of pesticides on predators, and persistence of toxicity of pesticides. The main studies will be in apple orchards on population densities of red mite, predators and other pest densities. Fungicides and insecticides will be tested in apple orchards.

PROGRESS: Populations of red spider mites reached 120 mites/leaf during the season. The most abundant predaceous insect in the orchards sampled were Anthocoris nemorum, Propylea sp., Plaziognatus arbustrorum and Stethorus punctillum. The bark bug, A. nemorum, overwintered as an adult. Field-collected females laid 47-83 eggs each over a period of 11-28 days. Nymphs required 24-34 days to complete development through the 5 nymphal stadia when reared on Aulacorthum circumflerum, Myzus persicae or Panonychus ulmi. From 56 to 72% of the larvae reached the adult stage when reared in the laboratory. Experimental evidence indicated that mites were not a primary food of A. nemorum; thus this predator may be of relatively little value in regulating mite populations under field conditions. Studies with 19 pesticides and their effect on predaceous insects and phytophagous mites were conducted. There did not appear to be any correlation between pesticide treatments and populations of predators and phytophagous mites that would clearly indicate ways of maximizing predator benefits and minimizing use of chemicals.

SUPPORTED BY U.S. Dept. of Agriculture

4.0839, CORRELATION OF STRUCTURE VS. ACTIVITY OF POLLUTANTS OF FRESH WATER

H.W. BOND, Univ. of Rhode Island, School of Pharmacy, *Kingston, Rhode Island* 02881

A series of vinyl sulfones will be synthesized and screened for potential molluscicidal activity against Australorbis glabratus, an intermediate host for human schistosomiasis. The mechanism of action of active compounds in this series will be investigated through the use of in vitro systems prepared from snail tissue. Structure activity correlations will be determined through the use of in vivo and in vitro systems. 'No effect levels' of potentially useful molluscicides in terrestrial animals will be determined.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

4.0840, DEVELOPMENT AND APPLICATION OF QUANTITATIVE CELL CULTURE METHODS TO ENVIRONMENTAL PROBLEMS IN CHEMICAL TOXICOLOGY

B.H. PRINGLE, U.S. Environ. Protection Agcy., Northeastern Water Hyg. Lab., *Narragansett, Rhode Island* 02882

The overall objective is the development of a sensitive bioassay system for general toxicological studies involving chemical pollutants: Emphasis is on the screening of chemicals for physiological and genetic damage. Specific objectives include an evaluation of comparative toxicity, determination of the presence or absence of genetic effects, development of methodology permitting the recognition of no-threshold events, and the establishment and quantitation of dose effect relationships.

Accomplishments of 1971: Toxicity titration studies were conducted for several selected chemicals, including cadmium, zinc, copper, and NTA, using standard cell plating efficiency techniques. In addition, the kinetics of divalent cadmium toxicity was investigated and a quantitative model constructed to describe the kinetic curves. The titration and kinetic studies served to demonstrate that reproducible quantitative data could be obtained for cell killing, and that evaluations of relative chemical toxicity could be made by comparison of titration end points.

Objectives for 1972: A. An immediate objective for FY-1972 will include the completion of kinetic studies for zinc. B. Preliminary investigations of the genetic effects of chemicals will be initiated using a standard strain of chinese hamster cell (CHO-K1) cultured in vitro. Initial studies will involve the evaluation and standardization of methodology for the inducement and quantitation of damage at the cytogenetic level, and for the inducement and isolation of single-locus mutants using known mutagens. Upon standardization and/or modification of these techniques, assays with selected chemicals will be carried out. In this phase of the genetic studies, emphasis will be placed primarily on the quantitation of dose relationships between cell killing, cytogenetic damage, and production of single-locus mutations.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P.

4.0841, PARASITES OF POULTRY, BIOLOGY, DISTRIBUTION AND CONTROL

J.R. ADKINS, Clemson University, Agricultural Experiment Sta., *Clemson, South Carolina* 29631 (SC00134)

OBJECTIVE: Make a survey on the various external parasites. Study the biology and relate to control. Investigate insecticides for control of the external parasites. Investigate systemics. Investigate the toxicity of the newer insecticides to poultry.

APPROACH: Develop rearing techniques and life history of some of the more important species.

PROGRESS: Tests with Brofene were continued against Dermanyssus gallinae (DeGeer) and Ornithonyssus sylviarum (C. & F.). The miticide Acaralate was used against these mites. Brofene at 0.5% gave excellent control for 2 weeks and 1% for 4 weeks. Acaralate did not give satisfactory control. A synthetic pyrethroid aerosol (neo-pynamin) was as effective in the elimination of house flies from a turkey house as was natural pyrethrum.

SUPPORTED BY U.S. Dept. of Agriculture

4.0842, PHYSIOLOGICAL AND BIOCHEMICAL MECHANISMS OF HERBICIDAL ACTION

N.D. CAMPER, Clemson University, Agricultural Experiment Sta., *Clemson, South Carolina* 29631 (SC00799)

OBJECTIVE: Examine interactions between herbicidal chemicals and proteins; determine effects of selected herbicides on other cellular components such as isolated enzyme activities and membranes and their functions; examine interaction of selected herbicides and soil microorganisms.

APPROACH: Emphasis will be on non-ionic chemicals, i.e., phenyl ureas, acylanilides, substituted anilines, s-triazines, and substituted carbamates. Ionic chemicals to be included are the bipyrilidium compounds. Environmental factors and molecular groups of proteins and herbicides will be studied to establish the mechanism of action. Enzymatically prepared protoplasts will serve as a tool to examine effects on membranes and their functions. In vivo and in vitro aspects of soil microflora-herbicide interactions will be studied to identify overall effects and specific organisms that affect selected herbicides.

PROGRESS: A new technique, the Sephadex Dialysis Method (SDM), was established to determine sorption parameters; it gave identical results to the partitioning technique. Sorption of relatively water-insoluble chemicals can be determined by SDM at varying concentrations. Sorption of atrazine and trifluraline by SDM increased with increasing protein concentrations and varies with the type of protein examined. Ornithine transcarbamylase from pea seedlings was comparatively inhibited by several phenylcarbamates and phenylureas. Inhibition increased with increased chlorination of the phenyl ring. The enzyme is located at a control point in metabolism and may be one site of herbicide action. Surveys of soil microflora in soils treated over several years with repeated applications of 2,4-D or trifluralin revealed, as in a previous survey, a decrease in fungi and an increase in actinomycetes in the trifluralin plots and a decrease in bacteria in the 2,4-D plots. Picloram, paraquat and diquat slightly inhibited and ioxynil (25 ppm) completely inhibited growth of Erwinia caratovora in liquid culture. The bacterium appears able to utilize ioxynil as its sole carbon source. Living protoplasts have been prepared from tomatoes by digesting the tissue with pectinol. This technique will facilitate the study of membrane transport of herbicides and their effects on membrane transport of other materials.

SUPPORTED BY U.S. Dept. of Agriculture

4.0843, BIOLOGY AND CONTROL OF ARTHROPODS ON SOYBEANS

S.G. TURNIPSEED, Clemson University, Agricultural Experiment Sta., *Clemson, South Carolina* 29631 (SC00908)

OBJECTIVE: Identify species of insects associated with soybeans, determine their economic importance and investigate biology and seasonal history of destructive and beneficial species. Develop management systems for pest species.

APPROACH: Weekly samples of insect pests, parasites, and predators will be taken using D-Vac, beating and sweeping techniques. Feeding habits of mole crickets inhabiting soybean fields will be investigated to determine the status of this insect as pest, scavenger or predator. Ovipositional and feeding responses by Mexican bean beetles will be compared on soybeans with different physical characteristics. Seasonal development of thrips and leafhopper populations will be determined on different isolines of the Clark and Lee varieties. Efficacy of different insecticides will be compared against pest species. Consideration will be given to timing of applications and selection of chemicals that leave no harmful residues on the crop or in the soil. Special emphasis will be placed on determining the role of parasites in supression of pest populations and the effect of pesticides on field populations of the more efficient parasites.

PROGRESS: Identification & economic importance: Vacuum samples were taken throughout season from untreated and insecticide-treated soybeans. Samples were frozen and processed to determine seasonal and treatment differences in insect and spider populations. Velvetbean caterpillar damaged pods of soybeans in late Sept. Economic importance of this damage was negligible. Interaction of insecticides, pests & parasites: Increases in numbers of earworms and decreases in predators and a possible parasite, Copidosoma truncatellum, were observed in plots treated with Temik or Azodrin. This indicates that more attention should be paid to type and timing of pesticide applications. Resistance of soybeans to damage by Mexican bean beetle: A high degree of resistance was observed in a line of Japanese origin from soybean maturity Group VII. This line is being utilized in a breeding program to develop resistance to Mexican bean beetle. New varieties will be evaluated for agronomic characteristics and resistance. Performance of insecticides: 3 non-persistent insecticides (Azodrin, Lannate & Monitor) continue to exhibit wider efficacy against pest than currently recommended materials.

SUPPORTED BY U.S. Dept. of Agriculture

4.0844, PHYSIOLOGICAL AND BEHAVIORAL EFFECTS OF INSECTICIDES ON CORMORANTS

Y.A. GREICHUS, South Dakota State University, School of Arts, *Brookings, South Dakota* 57006

A multidisciplinary research program will determine the effects of DDT and its metabolites, DDD and DDE, on penned and wild cormorants. Previous studies in these laboratories have determined residue levels of organochlorine pesticides at all levels of the food chain in the immediate ecosystem from which the birds were captured. The fish-eating cormorant, at the top of this food chain, has been shown to have average levels 270 times greater than fish, which have the next highest levels.

The objectives of this research are to determine the levels and tissue distribution of organochlorine pesticides in these birds and to relate these to the pathological and clinical findings and to the individual and social behavior of these birds. These findings will also be related to the numbers and types of endo-and ectoparasites found in and on the birds being studied.

SUPPORTED BY U.S. National Science Foundation

4.0845, PESTICIDE RESIDUES AND PARASITES IN BIG GAME MAMMALS

E.J. HUGGHINS, South Dakota State University, Agricultural Experiment Sta., *Brookings, South Dakota* 57006 (SD00444)

OBJECTIVE: Assay the pesticide residue levels, in the big game mammals. Include whitetail deer and mule deer, pronghorn antelope, a sampling of elk and bison, a sampling of bighorn sheep and mountain goats. Study helminths and ectoparasites of these same big game mammals, patricular reference to those occuring in or on domestic livestock.

APPROACH: Viscera of deer and antelope will be collected. Also, a few animals will be taken during other seasons, and a sampling of other species of big game of more limited distribution will be taken. Fat and other tissues will be analyzed for residues of chlorinated hydrocarbons by gas chromatography procedures. Areas will be checked for past history. The viscera will be examined for helminths, and where possible.

PROGRESS: Work since 1965 has indicated that whitetailed deer, mule deer, pronghorn antelope, and elk of South Dakota to have detectable residues of several pesticides but that the levels are so low as to be of little concern at present. As to parasitic worms, the deer, elk, and bison have light helminth infestations, while the antelope have relatively heavy worm bur-

dens, particularly stomach worms. A preliminary survey of the parasites of mountain goats from the Black Hills during the past year indicates a serious lungworm infestation in the herd. Preliminary life cycle studies have been initiated with terrestrial snails collected from the mountain goat range. This infestation is believed to be the most pressing problem among the big game mammals at present. Moreover, the mountain goats harbor heavy infestations of stomach worms, which are also among the most damaging of the worm parasites. This work will be pursued.

SUPPORTED BY U.S. Dept. of Agriculture

4.0846, A STUDY OF THE PESTICIDE RESIDUES AND OF PARASITES IN BIG GAME MAMMALS OF SOUTH DAKOTA

E.J. HUGGHINS, South Dakota State University, Agricultural Experiment Sta., *Brookings, South Dakota* 57006 (SD00507)

OBJECTIVE: Study the epidemiology of the lungworm infection (Protostrongylus rushi and P. stilesi) in the mountain goats of the Black Hills. This will involve studies on the distribution, ecology, and bionomics of the terrestrial snails which serve as the intermediate host. Determine what part, if any, the bighorn sheep of the Black Hills may play in the epidemiology of lungworm. (Lungworms were found in two bighorn sheep from the Badlands of South Dakota). Analyze kidney fat from the mountain goats for pesticide residues, in order to round out the picture for big game mammals of South Dakota. Samples will be collected during the limited fall hunting season for mountain goats in the Black Hills.

APPROACH: Maintain snails in the laboratory and subject them to infection with lungworm larvae for controlled studies. Lungworm eggs and larvae can be recovered from infected lungs collected during the limited hunting season. They are extremely resistant to both freezing and dessication and apparently remain viable for long periods in the freezer or refrigerator. Lungworm larvae can be recovered also from fecal pellets of mountain goats. Search for an effective drug which can be incorporated into salt blocks and made available to the wild goats on their range. This will entail attempts to infect domestic sheep with the lungworms for drug trials, etc.

PROGRESS: Lungs and viscera of mountain goats were obtained from the fall hunts of 1968 and 1969, and a high incidence of lungworm infection was found, as well as many helminths of the gastrointestinal tract. The latter have been identified and tabulated. With regard to the life history of the lungworms (Protostrongylus), many tiny terrestrial snails were collected on the mountain goat range and several different species have been identified by a specialist at the Smithsonian Institution. Several of these species of snails have been subjected to experimental infection with lungworm larvae, with successful infection occurring in at least one species of snail. A number of experimentally infected snails were fed to two domestic lambs, but results were negative. Samples of kidney fat from 13 mountain goats were analyzed for pesticide residues. Very low levels of several chlorinated hydrocarbons were found.

SUPPORTED BY U.S. Dept. of Agriculture

4.0847, RELATIONSHIP OF INSECTICIDES TO PHEASANTS IN SOUTH DAKOTA

K.E. SEVERSON, South Dakota State University, Agricultural Experiment Sta., *Brookings, South Dakota* 57006 (SD00438)

OBJECTIVE: Phases 1 and 2 completed. 3rd phase - to determine the effect of pesticides on juvenile pheasants. 4th phase - to determine effect of pesticides on reproductive behavior of hen pheasants.

APPROACH: 3rd phase - two section. 1. Controlled study where birds fed known amounts of aldrin (4 levels: 0.0, 0.5, 1.0, 1.5 mg/bird/wk for 7 weeks). Data gathered will be rate and date of primary feather growth, wt. gain, food consumption, residue in tissue. 2. Broods released in 1 - acre enclosures - 2 treated with 2 lbs. aldrin 1 acre, 2 controls. Data gathered on mortality, food habits and tissue residues. 4th phase - 72 hens divided into 4 treatments, 2 replications each: Tr. 1. Sight and sound stimulus from chicks and 6 mg dieldrin. Tr. 2. Sight and sound, no dieldrin; Tr. 3. only dieldrin; Tr. 4. no stimulus, no dieldrin. Chicks will be introduced to hens. Evaluate effect of dieldrin on acceptance of chicks.

PROGRESS: Whole-body analysis of aldrin and dieldrin for 47 birds from 16 to 92 days of age and 12 control birds from 19 to 68 days of age on treated plots was with gas chromatography. Wet-weight concentrations of aldrin and dieldrin combined were from .06 - .10 and averaged .07 ppm for control birds and .11 - 1.26 and .38 ppm for treated birds. No relationship was found between length of exposure and tissue concentrations. Highest concentratoms for both treated plots occurred in tissue of birds 61 days old. Analysis of 9 feather samples suggested uropygial secretions as one source of dieldrin residues in feathers. Growth of pheasants between 5-21 weeks of age was depressed by administration of aldrin dosages of 1.0 and 1.5 mg. Aldrin values in the brain and whole body of birds varied little (.02-.08 ppm) regardless of treatment while dieldrin values increased proportionately with treatment during the period of administration. Ten weeks after treatment was terminated brain and whole body levels of dieldrin from birds surviving the experiment were comparable to controls. Administration of 1.5 mg of aldrin in a single dosage caused death of 11 of 22, 5-week old pheasants within 48 hours. Aldrin plus dieldrin levels in these 11 birds were: brain, 2.29-4.25 ppm and averaged 2.27 ppm; whole body, 1.45-4.35 (Text Truncated - Exceeds Capacity)

SUPPORTED BY U.S. Dept. of Agriculture

4.0848, RESEARCH ON ARTHROPOD-BORNE DISEASES - II

J.W. WRIGHT, World Health Organization, *Geneva, Switzerland*

The programme to be undertaken in terms of this Grant may be divided into three major parts; 1. Toxicology of pesticides to man: This portion of the programme will be directed towards determining the mode of action of newly-developed insecticides in man, their routes of absorption, the development of methods for determining cholinesterase depression, the definition of diagnostic criteria, therapy and antidotes, and the development of measures that can be used for the protection of persons coming into contact with pesticides in public health programmes. 2. Insecticide resistance: The co-ordination, stimulation and servicing of research on the genetic, biochemical and physiological aspects of resistance and vector control and the performance of global surveys on the resistance to insecticides of the major arthropod species of public health importance. 3. Meetings and conferences: The sponsoring of scientific meetings to guide the Organization in the technical aspects of its programme and to bring together scientists involved in specific fields to review the present status of important problems.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.0849, REDUCTION OF ADVERSE EFFECTS OF PESTICIDE RESIDUES

B.J. DEMOTT, Univ. of Tennessee, Agricultural Experiment Sta., *Knoxville, Tennessee* 37916 (TEN00242)

OBJECTIVE: Study food and feed products with respect to: the location and persistence of pesticides residues in market products, the development of commercial marketing and processing techniques for the detection, removal and/or neutralization of pesticide residue effects.

APPROACH: Milks containing insecticides (DDT, lindane, methoxychlor and endrin) will be subjected to normal milk plant processes. Milk will be obtained from animals known to produce milk having a desired level of the insecticide. These milks will be subjected to heat, vacuum, steam distillation, various chemical and physical treatments in an attempt to remove and/or neutralize the residues present.

PROGRESS: Samples of milk from cows fed known amounts of furadan (Niagara 10-242) were extracted and analyzed by the method described by Bowman and Beroza (Pesticide Reviews 17:23, 1967). The excitation and emission wave lengths used by these workers were confirmed for the pesticide dissolved in acetonitrile. Fifty-two samples of milk from two cows fed up to 3 grams per day of furadan were extracted and analyzed by use of an Aminco-Bowman Spectrophotofluorometer. The concentrations of pesticide in the milk and the amounts consumed on that same day had a correlation coefficient of -0.19 for one cow and 0.01 for the other cow, indicating very little relationship between consumption and secretion of the parent compound. Complete

withdrawal of the pesticide from the feed did not cause a noticeable decline in the level of pesticide in the milk. No studies were made on metabolites of the furadan which might have been secreted in the milk.

SUPPORTED BY U.S. Dept. of Agriculture

4.0850, CHEMICAL RESIDUES IN MILK
B.J. DEMOTT, Univ. of Tennessee, Agricultural Experiment Sta., *Knoxville, Tennessee* 37916 (TEN00235)

OBJECTIVE: Determine the amount of insecticides and herbicides or their toxic metabolites which, when consumed by lactating dairy cattle, will be present in the milk. Determine how the stage of lactation and metabolic rate influence the secretion of insecticides or herbicides in milk.

APPROACH: Cows will be fed different levels of pesticides; the intake and the amount of the pesticide and its toxic metabolites secreted into the milk will be measured. Similar trials will be conducted with herbicides. Trials will be conducted on very low levels of heptachlor. Cows will be fed pesticides while dry and fattening, in early lactation and losing weight, and in late lactation and gaining weight.

PROGRESS: Efforts to improve the precision of analysis for Furadan and its metabolites in milk have continued throughout 1968. Several different extraction methods and several measurement techniques using both the halogen and nitrogen cell for the microcoulometer have been used. No measurable amounts of the Furadan parent meterial has been detected in any milk sample including milk from cows fed up to 147 ppm (feeding trial reported in 1967) Furadan in the feed for 3 week periods. Low levels of the 3-hydroxy metabolite of Furadan were detected with some extraction methods and analysis with the halogen cell in the milks from cows receiving the higher levels of furadan. However, desirable precision to clearly establish a specific level has not been obtained. In cooperative work, the Niagara Chemical Division did find levels of 0.15 ppm of the 3-hydroxy Furadan from cows receiving 2 gm of Furadan per day. These analyses were with a nitrogen cell. No residue of the parent material was detected. An additional 10 samples of milk from cows fed Furadan in the trial reported in 1967 are now being analyzed in the Niagara laboratory.

SUPPORTED BY U.S. Dept. of Agriculture

4.0851, PHOSPHOROUS INSECTICIDES EFFECT ON SULFATE FIXATION
J.T. SMITH, Univ. of Tennessee, Agricultural Experiment Sta., *Knoxville, Tennessee* 37916 (TEN00234)

OBJECTIVE: Determine effect of organo-phosphorous insecticides on the fixation of sulfate by mucopolysaccharides. Develop a screening test for the relative toxicity of different organo-phosphorous insecticides utilizing the sulfate fixation reaction.

APPROACH: Selection littermate albino rats raised to maturity, 250-300 g, on Purina lab chow will be given graduated small amounts of an organo-phosphorous insecticide. They will then be given a subcutaneous injection of Na(2)S O(4) in saline; aftet 24 hours the animals will be sacrificed and their rib cartilage removed and stored frozen. The mucopolysaccharides will be isolated from the cartilage and the specific activity of their ester sulfer determined. Different organo-phosphorous insecticides will be administered and their effect on sulfate fixation compared with their effect on cholinesterase activity.

PROGRESS: Studies using S-malathion have shown no significant difference in the absorption of malathion administered by stomach tube or fed in diet. A pilot study indicated that the rate of absorption probably causes the difference in toxicity. The specific activity of the blood of rats given S-malathion by stomach tube reaches a peak within the first hour after administration. During a 3-day study, this peak increased in intensity each day and tended to occur earlier. The specific activity of blood of rats fed S-malathion in diet indicated a steady rate of absorption. Malathion intoxication may cause a decrease in membrane mucopolysaccharides as indicated by determination of the mg hexosamine/mg N(2) in mitochondria and nuclei of controls and rats given malathion. Previous studies using S have shown a mobilization of sulfate in malathion-treated rats. These data have been confirmed by determining the mg sulfur as sulfate/mg of dried lung and brain. Many of the previous investigations using malathion have been repeated with the more toxic organophosphorus insecticide, parathion. The levels of parathion selected did not cause a decrease in sulfate fixation as did malathion nor did it cause a mobilization of sulfate into excreta.

SUPPORTED BY U.S. Dept. of Agriculture

4.0852, PRELIMINARY PESTICIDE STUDY
V.G. HENRY, State Game & Fish Commission, *Nashville, Tennessee* 37203

Objectives: To conduct preliminary investigations as to the most feasible method and procedure to obtain overall pesticide study objectives.

Procedures: 1) Review literature on pesticides--wildlife studies. 2) Consult with knowledgeable personnel concerning project plans and procedures. 3) Based on the results of the above procedures and the feasibility of the study, design the investigative study itself concerning species to be monitored, physiographic regions concerned with, number of monitoring stations, number of samples to be collected per station, methods of collection of samples, analysis of samples, and evaluation of results. 4) Prepare project Federal Aid documents.

4.0854, ENVIRONMENTAL MUTAGENESIS TESTING
J.G. BREWEN, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

Work is being done to develop a meaningful assay system by which potential environmental mutagens can be tested on human cells. To this end we have concentrated our efforts toward the development of a host- mediated-assay system. Human lymphocytes are placed in a diffusion chamber consisting of millipore filters and this chamber is implanted into the peritoneal cavity of any laboratory animal. The animal can then be treated with any compound through any of several means of exposure (feeding, inhalation, injection, etc.). It is also possible to treat the animal prior to implantation of the chamber. In any case, the chambers can be removed three days after implantation and cytogenetic preparations made from the cells.

Results: Excellent cytogenetic preparations hsve been obtained from this technique and known chemical mutagens have been tested. Typical chromosomal aberrations have been seen in the implanted cells when the host animal was exposed to a known mutagenic agent.

SUPPORTED BY U.S. Atomic Energy Commission

4.0855, ENVIRONMENTAL MUTAGEN INFORMATION CENTER (EMIC)
H.V. MALLING, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

The primary goal of the Environmental Mutagen Information Center (EMIC) is to accululate, digest, tabulate, store, and disseminate all pertinent information concerning new compounds in the human environment which have been reported to be mutagenic since January 1969. It has been known for many years

that ionizing irradiation can cause genetic damage, and the need for appropriate protection has been widely recognized. Information Centers were formed to facilitate communication between scientists and from scientist to the public about the safe handling of ionizing radiation. Some chemicals, however, may be more dangerous to the genetic health of human beings than radiation. This problem is now being recognized by the public and a part of the scientific community, and this led to the formation of the Environmental Mutagen Society (EMS). Information on the mutagenic action of chemicals can appear in most Life Science Journals. This literature area, which requires constant monitoring, is therefore very wide. The EMS considered therefore establishment of an Information Center in this field extremely necessary. Our Information Center is counseled by two distinct but overlapping committees. One is composed of EMS members only and the other is composed of members from our funding agencies and the EMS.

Our operation began in October of 1969 and our primary efforts to date have been placed on the building of our data banks. Although our official opening date is not until September of 1970, we are already experiencing a high influx of information requests. In addition to this, we have also published literature surveys on chemical mutagens in mammals, cyclamates, and the genetic effects of LSD and related psychotic compounds. State of the art reviews were also published on mercury in our environment and on the genetic effects of pesticides.

4.0856, PRELIMINARY MONITORING OF PESTICIDES
F.A. SMITH, State Parks & Wildlife Dept., *Austin, Texas* 78701

Objective: To determine the levels of mercury, dieldrin, and DDT and metabolites in chukars, pheasants, deer, waterfowl, and fish collected from various areas of Utah.

Procedures: 1. Collect chukars, pheasants, deer, waterfowl, and fish from various areas of the State. 2. analysis. 3. Analyze samples. 4. Determine extent of pesticide use in sample areas. 5. Evaluate and report results.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0857, NUTRITION AND PROPAGATION OF THE ATTWATER'S PRAIRIE CHICKEN
C.R. CREGER, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (TEX01693)

OBJECTIVE: Determine the nutritional requirements and reproductive potentials of Attwater's Prairie Chicken in Captivity.

APPROACH: This is the first attempt to propagate Attwater's prairie chicken (an endangered species) in captivity. Birds will be obtained from the wild and attempts at reproduction will be made by forced matings and artificial insemination. Birds obtained from such matings will be used to determine their nutritional requirements for protein, energy, vitamins, and minerals. In addition, studies concerning the effect of herbicides and pesticides on reproduction will be made.

PROGRESS: Project includes the nutrition, propagation, genetic makeup and pesticide effects of the Attwater prairie chicken. The Attwater prairie chicken is susceptible to and readily contracts blackhead disease, aspergillosis and enteritis. Other birds have also died of trichostrongyles and Tetrameres americanus. We have succeeded in formulating a breeder diet that maintains the birds in excellent physical condition. All birds analyzed to date have contained varying levels of DDT. Further work was conducted with the Coturnix coturnix in order to determine the effects of pesticides on reproductive performance. Results show that there is no upper level of DDT accumulation in body tissue even when levels of 500 ppm are fed. As the pesticide increases in the diet, hatchability, fertility and egg shell thickness decrease. Since the greatest percentage of pesticides are lipid soluble, studies have been undertaken which involve chemicals that tend to mobilize fats. In this area, both inositol and choline show the most promise in the removal of pesticides from fatty tissue. Restriction of food intake will also decrease the pesticide content of tissue mainly by causing reverse fat depots to be utilized.

SUPPORTED BY Texas State Government - Austin

4.0858, MINERAL INTERACTIONS WITH PESTICIDES
H.R. CROOKSHANK, Texas A & M University System, U.S.D.A. Animal Hus. Res. Div., *College Station, Texas* 77843 (033005121346)

OBJECTIVE: Determine the effects of pesticides upon the mineral metabolism of sheep and effects of varying the mineral levels of the diet on the absorption and retention of pesticides by sheep.

APPROACH: Changes in the mineral composition of blood serum, urine and feces collected from sheep fed diets with varying levels of minerals with and without the addition of graded levels of pesticides will be determined at periodic intervals over an 80 day test period. Pesticide and/or pesticide residue levels will be determined from aliquots of these samples.

PROGRESS: Changing the Ca:P ratio in the diet of wether lambs at College Station, Texas, from 1:1 to 3:1 did not affect the elimination of ronnel and its metabolites in the urine. While certain changes were observed in the mineral composition of the urine and blood of these animals the changes were not consistent and the number of samples were not sufficiently large for a statistical study. When the same procedure was used on the urine from ewes and rams which had been given 100 mg. ronnel per kg. body weight orally, neither ronnel nor any of its metabolites could be detected indicating a possible variation (wethers vs. ewes and rams) in metabolism and excretion. The ewes consistently had more ronnel in omental fat than the rams. Four days after administration there was considerable individual variation in the levels within sexes. However, this had disappeared by day 7. The rate of disappearance from omental fat was essentially similar for both sexes. Ronnel was not found in omental fat 21 days after administration.

SUPPORTED BY U.S. Dept. of Agriculture

4.0859, EFFECT OF CHARCOAL ON PESTICIDE RESIDUES AND ON NUTRIENT UTILIZATION IN RUMINANTS
H.R. CROOKSHANK, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (033005770146)

OBJECTIVE: Determine the effectiveness of activated charcoal for reducing pesticide residues in body tissues of ruminants and to ascertain if the oral application of activated charcoal affects the availability of nutrients, nitrogen retention, growth, and efficiency.

APPROACH: Two phases of experimentation will be conducted with sheep at College Station, Texas. One phase will involve the administration of activated charcoal as part of the diet or as a drench and the determination of changes in blood minerals, carotene, protein and amino acids, urinary minerals, growth and efficiency. The second phase will include the same charcoal treatments and measurements as in phase one plus the administration and tissue analyses of ronnel. At Beltsville, ruminal fistulated steers will be used in a digestion trial to ascertain the effect of charcoal on nutrient digestibility, nitrogen balance, and ruminal environment.

PROGRESS: Mixing of activated charcoal with a ronnel contaminated feed reduced the residue levels in the omental fat to 10% of those in sheep not receiving charcoal. Oral drenches of activated charcoal did not significantly reduce the residue levels. The rate of excretion of residues at the termination of the test was not affected by continued administration of charcoal. With the exception of the animals fed only the ronnel contaminated diet during weeks 4 through 9, the growth of all groups were parallel and reflected stress situations equally. These results offer the feeder a practical procedure whereby ronnel- contaminated feeds may be utilized at a nominal cost.

SUPPORTED BY U.S. Dept. of Agriculture

4.0860, METABOLISM OF CARBAMATE INSECTICIDES
H.W. DOROUGH, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (TEX01559)

OBJECTIVE: Determine metabolic pathway of carbamate insecticides in insects, animals and plants. Compare mechanisms of activation and detoxification. Determine fate of carbamate metabolites. Compare metabolism of carbamate insecticides in susceptible and resistant insects. Determine effect synergist, and other insecticides, have on observed pathway.

APPROACH: Radiolabeled carbamates will be synthesized and characterized in the laboratory. Insects and other animals and plants will be treated. Parent compound and its metabolites extracted. Components separated by chromatographic procedures and detected by liquid scintillation counting or by radioautography. Attempts will be made to identify metabolic products and to determine their individual toxicity.

PROGRESS: The metabolic fate of the more promising carbamate insecticides has been investigated. Compounds studied in greatest detail were (a) Carbaryl (1-Naphthyl-N-Methylcarbamate, (b) Matacil (O- Isopropoxyphenyl-N-Methylcarbamate, (c) Temik (2-Methyl-2-(methylthio) propionaldehyde-O-(methylcarbamoyl)oxime) and (d) Furadan (2,3-Dihydro- 2,2-dimethyl-7-benzofuranyl-N-Methylcarbamate. In general, these toxicants exhibited the same type of metabolic pathway in mammals, insects and plants. Chemical reactions responsible for the alteration of the carbamates were hydrolysis, oxidation or hydroxylation, and conjugation of those metabolites which contained a hydroxyl group. In addition, the sulfur atom in Temik was oxidized to form the sulfone and sulfoxide derivatives. With the exception of Temik-sulfoxide, the metabolites of all the carbamates were less toxic than the parent compound. Studies of the fate of carbaryl, Temik and Furadan in dairy animals demonstrated that low levels of residues were excreted in the milk - their magnitude dependent upon the level of insecticide consumed.

SUPPORTED BY Texas State Government - Austin

4.0861, METABOLISM OF CARBAMATE INSECTICIDES

H.W. DOROUGH, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (TEX04008)

OBJECTIVE: Gather detailed information on the metabolism of the carbamate insecticides for use in relating the findings to human health and in developing more effective use of these toxicants.

APPROACH: A study of carbamate insecticide metabolism will be conducted with major emphasis on defining metabolic pathways and establishing their importance in relation to the safe use of carbamates, individually and as a group. Generally, promising new carbamate insecticides will be used to a greater extent. Whether the product under consideration be old or new, radioisotopes will be used as a basic tool in all studies where radiosynthesis can be accomplished. Both plants and animals will be used as test organisms in the metabolism work. All studies will involve the identification of metabolites and determination of their individual biological activity.

PROGRESS: Continued progress was made in defining the metabolic pathways of several carbamate insecticides in plant and animal systems. Temik and Furadan still appear to have excellent potential for becoming commercially available insecticides, although their use in some cases may be highly restricted.

SUPPORTED BY Texas State Government - Austin

4.0862, INSECTICIDE RESIDUES IN POULTRY AND EGGS

F.A. GARDNER, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (TEX01560)

OBJECTIVE: Determine the effects of feeding low levels of selected insecticides on the rate of appearance, intensity and persistence of insecticide residues in both poultry and egg tissues. Determine the effects of sex and age of bird on the rate of appearance, intensity and persistence of insecticide residues in poultry and egg tissues. Determine the effects of cooking on insecticide residue concentrations in poultry and eggs. Determine the effects of storage time and temperature on insecticide residues in poultry and eggs.

APPROACH: Selected insecticides will be added to standard farm rations and fed to chickens and turkeys of both sexes and different ages. Tissues of both meat and egg will be analyzed for insecticide residue. Cooking and storage effects will be determined. Residue build-up during treatment and residue disappearance post-treatment will be determined.

PROGRESS: Chicken broilers were fed rations containing 5 and 10 ppm of both DDT and/or chlordane for a two week period (8-10 weeks of age). All combinations of these insecticide levels were evaluated. Broilers were randomly selected for a one week withdrawal evaluation period in which rations containing 6.8, 20.6 or 48.0% protein were fed. Analysis of the data demonstrates only trace accumulation of residues in breast tissue and levels less than 1 ppm in thigh tissue. (Both of these tissues are relatively low in fat content). When DDT was fed at 10 ppm, accumulation rate of residues in fatty tissues was independent of sex. Depletion rates were not affected by dietary protein during the withdrawal period. However, feeding rations containing 5 ppm of DDT resulted in a more rapid accumulation of residues in the male than in the female. Depletion rates during the withdrawal period were increased when either the high or low protein rations were used in place of the regular 20.6% ration. A dye binding method for determining the protein content of egg white and/or egg yolk has been developed.

SUPPORTED BY U.S. Dept. of Agriculture

4.0863, TOXICITY AND RESIDUES OF INSECTICIDES AND REPELLENTS IN RELATION TO INSECTS AFFECTING LIVESTOCK

O.H. GRAHAM, Texas A & M University System, U.S.D.A. Entomology Res. Div., *College Station, Texas* 77843 (00ENTH0702460100)

OBJECTIVE: Determine toxicity of insecticides and repellents to livestock and livestock insects under laboratory and field conditions and establish residue levels of parent compounds and their metabolites.

APPROACH: Treat insects individually or in small numbers in laboratory by microdrop, sprays, or by exposure to treated surfaces to establish insecticide toxicity. Cooperate with veterinarians and biochemints to evaluate effect of toxicants on animals and to establish chemically the residues in insect and animal tissues. Chromatographic techniques will be commonly used for these determinations.

PROGRESS: In toxicity tests, diazinon, ethion, dursban, and GS- 13005 effectively controlled the turkey chigger when used at a rate of 4 lbs/acre. Toxicity of dursban to turkeys and residue studies in turkey tissues are in progress. Other elements of this work area have been reported under H0701 since facilities at College Station were incomplete through most of this reporting period.

SUPPORTED BY U.S. Dept. of Agriculture

4.0864, SYSTEMIC INSECTICIDE RESEARCH ON MISCELLANEOUS INSECTS AND SPIDER MITES OF COTTON

R.L. RIDGWAY, Texas A & M University System, U.S.D.A. Entomology Res. Div., *College Station, Texas* 77843 (00ENTC0306460100)

OBJECTIVE: Develop artificial diets for rearing such insect predators as Chrysopa. Develop more effective systemic insecticides and methods of application for control of miscellaneous insects and spider mites of cotton.

APPROACH: Rear on artificial diets Chrysopa and other predators or parasites that are tolerant to systemic insecticides, evaluate candidate systemic insecticides in the laboratory, and test promising ones in the field against miscellaneous insects and spider mites. Test new concepts in applying systemic insecticides, and test slow release formulations of systemic insecticides against various insects and spider mites.

PROGRESS: A wide range of different compacted carbon-base formulations of aldicarb were less phytotoxic in laboratory tests when placed in-furrow with cottonseed than a corn-cob formulation. Considerable differences in phytotoxicity of formulations were detected. A compacted granular formulation of aldicarb made by Great Lakes Carbon Corp. reduced phytotoxicity and extended the period of insect control in field tests when compared with the standard corncob formulation. A series of

polymeric formulations of aldicarb made of urea-formaldehyde, polyamide, polyurethane, polyvinyl chloride, cellulose acetate, and polyester were prepared and evaluated in the laboratory. A cellulose acetate formulation was the most promising slow release formulation of the series.

SUPPORTED BY U.S. Dept. of Agriculture

4.0865, POPULATION DYNAMICS OF COTTON INSECTS SUBJECTED TO INSECTICIDAL TREATMENTS
J.A. WALKER, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (TEX01270)

OBJECTIVE: Establish numbers of cotton fleahoppers necessary to reduce yield and delay boll set. Develop criteria for the initiation of insecticide programs for the fleahopper. Evaluate insecticides that are used for fleahopper control with regard to their effect on beneficial arthropods in cotton. Study the effects of insecticides on beneficial arthropods when used in area-wide treatment.

APPROACH: Populations of fleahoppers will be studied in replicated plots in dry land and irrigated cotton, relationships will be established between time, length, and magnitude of infestation and yield loss and delayed boll set. The damage potential of the immature and adult stages will be determined. Observations will be made of behavioral difference that may be induced by strains of cotton known to be resistant to the insect. The effects of the different insecticides for fleahopper control as they influence the beneficial arthropod population will be examined in replicated plot experiments in cotton. Insecticides showing the most promise for fleahopper control with minimum disruption of the beneficial arthropod population will be used in large field experimentation. The overall aim of this project is to develop a minimum insecticide program for the cotton fleahopper that lowers the pest below the economic threshold, and no more.

PROGRESS: Experiments were conducted in cotton to evaluate the effect of insecticides applied for fleahopper control on beneficial arthropods. Sulphur, Sevin, Dylox, Bidrin, Strobane-DDT, and toxaphene produced sharp reductions in populations immediately after treatment. Bidrin was the most severe. 2 weeks after treatment the less harsh materials may have regained effective predatory levels. Outbreaks of Heliothis as a result of destruction of beneficial fauna would have been most favored immediately after treatment to 10 days after treatment. Studies of Heliothis larval parasitism showed low incidence 5%. Cotton was not treated until Aug. 3 (for boll weevils) and prior to this time beneficial fauna attained populations of over 20,000 per acre. Effective biological control of Heliothis resulted from the various species of beneficial arthropods.

SUPPORTED BY U.S. Dept. of Agriculture

4.0866, EFFECT OF NITRATES AND OTHER NITROGENOUS COMPOUNDS ON TOXICITY OF PESTICIDES
R.H. SINGER, U.S. Dept. of Agriculture, Vet. Tox. & Entomol. Res. Lab., *College Station, Texas* 77843 (ADPA7-45)

OBJECTIVE: Determine the extent to which nitrogenous compounds may alter the absorption, detoxification, and excretion of pesticides in animals consequently altering the toxicity of the nitrogenous compound or pesticide.

APPROACH: Various nitrogenous compounds will be administered at varying levels to animals that receive toxic and subtoxic levels of pesticides to determine any potentiation or reduction of toxicity to the animals of either the nitrogenous compounds or pesticides or both. Chemical, enzyme, and histological studies will be made on blood, urine, and tissue specimens to determine alterations in metabolic processes and detoxification mechanisms involving the nitrogenous compounds and pesticides.

PROGRESS: Toxic doses of sodium nitrite produced peak blood levels during the first hour but methemoglobin reached its peak during the 2-4 hour post-treatment period. Cardiovascular collapse proceeded unimpeded to death. Cardiovascular collapse paralleled blood nitrite levels but did not parallel methemoglobinemia. Standard therapy of methylene blue and/or ascorbic acid was ineffectual. A vasoconstrictor, such as adrenaline, administered just before methylene blue and/or ascorbic acid resulted in prompt recovery. This is a completely new and practically useful method of treatment. With identical doses of nitrite it was found that acidosis precipitated the production of hemoglobinemia. Animals on high protein or grain diets that tend to produce acidosis are more subject to methemoglobinemia from nitrite exposure than are those on diets which preserve a normal acid-base balance.

SUPPORTED BY U.S. Dept. of Agriculture

4.0867, TOXIC EFFECTS OF AGRICULTURAL CHEMICALS ON REPRODUCTION IN ANIMALS
H.E. SMALLEY, U.S. Dept. of Agriculture, Vet. Tox. & Entomol. Res. Lab., *College Station, Texas* 77843 (ADPA7-44)

OBJECTIVE: Identify agricultural chemicals which may affect reproduction in any way. Define the damage and establish limits. Investigate mechanisms of action. Ascertain actual hazard to livestock under conditions of normal use and investigate methods of reducing the hazard.

APPROACH: Screen suspect compounds in laboratory animals and extend studies into domestic animals to determine dosage, metabolism and species differences. The effects of the compounds on male and female reproductive organs and processes will be examined as well as abortifacients, mutagenesis, dominant lethality and teratogenesis. Studies of actual hazards will be done utilizing recommended methods of use. The possibility of residual compounds being available in the human diet will also be determined.

PROGRESS: Due to severe limitations of operational funds available, this project could not be sustained during this reporting period. The project has been re-written and it is anticipated future funding and cooperative efforts will provide a base for renewed effort.

SUPPORTED BY U.S. Dept. of Agriculture

4.0868, NEUROLOGICAL EFFECTS OF PESTICIDES IN DOMESTIC ANIMALS
H.E. SMALLEY, U.S. Dept. of Agriculture, Vet. Tox. & Entomol. Res. Lab., *College Station, Texas* 77843 (ADPA7-47)

OBJECTIVE: Determination of lesions and mechanisms of neurological damage to domestic animals during and after exposure to certain pesticides.

APPROACH: Production of paralysis, or other nerve damage to be done by exposing susceptible animals to various pesticides. Characterization of damage, pathogenesis, comparative toxicities, impulse excitability or inhibition, metabolic fate, antagonism and synergism, and possible protective or therapeutic mechanisms will be studied by histopathological, histochemical, biochemical, physiological, and pharmacological methods.

PROGRESS: Paraquat, an herbicide, has been repeatedly cited as the cause of fibrosing pneumonitis in the human, almost always fatal. In comparative studies great variance of effect was noted: guinea pigs, sheep and swine reacted as does the human, hamsters died of kidney damage. Turkeys tended to be refractory. Toxicity and hazard were rather definitely differentiated in studies with turkeys. Insecticides used at 4 pounds/acre seemed rather questionable in light of the most toxic being so at 2 mg/kg. Practical (duplicating needed methods) application showed no hazard to turkeys when rates were increased up to 16-fold. (Ethion, Dursban, Supracide). Such rates provided 3-10 lethal doses/bird per square foot of pasture space. When 10 ppm each of heptachlor, BHC, p,p'-DDT and 5 ppm dieldrin were added to ruminant diets, the addition of 1% activated charcoal of plant origin reduced dieldrin residues but not the others. The addition of 5% activated charcoal to a diet containing 1000 ppm of ronnel reduced tissue residues of ronnel by 95%.

4.0869, TOXICITY AND RESIDUES OF INSECTICIDES AND REPELLENTS IN LIVESTOCK AND POULTRY
R.O. DRUMMOND, U.S. Dept. of Agriculture, Livestock Insect Laboratory, *Kerrville, Texas* 78028 (00ENTH0701461100)

OBJECTIVE: Determine toxicity of insect control chemicals and other agents to livestock and poultry; establish the extent and persistence of residues in meat, milk, and eggs; develop methods that will minimize residues.

APPROACH: In cooperation with veterinarians and chemists in coordinated approaches to the problem, study toxicity in livestock and poultry, of insect and chemical control agents, determine residue levels in various tissues by bioassay and chemical techniques. Evaluation techniques entail spray, oral, pour-on, self-application, dipping, and dust treatments of livestock and poultry. Gross toxicity, physiological effect and tissue residue studies will be evaluated through visual observation of the animals, biochemical analyses of tissues and excretion, and chemical and chromatographic analyses of meat, milk, and eggs.

PROGRESS: Calves sprayed with 0.25 or 1% emulsions of CIBA C-9491 were slaughtered 1 week after spraying. Residues in the fat averaged 5.7 ppm for the animal sprayed with the higher and 0.91 ppm for the lower concentration. Residues of ronnel and its oxygen analog were determined in the fat of beef cattle sprayed twice 2 weeks apart with a 0.25% emulsion. The highest residue found was 6.80 ppm in the fat of one animal 3 days after the 2nd treatment. The highest residue 21 days posttreatment was 0.02 ppm. Residues of Dursban and its oxygen analog were determined in the body tissues of cattle following multiple dips in 0.025% emulsions.

SUPPORTED BY U.S. Dept. of Agriculture

4.0870, LIVESTOCK DETOXICATING MECHANISMS OF PESTICIDES

J.S. PALMER, U.S. Dept. of Agriculture, Toxicological Research Lab., *Kerrville, Texas* 78028 (ADPA7-19R)

OBJECTIVE: Develop the biochemical processes occurring in livestock which alter and eliminate various pesticides, and utilize the derived information in solving the problem of chemical residues in products intended for human consumption.

APPROACH: The great variations that exist in the toxicity of organic chemical compound to which livestock, chiefly cattle and sheep, may be exposed will be investigated. Physical condition and stresses having a major role in the response of animals to these compounds. An understanding of detoxication mechanisms, and the situations in which they are utilized, will facilitate the use of chemicals that are more readily eliminated, thereby reducing the hazard to animals. To delineate the different detoxifying processes, the enzymes, metabolites, and conjugation products will be determined.

PROGRESS: The metabolism and residues of radioisotope-tagged ferbam were determined for a period of 76 hours after a sheep was treated. Quench curves for each tissue, blood, urine and feces were established at various intervals of time and autoradiograms made. Another sheep was similarly exposed to confirm these results. The effect of DDT and its metabolites on adult chickens is being studied. It includes toxicity, egg production, fertility, egg shell consistency, and residues in various body tissues. The evaluation of an insecticidal formulation of crotoxyphos as a sheep dip was made. Indications are that degradation occurs on storage, resulting in an unstable and ineffective treatment. Residual and toxicological aspects of 2,4,5-T in sheep and cattle, exposed over a 9-month period, completed. Negative results on analyses of watershed samples as to evidence of possible pollution by pesticides.

SUPPORTED BY U.S. Dept. of Agriculture

4.0871, TOXICOLOGICAL EFFECTS OF VARIOUS PESTICIDES AND OTHER AGRICULTURAL CHEMICALS ON LIVESTOCK AND POULTRY

J.S. PALMER, U.S. Dept. of Agriculture, Toxicological Research Lab., *Kerrville, Texas* 78028 (ADPA7-23R)

OBJECTIVE: Develop information on the toxicological and pathological effects of insecticides, herbicides, fungicides, and other agricultural chemicals on livestock and poultry.

APPROACH: The acute and chronic toxicologic effects of each compound will be determined in all available species as to the maximum concentration or dosage that can be tolerated. Signs of poisoning will be noted while gross and microscopic changes will be recorded when fatalities result. Photography, either still or movies, will be utilized to illustrate the signs of poisoning. Studies of the residues of these compounds in various organs and secretions will be done when indicated.

PROGRESS: Study of the toxicity of 45 dominant organic herbicides to cattle, sheep, and chickens completed. Signs of poisoning and lesions at necropsy were described. The hazard to sheep consuming vegetation treated with 2 crop insecticides was evaluated. Three organophosphorous insecticides were studied as to their oral and dermal toxicity to turkeys. These compounds, effective in control of a turkey mite on ranches during the summer, were found to vary greatly as to the degree of toxicity produced at various dosages. Two formulations of crotoxyphos, applied to young pigs, resulted in dermatosis, depressed blood cholinesterase activity, or both, after repeated dermal exposures. Recommendations were to lower concentrations used and limit concomitant physical stresses. The toxicological evaluation of 5 soil nematicides in chickens, as to degree of toxicosis produced and relative feed utilization, was accomplished. Six acaracides and 4 fungicides were tested in chickens, sheep and cattle. Oral and dermal toxicity data on 61 candidate or approved insecticides were collected in various species in cooperation with Entomology Research Division.

SUPPORTED BY U.S. Dept. of Agriculture

4.0872, BIOCHEMICAL EFFECTS OF AGRICULTURAL CHEMICALS AND CONTROL SUBSTANCE TO LIVESTOCK

F.C. WRIGHT, U.S. Dept. of Agriculture, Toxicological Research Lab., *Kerrville, Texas* 78028 (ADPA7-18R2)

OBJECTIVE: Develop the histological and histochemical changes occurring in livestock.

APPROACH: Following exposure(s) to agricultural chemical compounds, chiefly pesticides, to recognize the endogenous and exogenous toxins that are developed, and to determine the extent of harmful effects produced as the result of their presence in tissue. Studies of specific serum and tissue enzyme systems and their alterations following pesticide exposure will be correlated by histology and histochemistry. The metabolism, potentiation, and synergism of a pesticide compound as affected by other pesticides, pharmaceuticals, mineral elements, etc. will be determined. Methods will be developed for this purpose, utilizing intact animals and cultures of their cells. The gross pathological lesions produced in animals and observed at necropsy with subsequent microscopic study of tissues and cells, will be related to biochemical changes.

PROGRESS: Statistical analysis of diallate-exposed sheep over a period of 4 months was completed. Death resulted after totals of 195 to 322 gm were given. The accumulative toxic effects became apparent 3 to 7 weeks before death. The parameters of feed consumed, PCV, RBC, and Hb were affected in the sheep. Cattle, sheep and turkeys were given relatively small dosages of a mercuric fungicide daily for varying periods to relate toxicosis to tissue residues. Signs of poisoning produced, at times delayed and explosive in nature, will be related to residue analysis of liver, kidney, muscle and brain samples. The persistence of ronnel residues in cattle and sheep is being studied when phenothiazine is given as a concomitant treatment. That phenothiazine may increase ronnel metabolism, thus reducing the holding period before marketing, will be determined. Cattle were poisoned with toxic dosages of coumaphos and were treated with 2-PAM chloride or atropine for comparative purposes. At relatively large doses, 2-PAM chloride was the superior agent. As an adjunct, the effects on various blood and serum enzymes were determined in response to the toxicosis and therapeutics.

SUPPORTED BY U.S. Dept. of Agriculture

4.0873, CHARACTERIZATION OF CYTOLOGICAL RESPONSES TO TOXICATIONS OF PESTICIDES IN LIVESTOCK

R.L. YOUNGER, U.S. Dept. of Agriculture, Toxicological Research Lab., *Kerrville, Texas* 78028 (ADPA7-20R)

OBJECTIVE: Determine pathologic and cytologic changes in tissues and fluids of exposed animals and poultry, correlate relationship to the toxic process and develop pathogenesis of significant lesions.

4. PESTICIDES

APPROACH: Tissues and fluids collected from subjects exposed to chemical compounds will by laboratory procedures be examined microscopically and by analytical chemistry. Conventional and special stains and tests will be used to determine pertinent histopathological changes and histochemical reactions. Studies will be on any agricultural chemical on basis of extent of use and hazard.

PROGRESS: Microscopic tissue examination of poultry, exposed to a candidate insect chemosterilant, was made for pathological lesions. Statistical analyses of egg production, feed consumption, fertility, hatchability, and organ weights are in progress as an integral part of the study. Distribution of apholate, metepa, and tepa (injected into chicken egg yolk) and their LD(50) values in chicken embryos completed. A study of the teratogenic effects of these compounds at various dosage levels was finished with descriptions of deformities produced. Only examination of CNS and peripheral nerve tissues, to delineate neurotoxic response of sheep to an anthelminthic, remain to complete another study. Procedures for culturing bovine peripheral blood were established with chromosomal dispersions. Subsequently, the effects of various dilutions of apholate on multiplication of leukocytes were determined. Explant cultures of chicken embryo cerebella prepared for exposure to organophosphorous compounds to determine the sequence of events that occur in axons.

SUPPORTED BY U.S. Dept. of Agriculture

4.0874, TOXICOLOGIC EFFECTS OF HERBICIDE-TREATED PLANTS ON LIVESTOCK

A.E. JOHNSON, U.S. Dept. of Agriculture, Poisonous Plant Research Lab., *Logan, Utah* 84321 (ADPA7-49)

OBJECTIVE: Determine herbicidal toxicity and tissue residue in cattle and sheep from ingestion of Atrazine-treated plants.

APPROACH: Forage on stubble previously sprayed with known amounts of Atrazine will be collected daily and fed to test animals for 30 days. Samples of treated and untreated forage will be collected on 0, 3, 7, 14, 21, and 30 days post-spraying for chemical analysis to establish residue levels and dissipation rate. Daily observations will be made of bowel evacuations, behavior, and body conditions. Organ dysfunction tests, hemograms, and general physical examinations will be made weekly. At termination of the feeding period, samples of liver, kidney, fat, and muscle will be obtained for tissue residue determinations and pathology.

PROGRESS: In the process of treating tall larkspur (Delphinium barbeyi) with 2,4,5-T (2,4,5-trichlorophenoxyacetic acid) for animal experimentation, it was noted that the use of high nitrogen fertilizer (ammonium sulfate) considerably increased the efficacy of the herbicide in controlling growth of the plant. Reasons for this are not fully understood at this time. Losses of cattle from consuming this plant equal or perhaps exceed losses resulting from any other poisonous plant, and it has to date been resistant to or impractical to control by herbicide application. Any aid in eradicating this plant from problem areas is extremely important to the livestock industry of the West. No congenital deformities were produced in the lambs from ewes fed 2,4,5-T acid (2,4,5-trichlorophenoxyacetic acid) and 2,4,5-T ester (2,4,5- trichlorophenoxyacetic acid propylene glycol butyl ether ester) at 100 mg. per kg. of body weight from 14 to 36 days of gestation mixed in dried ground alfalfa and fed daily via stomach tube. Cows fed a high sodium mineral supplement were more susceptible to pulmonary emphysema following ingestion of DL tryptophane than cows receiving no supplement.

SUPPORTED BY U.S. Dept. of Agriculture

4.0875, FUNDAMENTAL BIOCHEMICAL AND BIOPHYSICAL MECHANISMS INVOLVED IN HERBICIDAL ACTION

J.L. ANDERSON, Utah State University, Agricultural Experiment Sta., *Logan, Utah* 84321 (UTA00716)

OBJECTIVE: Develop and employ a controlled system of plant material, environmental growth conditions and chlorophenoxy herbicide application which will be used on an interstate basis for fundamental biochemical studies of herbicide action. Discover the key biochemical mechanism(s) of herbicidal action through simultaneous interstate study and comparison of herbicide effects on biochemical and metabolic processes of the same types of plants studied under the same experimental conditions.

APPROACH: Utah will cooperate closely with Oregon in a study of the cytological and anatomical changes induced by chlorophenoxy herbicides and correlate these findings with changes in specific enzymes and nucleic acids resulting from their interaction with sodium 2,4-D.

PROGRESS: Ultrastructural effects of pyruvon on bean and oat chloroplasts were observed. Chloroplasts from treated plants were totally devoid of starch, became enlarged and spherical, and disintegrated as visual symptoms developed. Propachlor was found to inhibit protein and lipid breakdown in squash cotyledons. It was further shown that propachlor inhibited a sodium p-pyrophosphate ATP exchange reaction in vitro and may have as its mode of action the inhibition of amino acid activation. DCPA was found to alter parenchyma and phloem fiber cell orientation in treated tomato hypocotyls. Oblong swellings developed just above the ground level when tomatoes were grown in treated soil. Symptom expression may be conditioned by environmental conditions under which the tomatoes were grown. Vascular disruption has been observed in 2 ppm DCPA treatments, which is well within the label limits for DCPA application. EPTC effects on oat lipids were studied histochemically. It appears that treated oats tend to accumulate lipids in the seedling coleoptiles rather than translocate and utilize them elsewhere. Leaf cuticles were affected to the extent that they adhere to each other and are torn before they will separate.

SUPPORTED BY U.S. Dept. of Agriculture

4.0876, INSECT POLLINATION INVESTIGATIONS ON LEGUMES

G.E. BOHART, Utah State University, Agricultural Experiment Sta., *Logan, Utah* 84321 (UTA00310)

OBJECTIVE: Methods of increasing percentage of pollen-collecting honey bees on Utah alfalfa. Improve existing management procedures for Nomia melandri and Megachile rotundata. Introduce suitable species of alfalfa pollinators to Utah.

APPROACH: In cooperation with ARS, breed one or more lines of honey bees that have a greater tendency to collect alfalfa pollen. Study of organisms in Nomia melandri nesting sites inimical to larvae in cooperation with University of California. Increase 'take' of adult Nomia melandri introduced to a new nesting site. Comparisons of mortalities of eggs and larvae of Megachile rotundata in various nesting materials exposed to various conditions of temperature and humidity. Studies of foraging behavior of Megachile rotundata to determine placement pattern for field shelters. Exploring suitable areas for alfalfa pollinators of potential value to Utah.

PROGRESS: Studies were continued on the high alfalfa pollen collecting lines of honey bees. The high APC had the highest percent of alfalfa pollen collection, the hybrid had only slightly higher percent of alfalfa pollen collectors than the 'B' line and was intermediate, and the low APC line was low as usual. Studies on the propagation of the drone fly, Eristalis tenax, were conducted in the flight room and in the greenhouse to obtain flies for field releases and to develop suitable rearing methods. Studies were conducted on the mortality of adults and immatures of the alfalfa leafcutter bee exposed to plants treated with Dibrom, Dylox, and Cygon. Survival of immatures was not affected. Adults live longer in cages with untreated than with treated plants. There was more nest abandonment in Dibrom treatment than with Dylox, but bees in Dibrom cages made more new nests after treatments than they did in Dylox cages (27% vs. 3%). The number of cells/bee increased from 1.27 to 1.74 after Dibrom treatments and decreased from 1.9 to 1.04 after Dylox treatments. Cygon applied 3 weeks before exposure to bees had no apparent affect.

SUPPORTED BY Utah State Government

4.0877, PESTICIDE AND POLLUTANT TOXICITY AND INTERACTIONS IN BEES

W.A. BRINDLEY, Utah State University, Agricultural Experiment Sta., *Logan, Utah* 84321 (00ENTC10154701CA)

OBJECTIVE: Research on the effect of insecticides and other synthetic chemicals and their interactions on bee pollinators and develop methods to increase the resistance of pollinators to insecticides.

APPROACH: A chemical method of increasing pesticide resistance in bee pollinators by enzyme induction and other means will be sought. The toxicity of insecticides to the honey bee, Apis mellifera, the alfalfa leaf-cutter bee, Megachile rotundata, the alkali bee, Nomia melanderi, and other bees collected in the field will be studied. Determine the effect of interactions between insecticides and environment pollutants upon bee pollinators by biological assay and physiological tests. Develop a non-lethal in vivo test to survey bee populations for pesticide-resistant individuals.

SUPPORTED BY U.S. Dept. of Agriculture

4.0878, BIOLOGICAL CONTROL AGENTS TO REPLACE OR SUPPLEMENT PESTICIDES TO CONTROL PHYTOPHAGOUS ARTHROPODS

D.W. DAVIS, Utah State University, Agricultural Experiment Sta., *Logan, Utah* 84321 (UTA00679)

OBJECTIVE: Development of principles of insect pest management for regional environmental improvement. Multistate conservation and augmentation of biological control agents through environmental manipulation. Recognition and experimental interchange of entomophagous bio-types for improved biological control.

APPROACH: Replicated field plots using cultural practices and insecticides will be evaluated both for effects on the alfalfa weevil and on predators and parasites. Laboratory rearing and field releases of new alfalfa weevil parasites will be tried. Biological studies of weevil parasites and predators will be continued.

PROGRESS: The alfalfa weevil insecticide plots discussed under Project 622 were evaluated for their effects on beneficial insects, particularly the weevil parasite Bathyplectes curculionis. All insecticides, except Imidan, seriously reduced the adult parasite numbers when applied during periods of adult activity. The parasites usually returned rapidly, especially with the short-lived insecticides. Furadan, which was the most effective material against the alfalfa weevil, unfortunately was most toxic to the parasites. The destruction of adult parasites is not always reflected by the percentage of parasitism. The total numbers of weevil larvae are less, the parasite adults usually return rapidly, and the improved alfalfa growth following treatment appears to attract the parasites. As a result there was frequently an increase in percentage parasitism in treated plots over the checks. In 1967, and again in 1969, several species of new alfalfa weevil parasites were released in Utah. In spite of numerous attempts at field recovery, there is no evidence of successful establishment of these parasites in Utah.

SUPPORTED BY U.S. Dept. of Agriculture

4.0879, CONTROL OF MITES AND INSECTS ON FRUIT TREES

D.W. DAVIS, Utah State University, Agricultural Experiment Sta., *Logan, Utah* 84321 (UTA00431)

OBJECTIVE: Study the biology and importance of selected species of mites and insects found associated with fruit trees in Utah. Study integrated control of orchard pests, with special emphasis on involving the mite predators. Evaluate available insecticides and acaricides in the control of orchard insects and mites, especially in cases where present control measures are insdequate. Investigate techniques, other than chemical, which can improve or displace the current practices.

APPROACH: Laboratory and greenhouse studies of the major predators of spider mites, initially the major attention has been devoted to Typhlodromus occidentalis. Replicated field plots for the control of orchard pests and evaluating the effects of the spray program on beneficial insects. Laboratory bioassay evaluation of pesticides.

PROGRESS: Replicated acaricidal plots were located at North Salt Lake City in McIntosh apples. Plictran followed by Omite and Carzol were the three best materials for the control of mixed populations of McDaniel and two-spotted spider mites. These three materials not only controlled the harmful mite species, but also allowed the beneficial predatory mites to survive and extend the effectiveness of the acaricides. Six orchards in northern Utah were studied for the third consecutive season in an attempt to get integrated control of orchard pests on a firm footing. In four of the orchards, the results have been very good to excellent. In one orchard the results have been marginal, and in the sixth only fair at best. The less satisfactory results seem to be associated with orchards having problems with two-spotted mites rather than McDaniel mites. Mesurol was used in one orchard as the sole insecticide. Mite and codling moth control were good, but there was a serious build-up of woolly apple aphids. The pear psylla and the oriental fruit moth were found in Utah for the first time during 1969. Considerable time was spent late in the summer evaluating these problems.

SUPPORTED BY U.S. Dept. of Agriculture

4.0880, BIOLOGY AND CONTROL OF THE ALFALFA WEEVIL

D.W. DAVIS, Utah State University, Agricultural Experiment Sta., *Logan, Utah* 84321 (UTA00622)

OBJECTIVE: Evaluate predators and parasites of alfalfa weevil, and determine effects of insecticides on these beneficial insects. Evaluate insecticides and insecticide timings in weevil control. Study life history of alfalfa weevil in Utah. Study all species of weevils associated with alfalfa.

APPROACH: Apply replicated field plots of insecticides and evaluate effects on both weevils and the beneficial insects. Study in detail the feeding habits of selected predators and parasites of the weevil. Study the seasonal life history and behavior of the alfalfa weevil both in the laboratory and in the field.

PROGRESS: Three series of replicated field tests of insecticides were studied. They were evaluated both for alfalfa weevil control and for effects on beneficial insects, which is reported under Project 679. All of the 1969 studies were timed for larval control about 2-3 weeks before the first cutting. By far the best results were obtained with Furadan, which showed 99% weevil control at harvest. Several other materials showed between 89% and 93% control: Imidan, Baygon, ethyl parathion, methyl parathion, Geigy 13005, Sevithion, and Guthion. Most of the insecticides began to lose their effectiveness after 10-14 days, and by 21 days the weevil populations increased very rapidly. Very few insecticides can be used within less than 14 days of alfalfa harvest. This means that pesticide applications must be made during the period of 14-21 days of cutting. Studies of weevil biology and behavior were continued.

SUPPORTED BY Utah State Government

4.0881, THE TOXICOLOGICAL ACTION OF ORGANOPHOSPHATES AND CARBAMATES

D.A. GREENWOOD, Utah State University, Agricultural Experiment Sta., *Logan, Utah* 84321 (UTA00672)

OBJECTIVE: Evaluate the use of chicken eggs and chickens in toxicity studies of pesticides, and of chicken eggs and mice in studies of air pollutants. Determine the biological effects of feeding different elevated levels of Malathion and Carbaryl for short feeding periods. Determine the biological effects of feeding elevated levels of selected carcinogenic polynuclear aromatic hydrocarbons to mice for short periods.

APPROACH: Mature White Leghorn chickens (312 laying hens, 65 roosters) will be allotted at random to 13 pens (10' x 10') and fed laying mash to which various levels of various pesticides will be added for a period of three weeks. Eggs will be collected daily and incubated to determine hatchability and teratogenic effects. At the end of the three week period the birds will be sacrificed and tissues taken for chemical and histopathological studies. 132 adult virgin female mice, 5 to 7 months of age, will be used to determine the effects of various levels of pesticides administered to them. They will be divided into 5 groups and fed various diets, with a control group serving as the 6th group. After 21 days the animals will be examined for various symptoms.

PROGRESS: Experiments were conducted to determine the biological effects (blood cholinesterase, body weight, egg production and hatchability, development of embryos, and storage of

pesticides in the tissues of sacrificed adult birds) of feeding a laying mash alone and mash to which pesticides, Malathion and Carbaryl, were added singly and in combinations at levels of 75, 150, 300, and 600 ppm to mature chickens for three weeks. Mature White Leghorn chickens, 312 laying hens and 65 roosters, were weighed and allotted at random to 13 lots (24 hens and 5 roosters per lot). Twelve of the 13 lots were fed laying mash containing pesticides at the various levels indicated. Fresh water was always available. These studies indicated that feeding elevated levels (15-600 ppm) of Malathion and Malathion plus Carbaryl to laying White Leghorn hens and roosters for three weeks decreased the blood cholinesterase and hatchability of eggs. The percentage of deformed embryos tended to increase as the concentration of the pesticides increased in the diet. Malformations of the skeletal structures, eyes, edema of neck and head were among the deformities noted.

SUPPORTED BY Utah State Government

4.0882, BRAIN LESIONS, BEHAVIOR CHANGES AND PESTICIDE RESIDUES
R.P. SHARMA, Utah State University, School of Agriculture, *Logan, Utah* 84321

Studies in this project are proposed to relate dieldrin residues in brain, behavioral changes caused by these residues, and associated biochemical lesions in the brain. To explore the possibility of such relationships, studies will first be conducted in ducks, maintained at this institute for a long time on various dietary levels of dieldrin. Alteration in normal behavior of ducks has been related with pesticide residues and controlled studies to correlate dieldrin and behavior are in progress.

Changes in behavioral pattern may have a definite biochemical or molecular basis. Certain behavioral changes have been associated with alteration in the levels of certain chemicals, specifically serotonin and catecholamines, in different parts of the central nervous system. In the present studies, the changes in these chemicals in the brain would be determined along with the pesticide residues and will be correlated with the changes in behavior. The catecholamines and serotonin in brain will be determined spectro-fluorometrically and dieldrin will be measured by electron-capture gas chromatography. The studies will then be extended to laboratory mammals. In these animals biochemical changes in the nervous system should be indicative of deleterious effects of pesticide residues. It is expected that such studies will help us conclude whether or not the pesticide residues have any influence on mental health, and if they do, how these changes are brought about at the cellular level.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.0883, RESIDUES OF SELECTED PESTICIDES IN PLANTS, ANIMALS AND THE PHYSICAL ENVIRONMENT
J.C. STREET, Utah State University, Agricultural Experiment Sta., *Logan, Utah* 84321 (UTA00603)

OBJECTIVE: Develop a more comprehensive understanding of metabolic interaction phenomena between organochlorine pesticides and other pesticides or significant food additives. Various specific objectives within this general aim will be pursued as follows: Investigate the detailed changes in metabolism of pesticides produced in vivo by microsomal enzyme inducing agents; investigate additive and competitive relationships among organochlorine pesticides active both as microsomal enzyme inducing agents and as toxic substrates, in vivo; investigate structure-activity relationships among hepatic enzyme-inducing pesticides and also the types of detoxication enzymes affected; investigate key nutritional factors and physiological aspects related to the above interaction phenomena.

APPROACH: The indicated investigations will be conducted using laboratory animals, principally rats and guinea pigs. Chlorinated cyclodiene metabolism by animals stimulated with various inducing agents will be studied with labeled radiocarbon compounds. Additional DDT analogues and related compounds will be examined for correlation between molecular characteristics and enzyme induction. Efforts will be made to evaluate functions of ascorbic acid and vitamin A in the induction of liver microsomal enzymes by organochlorine pesticides.

PROGRESS: Study of organochlorine pesticide interactions has continued. Chlorinated biphenyls (Aroclors) were strongly active in inducing microsomal enzymes. Dieldrin metabolism and storage were markedly affected by treatment of rats with these materials. Various phenylurea herbicides were found to have low including potency with qualitatively different enzyme responses. A study of DDT metabolism in rats indicated that DDT analogues reduced DDT storage but chlorinated cyclodienes were scarely active. A general requirement for ascorbic acid to support both microsomal hydroxylation activity and its induction by dieldrin has been established. The inducing potency of DDT and dieldrin in the rat and threshold dosages required were partly dependent upon characteristics of the diet. The inbred albino laboratory rat is atypically very sensitive to the inducing action of DDT. Previous studies with large mammals (cattle, sheep and dogs) led to the same conclusion.

SUPPORTED BY U.S. Dept. of Agriculture

4.0884, THE METABOLIC FATE OF AN ORGANIC PHOSPHATE INSECTICIDE (GS-13005) WHEN FED TO DAIRY CATTLE
J.T. HUBER, Virginia Polytechnic Institute, Agricultural Experiment Sta., *Blacksburg, Virginia* 24061 (033106970149)

OBJECTIVE: Determine the residues in milk and tissues of dairy cattle resulting from feeding on GS-13005; determine the physiological effects of feeding GS-13005 to young ruminants; study the effects of dietary variables on the rate of rumen degradation of the insecticide.

APPROACH: The rate of GS-13005 degradation and identification of metabolites will be studied in rumen contents, in fistulated steers and in vitro. Physiological reactions of calves fed GS-13005 at various levels will be studied. Occurrence of the insecticide and its metabolites in blood and tissues of these calves will be determined. Lactating cows will be fed GS-13005 at four levels to determine the rate of insecticide degradation, accumulation and excretion in the milk. The persistence of GS-13005 in field sprayed hay and silages will also be studied.

PROGRESS: Degradation of GS-13005 was shown to occur in ensilage, baled hay and by rumen microorganisms in vitro. Disappearance of GS- 13005 from the rumen in vivo far exceeded the rate of in vitro degradation indicating that from a practical standpoint, breakdown in the rumen environment is relatively unimportant. Most important is the absorption phenomenon which was verified by rates for appearance of radioactivity into the blood of cows and the relatively small output of isotope in the feces. Considering GS-13005 for weevil control, it would appear to be a safe chemical. Levels expected on a crop two weeks post-spraying would not exceed 1 ppm. Levels adminintered in this study were often 30-50 times that. Due to additional storage losses and the demonstrated ability of the bovine to metabolize relatively high levels (30 ppm or 1 mg/kg) without accumulation in tissue or excretion in milk, this chemical control would appear satisfactory for common use.

SUPPORTED BY U.S. Dept. of Agriculture

4.0885, ORGANIC PHOSPHATE RESIDUE IN DAIRY COWS
C.E. POLAN, Virginia Polytechnic Institute, Agricultural Experiment Sta., *Blacksburg, Virginia* 24061 (VA-030550)

OBJECTIVE: Determine the physiological effect and extent of catabolism of GS-13005 in bovine. Determine the rate of degradation of GS-13005 in feedstuffs and in the rumen environment. Measure the extent of accumulation of phosphate residues in tissue and excretion in milk if any.

APPROACH: Administer varying levels, up to a toxic level, of GS- 13005 to young bulls. Blood was sampled routinely and cholinesterase activity established. Tissues from animals that died and those slaughtered were analyzed for organophosphorus residues. Cows were administered GS-13005 by capsule and in a second study GS-13005 was applied in the field to uncut hay. Milk was sampled periodically for residues analysis. Cows at all treatment levels were slaughtered and certain tissues analyzed for phosphate residues. Intake and productive performance was measured on all animals. The rate of disappearance of GS-13005 was

determined in baled hay, ensilage, in vitro rumen incubations and from the intact rumen. Ring labeled GS-13005 was administered to two lactating cows and the metabolism of the compound and routes of excretion were studied in detail. Metabolic products were examined by extraction techniques and thin-layer chromatography.

PROGRESS: Degradation, excretion and metabolism of GS-13005 (G), were studied in two lactating cows. Cow 290 received oral doses of 1 mg/kg B.W./day of G for 30 days. On day 31 she was dosed with 1.7 mg/kg of carbonyl - C-G. Cow 282 received a similar dose of radioactive G but without prior pesticide administration. Radioactivities in CO(2), urine, feces, and milk for cow 290 and 282 were, respectively, 16, 38, 6, 1; and 51, 43, 4, and 1% of dose. Peak urinary and serum radioactivity was observed between 4 and 6 hr, then decreased to negligible levels in 36 hr. Autoradiography of TLC and GLC indicated G in milk of cow 290. Following conclusion of the above experiments Esser et al. reported a sulfoxide and sulfone to be the principal metabolic products of G in the rat. To test the occurrence of these compounds in the milk, a cow was given 1.25 mg of G/kg bdwt. daily. On day 17, she was given 1.7 mg/kg of labeled compound. Milk radioactivity as percentage of dose of 0-12 and 12-24 hrs was respectively 1.2 and 0.7%.

SUPPORTED BY Virginia State Government

4.0886, EFFECTS OF DIETARY PROTEIN ON THE METABOLISM OF HEPTACHLOR IN THE RAT

R.E. WEBB, Virginia Polytechnic Institute, Agricultural Experiment Sta., *Blacksburg, Virginia* 24061 (VA-0616089)

OBJECTIVE: Determine the influence of the level of dietary protein on the conversion of heptachlor to heptachlor epoxide and the distribution and excretion and metabolites; effects of dietary protein quality on the metabolism, distribution, and excretion of heptachlor; and the influence of protein nutriture on pesticide-pesticide interactions.

APPROACH: Little attention has been directed toward assessing the effects of nutritional status of the animal or individual on the toxicity of pesticides. This assessment should be considered in the evaluation of safety of pesticides. Since protein malnutrition is wide- spread in certain areas of the world, the effects of dietary protein level and quality on pesticide toxicity will be studied. Heptachlor as an example of the chlorinated cyclodienes, a group known to result in residue problems, has been selected for study under imposed variations of protein nutriture.

PROGRESS: Having established the effects of dietary protein on the acute toxicity and metabolism of heptachlor and its epoxide, studies were initiated to determine the in vitro effects by measuring the liver levels of microsomal epoxidase activity in rats fed 5, 20 and 40 dietary casein. Results show that the maximum velocity of the low protein fed rats was considerably lower than for other groups. This finding supports previous suggestions of an impaired ability of the low protein rats to convert heptachlor to the toxic metabolite.

4.0887, CARCINOGENESIS BIOASSAY RESOURCE FOR FEEDING TESTS IN RODENTS

G.C. HOLSING, Hazleton Laboratories, *Falls Church, Virginia* 22046 (NIH-70-2209)

Independently and not as an agent of the Government, the Contractor shall exert its best efforts to perform carcinogenesis bioassay feeding tests in mice, rats, or other rodents of pesticides and other environmental chemicals selected by the Project Officer. In performance of this project, the Contractor will: 1. Procure chemicals, analyze for amount and types of impurities, determine stability and purify when indicated by the Project Officer. 2. Conduct subacute oral toxicity studies to determine maximum tolerated dose for use in the long-term study. 3. Perform lifetime feeding tests for carcinogenicity studies in groups of 50 mice and 50 rats of each sex at two dose levels. Appropriate positive and negative controls will be used as indicated by the Project Officer. 4. Maintain adequate check of the diet regarding stability of test compound. Observe and record weight gain and health of animals, and acceptance of food; 5. Sacrifice moribund animals and perform complete autopsy on all animals including histologic examination of all indicated target tissues as well as tumors at other sites; 6. Tabulate data on forms provided by The National Cancer Institute. Results will be evaluated for significance.

4.0888, TOXICOLOGY OF CANDIDATE INSECT CHEMOSTERILANTS OR ATTRACTANTS

W.A. KNAPP, Hazleton Laboratories, *Falls Church, Virginia* 22046 (00ENTM02084908CO)

OBJECTIVE: Obtain information on mammalian toxicity of compounds under investigation as insect chemosterilants, attractants, or other new types of insect control chemicals.

APPROACH: Determine acute and subacute oral toxicity to male and female rats of experimental insect control chemicals to be specified and supplied by Entomology Research Division chemists. Make 2-year toxicological evaluation of 2 experimental insect chemosterilants including minimum subacute dermal toxicity to male and female rabbits, subacute dietary administration to male and female rats, and effects on reproduction in rats.

PROGRESS: Dermal and acute toxicities of tepa and hempa were determined on rabbits and rats, respectively. Tepa in 2-generation reproduction and 90-day incubation studies caused decreased fertility and increased thyroid size and activity. Hempa caused increased respiratory disease and decreased fertility as a secondary effect. No increased incidence of neoplasia was found. Acute toxicities for 4 other compounds were also determined.

SUPPORTED BY U.S. Dept. of Agriculture

4.0889, PESTICIDE RESIDUES INGESTED BY FINISHING AND REPRODUCING BEEF CATTLE

K.P. BOVARD, U.S. Dept. of Agriculture, Beef Cattle Research Station, *Front Royal, Virginia* 22630 (033003870149)

OBJECTIVE: Determine the rate and level of accumulation of pesticide residues in pregnant beef cows, cows nursing calves and fattening steers while consuming pesticide contaminated feeds; rate of dissipation when the contaminant is removed; and transmission from cow to calf placentally or by infestion of milk.

APPROACH: In the first experimental phase, 20 yearling steers were self-fed a fattening ration for 189 days. The ration for 5 steers (lot 1) contained 0.15 p.p.m. total heptachlor residue and that for 15 steers contained 0.23. Perianal fat samples were collected from all 20 animals at the beginning and end of this period. During the second phase lot 1 continued to receive the same contaminated ration ad libitum. The remaining steers were allotted as follows: lot 2, residue- free ration, ad libitum; lot 3, residue-free ration containing protamone, ad libitum; lot 4 residue-free ration, limited to maintenance. Perianal biopsies were taken periodically for 18 months.

PROGRESS: Beef cows in confinement received recommended amounts of a ration containing 0.4 ppm heptachlor and heptachlor epoxide (HHE) during the last 3 months of gestation and for 6 months postpartum. Periodic perianal fat biopsies indicated that: (1) Cows receiving the contaminated ration accumulated HHE at 0.01 ppm per day through the fifth month postpartum levels reaching 1.5 ppm in their external fat. During the sixth month postpartum, a decrease at about the same rate was seen, calves' contamination followed that of their dams. (2) Cows receiving residue-free feed throughout the study showed no contamination, nor did their calves, and (3) Cows receiving heptachlor- contaminated feed rapidly became contaminated. Once this insecticide is absorbed, it is very slowly dissipated by contaminated cattle. No physical symptoms of toxicity were seen in cows or calves.

SUPPORTED BY U.S. Dept. of Agriculture

4.0890, METABOLISM OF PESTICIDES BY BEEF CATTLE CONSUMING FEEDSTUFFS PRODUCED IN THE APPALACHIAN AREA

B.M. PRIODE, U.S. Dept. of Agriculture, Animal Science Research Div., *Front Royal, Virginia* 22630 (033001637014 9)

4. PESTICIDES

OBJECTIVE: Study distribution of tissue residue and the chemistry of pesticides in beef cattle for the ultimate protection of the animal and the consumer.

APPROACH: Techniques used to investigate the metabolism of pesticides by beef cattle will include cannulation of the portal and ruminal veins to estimate rate of blood flow and pesticide absorption; quantitative collections of feces, urine and respiratory gases; location and concentrations of residues in fat, muscle, blood and milk; and measurements of the general physiological status of animals being exposed to pesticides now in use or about to be used. At Front Royal, Virginia, studies will be oriented toward feedstuffs used to maintain the beef brood cow during the winter.

PROGRESS: Eight lots of four pregnant beef cows, at Front Royal, Va., each received wet apple pomace silage and protein supplement in confinement from 6 months gestation through two months post partum. Two samples of apple pomace were taken from each of 14 truckloads at delivery in October. The following pesticides and mean contamination (ppm) were found: DDT, 2.27; DDE, 0.15; TDE, 0.12; Kelthane, 1.43; Acaralate, 0.50; Ethion, 0.32; tedion, 1.3; parathion, 0.26; and delnav, 0.21. Among the first seven, highly significant (P of .01) differences existed among trucks for all except kelthane and BHC. Among 33 calves born, 6 of 8 whose dams receives CSM survived; 4 or 8 whose dams received CSM and urea survived: and 3 of 17 whose dams received urea survived. The balance were stillborn, or died soon after birth. The implication of the combination of apple pomace, its pesticides, and urea is clear-cut. Further studies are planned.

SUPPORTED BY U.S. Dept. of Agriculture

4.0891, INHIBITORY EFFECT OF DDT IN ATPASE ASSAY MIXTURES

C.B. CROSTON, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Cook, Washington*

Homogenates will be made of fish tissues, particularly liver and muscle, and will be assayed for adenosine triphosphatase activity. Various amounts of DDT will be added to the assay mixtures to measure the inhibitory effect. A few percentages of liquids having a wide range of solvent powers, such as dimethylformamide and dimethylsulfoxide, will be included in the assay mixtures to attempt increased dissolution of the DDT. The amounts of inhibition will be compared to distinquish different ATPases of cellular fractions, tissues and fish species.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0892, PESTICIDE MONITORING

W.D. BRUNSON, State Dept. of Game, *Olympia, Washington* 98501

Project: Pesticide monitoring.

Objective: To determine the levels of pesticide residues in fish hatchery water supplies, natural waters, and fish food.

Procedures: Samples will be collected statewide and transported to the Western Fish Disease Laboratory, Bureau of Sport Fisheries and Wildlife, Seattle, for preparation, extraction, and gas chromatographic analysis of chlorinated hydrocarbon pesticide residues.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0893, EFFECT OF PESTICIDE RESIDUES ON GAME FISH POPULATIONS

W.D. BRUNSON, State Dept. of Game, *Olympia, Washington* 98501

Project: To determine the effect of pesticides on game fish populations.

Objective: To determine the timing in respect to life cycle and the method by which pesticides accumulate in immature fish and the physical charges which result from this accumulation.

Procedures: Monitoring will be accompanied by microscopic examination.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0894, ELIMINATE OR REDUCE EFFECTS OF PESTICIDE RESIDUES

W.D. BRUNSON, State Dept. of Game, *Olympia, Washington* 98501

Project: To eliminate or reduce effects of pesticide residues on game fish.

Objective: To eliminate or reduce the effects of pesticide residues on game fish in trout hatcheries.

Procedure: Activated carbon filter will be installed and special pesticide free diets (if available) will be fed selected lots of fry to determine if mortalities can be reduced by this method. Filters will be experimented with at the Game Department's Columbia Basin Hatchery which has a record of mortalities indicating that the major cause may be the presence of DDT and its metabolites. Dietary experiments will also be conducted at the Basin Hatchery.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0895, CONTROL OF INSECTS AND MITES ON HOPS

W.W. CONE, Washington State University, Agricultural Experiment Sta., *Pullman, Washington* 99163 (WNP0184?)

OBJECTIVE: Test and evaluate insecticides and acaricides for control of insects and mites on hops. Investigate the effect of toxicants on beneficial predatory organisms. Determine the inherent natural resistance of hop variety selections to two-spotted mite infestation.

APPROACH: Insecticides and acaricides will be tested for control of two-spotted spider mites and insect pests on hops. Samples of green and dried hops taken for residue analyses. Determine the abundance of beneficial predatory mites and coccinellid beetles in hop yards; and if toxicants presently in use have an effect on their abundance. Roots from clones of disease resistant hop lines will be planted and evaluated for resistance to mite attacks.

PROGRESS: Fourteen unregistered acaricides were tested in replicated plots of hops for control of two-spotted spider mites and hop aphids. Carzol, Azodrin, Plictran and Omite were effective for mite control. Malathion must be combined with each compound except Azodrin to provide aphid control. Residue analyses are being conducted for all except Plictran. TH-427, TH-367, Bayer 68138, and Geigy 13095 show promise for future testing against mites. Torak, Geigy 19851, CIBA 9491, Cba 2307, Lovozal and superior oil were ineffective for mite control. Lovozal tested as a 40% wettable powder was phytotoxic to hops. Kelthane (dicofol) used on the same hills for four years failed to control mites. Percent control was 96.4, 93.1, 73.3 and 0 for 1966 1967, 1968 and 1969, respectively. Disyston, Temik, Thimet, Bayer 68138 and Hercules 17413 were tested for systemic activity against mites and aphids. Temik was the only promising compound. Bioassay of ether or methylene chloride extracts of quiescent deutonymphs indicate 5 to 15% male reponse at dilutions of .0005 female equivalents. Site of pheromone production appears to be mid-dorsal area. Males are attracted soon after onset of quiescence and may hold until emergence (36-48 hours). Pheronome appears to have low volatility, good persistence (over 100 hours), and may serve as an arrestant instead of an attractant.

SUPPORTED BY Washington State Government - Olympia

4.0896, BIOLOGY, ECOLOGY, AND CONTROL OF INSECT AND MITE PESTS OF APPLE

S.C. HOYT, Washington State University, Agricultural Experiment Sta., *Pullman, Washington* 99163 (WNP01477)

OBJECTIVE: Study the effect of feeding by mites on fruit quality and yield. evaluate the effects of cultural practices and pesticides on pests and on predator-prey relationships: study in detail the population dynamics of mites.

APPROACH: The level of mite populations and the time they occur will be controlled on bearing apple trees. The yield and quality of fruit will then be examined. Standard mite counting

techniques will be used to evaluate the effects of pesticide programs and cultural practices on mite populations, and insect populations and the damage they cause will be evaluated by various methods. The dynamics of mite populations will be examined under controlled conditions in bioclimatic chambers.

PROGRESS: Studies conducted during 1969 indicated that Zolone, Abar, or Torak could be used for codling moth control in integrated control programs without destroying predator mite (Metaseiulus occidentalis) populations whereas Gardona could not. Several candidate acaricides were eliminated from further consideration because of excessive predator kill. Additional studies on the aerial application of Guthion showed that a high rate was compatible with integrated mite control. Studies on timing of insecticide application for thrips control were begun. Good control of thrips was obtained with petal fall applications but damage had already occurred. Pre-pink applications did not control thrips.

SUPPORTED BY Washington State Government - Olympia

4.0897, CAUSES AND PREVENTION OF BEE POISONING BY CHEMICALS IN WASHINGTON

C.A. JOHANSEN, Washington State University, Agricultural Experiment Sta., *Pullman, Washington* 99163 (WNP01419)

OBJECTIVE: Determine which agricultural chemicals are responsible for bee poisoning and develop methods for preventing such losses.

APPROACH: Field tests of new insecticides to determine their relative hazard to bees. Comparative susceptibility of Megachile rotundata and the honey bee to insecticides. Cooperative development of safe bee forage areas isolated from cultivation. Field tests of bee poisoning vs. clover seed weevil control on white Dutch clover seed crops. Investigation of sprinkler irrigation application of insecticides to reduce bee poisoning hazard. Investigation of potential hazard involved in contamination of nectar and honey from plant systemic insecticide treatments.

PROGRESS: Mixtures of 2-3 insecticides and a new 6 lb/gal Systox formulation were more hazardous to alfalfa leafcutter bees and honey bees. Leafcutters several weeks old were more susceptible than newly- emerged individuals. Superior oil did not 'safen' Parathion sprays on alfalfa to honey bees. EL-273, Dikar, Galecron D, and Torak are relatively low in hazard to bees; while U 27,415, SD 17250, C-9491, AC 17413, and BAY 93820 are moderately to very highly hazardous. None of a series of 9 soil sterilants and fungicides proved hazardous to the alkali bee. Immature larval mortality of leafcutter bees was not significantly affected by Dylox or Dibrom sprays. Cygon gave the best results of 6 materials tested against lygus bugs and aphids in pre-bloom sprays. Biothion and Zolone show promise as bloom treatments against lygus bugs. Sorba-Spray Mg lowered pH of spray waters and increased the effectiveness of Dylox against lygus bugs. Vapona fumes were retained by a variety of materials and continued to cause killing of leafcutters. Chilling requirement for efficient emergence of diapausing leafcutter larvae is 4-5 months. Cold storage will kill emergent progeny of the leafcutter bee. There was little evidence of significant differences in female leafcutter production in nest tunnel depths from 2 to 4 inches. Locality, nest material, and seed vs. non-seed area variously affected leaf cutter larval mortality. Predators and parasites of the leafcutter destroyed 7.5% of the bee progeny.

SUPPORTED BY Washington State Government - Olympia

4.0898, CORN EARWORM CONTROL

E.C. KLOSTERMEYER, Washington State University, Agricultural Experiment Sta., *Pullman, Washington* 99163 (WNP01683)

OBJECTIVE: Develop an insecticide control program or other control for corn earworms on sweet corn compatible with beekeeping operations in Washington.

APPROACH: New insecticides will be evaluated on replicated plots of sweet corn and examination will be made on the degree of injury to the ears resulting from each treatment. Carbaryl will be used as a standard. Those insecticides showing promise will be further evaluated on larger plots by aircraft. These materials will also be evaluated in respect to honey bee mortality. Samples of corn and forage will be taken for residue determination. Biological observations will also be undertaken, including lights for evaluating adult populations, surveys of overwintering pupae and possibly the use of biological control agents.

PROGRESS: Low winter survival of pupae resulted in low early summer moth populations, but populations increased so that the late sweet corn in August and September had 75 to 100 per cent infested ears. Aerial applications of methomyl (Lannate) resulted in an average of 28 per cent infested ears compared with 52 per cent for Galecron and 100 per cent in untreated plots. Neither insecticide appeared hazardous to honeybees. Four applications with a high clearance sprayer produced 7 per cent infested ears with methomyl, 33 per cent with Bay 93820, 45 per cent with Galecron, 56 per cent with C9491, 78 per cent with Torak, and 75 per cent in untreated plots. Methomyl (Lannate) appears to be a very promising replacement for carbaryl for corn earworm control.

SUPPORTED BY U.S. Dept. of Agriculture

4.0899, WEED CONTROL IN CROP LANDS OF WESTERN WASHINGTON

D.V. PEABODY, Washington State University, Agricultural Experiment Sta., *Pullman, Washington* 99163 (WNP01123)

OBJECTIVE: Develop selective weed control methods in those horticultural and agronomic crops in which production is limited by weed competition. Determine the effect of new herbicides on those weed species which most seriously limit crop production as well as on the growth, vigor and yield of the crop itself. Integrate and alter standard crop production methods with regard to chemical weed control techniques so that the costs, effort, and time invested in producing the crop are decreased. Determine the persistence of herbicidal residues on crop plants as these may affect the use of such crops for animal and human consumption.

APPROACH: Testing of selective chemical weed control methods and materials which take advantage of growth and managerial differences between crops and weeds will be continued in the following crops: green peas, spinach, beets for seed, strawberries, blueberries, ornamental bulbs, Christmas trees and forages.

PROGRESS: Igran, terbacil, Tandex and an analog of Tandex (NIA 16476) are effective and selective in green peas. NIA 16476 also proved highly effective and safe in Christmas tree plantation as well as in tulips. In sweet corn, alachlor combined with atrazine eliminated both grassy and broad-leaved weeds. Post-emergence application of bromoxynil did not injure seedling alfalfa although other forage legumes demonstrated only low tolerance to this herbicide. No truly selective herbicide was found in cucumbers, however, the use of an activated charcoal spray applied in a narrow band over the row just prior to herbicide treatment may make it possible to use very active and effective herbicides in this sensitive crop. Field tests utilizing herbicide combinations (paraquat plus atrazine) with an especially designed planter demonstrated the feasibility of non-tillage farming in several different locations and soils. Non-tillage techniques also show promise in establishing new Christmas tree plantations. Cottonwood grown under conditions of high fertility, absence of competing vegetation and close spacing, have produced dry matter yields equivalent to three cords per acre in two years. Such yields compare favorably to cottonwood grown under more conventional conditions over a much longer period of time.

SUPPORTED BY Washington State Government - Olympia

4.0900, ORGANIC MERCURY POISONING IN SWINE

R.C. PIPER, Washington State University, Agricultural Experiment Sta., *Pullman, Washington* 99163 (WNP01606)

OBJECTIVE: Characterize and correlate the toxicity, signs, lesions, histochemical demonstration and localization of mercury and organ concentrations of mercury in acute and subacute experimental organic mercury poisoning of swine; study the pathogenesis of subacute organic mercury poisoning in swine; develop differential diagnostic techniques.

APPROACH: Swine will be given organic mercurial orally. The acute initial range finding trial will be at dosages of 0.2 to 0.3 log intervals per group. Signs, clinical laboratory results, gross

and microscopic lesions, histochemical demonstration and localization of mercury and organ concentrations of mercury will be determined and correlated. The pathogenesis of subacute organic mercury poisoning will consist of swine given a constant daily oral dosage of organic mercury and euthanatized at predetermined intervals to study the progression.

PROGRESS. To establish the diagnosis of mercury poisoning a sensitive histochemical technique for Hg that gives good cellular localization would be of value. A modified sulfide silver stain for metals was employed on tissues fixed in hydrogen sulfide-saturated 70% alcohol, 70% alcohol and 10% formalin. Rats were given HgCl(2) subcutaneously in dosages ranging from 50.0 to 0.025 mg Hg/kg body weight and renal and hepatic light microscopic lesions, Hg histochemistry and quantitative Hg organ analyses were compared. Hg was demonstrated in renal tissue sections of all rats in direct proportion to dosage, quantitative organ analysis and lesions. Correlation between microscopic lesions and specific Hg localization and concentration was excellent. Hg was demonstrated and localized at dosage levels (0.025 mg/kg b.w.) much lower than those causing signs of illness and producing microscopic lesions. Hg was detectable at tissue levels below the sensitivity (1.0 ppm) of the quantitative dithizone chemical procedure used. Moderate amounts of Hg were demonstrated consistently in livers to 4.2 ppm. (3.2 mg Hg/kg b.w.) and traces to 1.0 ppm. (0.2 mg Hg/kg b.w.). The ability to use formalin as the tissue fixative rather than H(2)S-saturated alcohol with equal sensitivity and less nonspecific staining is of value.

SUPPORTED BY Washington State Government - Olympia

4.0901, EFFECT OF ENVIRONMENTAL POLLUTION ON FISH DISEASES - ORGANOCHLORINE PESTICIDES AND DISEASE RESISTANCE MECHANISMS OF RAINBOW TROUT

G. WEDEMEYER, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Seattle, Washington* 98115

Inhibition of Na ion, K ion-activated adenosinetriphosphatase (salt pump) of kidney, brain and gills is potentially important in the susceptibility to stress, and hence infection, which has been noted in fishes chronically exposed to organochlorine pesticides.

The hypothesis will be investigated using chlordane, DDT, and endosulfan with the rainbow trout as the test species.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish

4.0902, SUBLETHAL AMOUNTS OF ORGANIC INSECTICIDES AND FISH

M. KATZ, Univ. of Washington, School of Fisheries, *Seattle, Washington* 98105

Because of the rapid progress of knowledge accumulated during the past year, the study is being modified significantly from the original application. There will be two major portions of the study.

1. The principal investigator and assistants plan to measure and identify the chlorinated hydrocarbons being accumulated by trout in the commercial, state and federal trout hatcheries in Eastern Washington. After these parameters are established, the egg-bearing females will be transported to a commercial hatchery in the vicinity of Seattle, and the loss of chlorinated hydrocarbons will be followed in the adult fish and the eggs that are derived from these fish.

This is an effort to determine the rate of excretion or breakdown of chlorinated hydrocarbons that is occurring under actual hatchery operating conditions. These data obtained will document the solution to an insecticide toxicity problem that has been solved empirically by the commercial trout grower. The state and federal hatcheries who have not been able to follow this procedure are suffering disastrous egg losses. The loss of the chlorinated hydrocarbons will be evaluated by chemical analysis of the tissues of the adult fish and of the developing eggs.

2. A second project is to investigate the possible use of activated charcoal in fish feeds to reduce the absorption of chlorinated hydrocarbons which are almost universally present in the prepared fish foods fed to trout. Artificial diets will be made up containing 0.1, 1.0 and 5.0 ppm of DDT and other diets will be made up of the same concentrations of DDT but containing 0.1 percent, 1 percent and 5 percent activated charcoal. These diets will be fed to fish and their growth mortality and reproductive success will be measured. If preliminary trials are successful, appropriate analyses for DDT will be made.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

4.0903, THIN LAYER CHROMATOGRAPHIC IDENTIFICATION OF MS-222 IN FISH MUSCLE TISSUE, BLOOD, BRAIN TISSUE, AND IN WATER (ABBREV)

J.L. ALLEN, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *La Crosse, Wisconsin*

Determination of MS-222 residues by the modified Bratton-Marshall method of Walker and Schoettger gives good quantitative results. However, this method does not identify MS-222 or distinguish it from other naturally occurring aromatic amines present in fish. Before clearance of the drug by the U.S. Food and Drug Administration can be obtained, a second, confirmatory method for MS-222 is required.

Thin layer chromatography could provide a fast, semi-quantitative identification of MS-222 residues. This method would identify MS-222 residues in fish blood, and in such tissues as fish muscle and brain. Thin layer chromatography can thus be used in conjunction with Bratton- Marshall method to provide a quantitative, positive identification of MS-222 residues.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0904, INVESTIGATIONS ON FATE OF CONTROL AGENTS IN FISH. WORK UNIT RESIDUES OF MS-222 IN NORTHERN PIKE, MUSKELLUNGE, WALLEYE. (ABBREV)

J.L. ALLEN, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *La Crosse, Wisconsin*

MS-222 (methanesulfonate of ethyl m-aminobenzoate) is widely used as an anesthetic for northern pike, muskellunge and walleye. It has has not been cleared for use on these species, however, by the U.S. Food and Drug Administration. The requirements for clearance includes information on residues of the drug in the tissue of these fish.

The Bratton-Marshall method was effectively modified for detection and measurement of MS-222 in fish tissue (work Unit FR-2170-742-65-2). The residues of free and acetylated MS-222 are determined in the muscle tissue of northern pike, muskellunge and walleye which have been anesthetized to a stage of medullary collapse and recovered in fresh water. Positive identification of the MS-222 residues are obtained by confirmatory analyses using thin layer chromatography.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0905, RESIDUES OF FISH CONTROL AGENTS - FLUOROMETRY, THIN LAYER AND GAS CHROMATOGRAPHY FOR ANALYSIS OF QUINALDINE RESIDUES IN FISH (ABBREV)

J.L. ALLEN, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *La Crosse, Wisconsin*

Quinaldine is widely used as a fish anesthetic. It has not been cleared for this use, however, by the U. S. Food and Drug Administration. The requirements for clearance include a need for information on the residues of quinaldine in fish tissues.

Fluorometry, thin layer chromatography, and gas chromatography all appear capable of detection and measurement of quinaldine. A combination of two of these methods would provide quantitative measurement of quinaldine residues as well as identification of the residues. Procedures for extracting quinaldine from treated fish and cleaning up these extracts must be developed. Bass, catfish, and bluegill are exposed to various concentrations of the chemical and attempts are made to extract, clean up the extracts, and detect it or its metabolites in fish tissues.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0906, THE EFFECTIVENESS OF MCN-JR-7464 AS AN ANESTHETIC FOR SELECTED SPECIES OF FISH (ABBREV)
R.A. SCHOETTGER, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *La Crosse, Wisconsin*

Anesthetics are used widely in the culture and management of sport and commercial species. Laboratory tests of potential anesthetics are needed to define effective and safe concentrations which may be employed to facilitate the handling or transport of fish.

The chemical is tested on selected species such as rainbow trout, brown trout, brook trout, lake trout, channel catfish, bluegill, and largemouth bass. Concentrations and exposure times for desired depths of anesthesia are determined. Recovery time is recorded for brief and extended periods of anesthesia. The tests are conducted at 7,12,17,22 and 27 degrees C. The influences of pH, water hardness, size of fish, and repeated anesthetization on the efficacy of McN-JR-7464 are measured. Anesthetized fish are recovered in fresh water and held for several weeks to observe post-treatment mortality, general condition and appetite. They are also given periodic hematological examinations. The toxicity of the compound to reproductive products of fish is determined.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish

4.0907, THE EFFECTS OF ANTIMYCIN A ON THE METABOLISM OF SELECTED TISSUES IN FISH (ABBREV)
G.E. SVENDSEN, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *La Crosse, Wisconsin*

The literature indicates that antimycin A is a strong inhibitor of electron transport in the oxidative phosphorylation system. The tissues or organs of fish which are affected by the chemical, however, have not been distinguished. Laboratory tests are needed to determine whether the effects of antimycin are general or specific to certain tissues and whether they differ according to species susceptibility or method of treatment.

Resistant and susceptible species such as bullhead and rainbow trout respectively are treated with antimycin A by IP injection or by exposing them to solutions of the toxicant. After various periods of exposure, treated and control fish are killed and various tissues, for example, gill, brain, liver, kidney and muscle are dissected. The metabolic rates of tissues, measured manometrically, are used to evaluate the effects of antimycin. The results are compared with in vitro effects of antimycin on tissue metabolism.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0908, WILDLIFE PATHOLOGY RESEARCH
J.B. HALE, State Dept. of Nat. Resources, *Madison, Wisconsin* 53701

Objective: Determine the presence, prevalence, etiology, natural history and importance of infectious diseases and other pathological conditions which occur in Wisconsin wildlife and their relationship to various environmental contaminants.

Procedures: Gather wildlife morbidity and mortality data through a statewide necropsy service; determine the prevalence and epizootiology of specific infectious diseases in Wisconsin wildlife; determine the effects of stress on hosts with sublethal levels of pesticides.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0909, TRACE LEVELS OF PESTICIDE RESIDUES IN AGRICULTURAL COMMODITIES IN MARKETING CHANNELS
R.L. BRADLEY, Univ. of Wisconsin, Agricultural Experiment Sta., *Madison, Wisconsin* (WIS01301)

OBJECTIVE: Develop packaging techniques for reducing or preventing pest damage in agricultural commodities. Study effects of pesticides on acceptability and/or nutritive value of agricultural commodities. Develop procedures for the removal, reduction or de-toxification of pesticides and conversion products in agricultural commodities.

APPROACH: Permeability of several food packaging materials to pest organisms and the growth rates of the organisms in foods packaged in various materials will be investigated. By applying results of permeability and growth rate studies packaging techniques will be used to prevent or greatly reduce pest damage in packaged foods. The influence of preparation and processing techniques on the stability of various pesticides will be studied. Processing methods to be studied will include canning, freezing, freeze drying and others.

PROGRESS: Excellent progress has been made during the past year. Groups of baby chicks fed a synthetic and natural diet containing different levels of malathion showed no anemias from an iron deficiency. Concentrations above 1,000 mg malathion/kg feed produced growth retardation; however, concentrations of malathion less than 100 mg/kg feed showed some stimulation of growth. Moreover, if the diet of these groups of chicks is alternated daily from natural feed to a contaminated feed containing as much as 5,000 mg malathion/kg, a definite stimulation of growth occurs. This may be due in part to the fact that the birds appear to reject the contaminated feed and then consume more than the normal amount of noncontaminated feed the following day. Growth retardation in these chicks may be attributed to two factors: the toxic effect of the malathion, and the rejection of feed containing these high amounts of organophosphate pesticide.

SUPPORTED BY U.S. Dept. of Agriculture

4.0910, THE EFFECT OF PROCESSING ON THE PESTICIDE CONTENT OF DAIRY PRODUCTS
R.L. BRADLEY, Univ. of Wisconsin, Agricultural Experiment Sta., *Madison, Wisconsin* (WIS01307)

OBJECTIVE: Determine what processing steps alter effect of concentrations of pesticides in milk and milk products. Determine the effect on lactic fermentations and potential growth of pathogens in Cheddar cheese made from milk contaminated with chlorinated pesticides. Determine what bacterial metabolic functions are affected by chlorinated pesticides.

APPROACH: Cheddar cheese will be manufactured using mixed and single strain starters, accepted commercial practices, and milk contaminated with trace quantities of chlorinated pesticides. Acidity, pH, and bacterial analysis will be made during manufacture and storage to determine the extent and duration of retardation of acid development and the particular organisms affected. The possibility of overgrowth by Staphylococcus aureus and other undesirable contaminants will be determined after direct inoculation of the cheese during manufacture. Populations of these undesirable organisms will be enumerated at specific intervals during storage using standard methodology. Model systems will be developed to study the mechanism by which chlorinated hydrocarbons retard acid development. Michaelis constants will be derived to determine the type of enzymatic inhibition exerted. Based on these data, processing procedures will be designed to negate the effect of trace quantities of chlorinated pesticides during manufacture of cheese.

PROGRESS: Several single strains of Strept. cremoris, Strept. lactis and a mixed strain lactic culture used to determine effect of organochlorine pesticides on fermentation of lactose to lactic acid. These were evaluated in naturally and artificially contaminated milks. Chlordane and thiodan used at concentrations of 0.01, 0.1, 0.5, 1.0, 10, 50 and 100 ppm/g fat and added in ethanol. Milks naturally contaminated with chlordane, thiodan, dicofol also evaluated. In pilot cheese-making trials, milk naturally contaminated with chlordane required a time factor of 2X to reach pH 4.5 when compared with noncontaminated milks. Milk artificially contaminated to contain 1 ppm chlordane (per gram of fat) showed little difference in acid production. 10 cultures of lactose fermenters exhibited some sensitivity to milks artificially contaminated to contain 1 ppm thiodan, while natural contamination at 0.04 ppm showed no effect. Slight inhibition observed with as little as 0.125% ethanol in control milk.

SUPPORTED BY U.S. Dept. of Agriculture

4.0911, TRUCK CROP AND POTATO INSECTS AND THEIR CONTROL
R.K. CHAPMAN, Univ. of Wisconsin, Agricultural Experiment Sta., *Madison, Wisconsin* (WIS00418)

4. PESTICIDES

OBJECTIVE: Study the economic pests of vegetable crops in Wisconsin and devise effective, economic and feasible control measures.

APPROACH: Determination of life cycles and habits of the pest species as they relate to susceptibility to various control techniques including chemical, biological, and plant resistance methods. Emphasis is being given to the use of systemic insecticides for foliage feeding species and to particular formulations and very specific placement of insecticides for soil pests.

PROGRESS: New and different types of insecticides must be constantly screened for their effectiveness in vegetable insect control because of the development of resistance by the insects to recommended materials and the deletions for their use by federal authorities while at the same time the public demands food that is absolutely free from insect damage, frass or parts and hazardous chemical residues. For the control of imported cabbageworms and cabbage loopers which have become resistant to such chemicals as DDT, parathion, endrin and mevinphos, Monitor showed outstanding characteristics. Excellent general insect control was obtained on potatoes and beans by foliar applications of Azodrin, Monitor, Lannate, Furadan, and VSC506. Systemic materials which gave good insect control on potatoes for the whole season in addition to the presently used phorate and disulfoton included Furadan, Temik and Dasanit when they were applied in the soil at planting time. No satisfactory materials are available for recommendation for control of the cabbage maggot on cruciferous crops in Wisconsin. Unlabelled materials which gave good control when used as granules in a narrow band in or near the seed furrow include: Dasanit, Furadan, Dursban, Baygon, Bay 37289 and compound 4072. By regulating the placement of the insecticides phytotoxicity can be reduced and better use made of the natural predators of the maggot.

SUPPORTED BY Wisconsin State Government - Madison

4.0912, INSECTICIDES AND REPRODUCTION OF COTURNIX QUAIL

F.L. CHERMS, Univ. of Wisconsin, Agricultural Experiment Sta., *Madison, Wisconsin* (WIS01298)

OBJECTIVE: Determine if low levels of commonly used insecticides, such as malathion, affect fertility, and hatchability when used as feed additives. Determine effect of compounds on spermatogenesis of male testes. Determine if compounds disrupt nuclear material of germinal disk, i.e. are mutagenic.

APPROACH: Coturnix quail, a rapid growing, early maturing bird with excellent reproductive efficiency is an ideal animal to study effects of insecticides on reproduction. Information obtained with this animal might apply to both domestic and wild birds. Preliminary studies involve feeding of compounds under test to determine general effect on reproduction. In instances where detrimental effect is found, further tests will be conducted to ascertain site of action of compound, i.e. either male testes or germinal disk.

PROGRESS: Four generations of selection for resistance to 200 ppm DDT have been completed in the artificial and natural selection populations. Up to this point, there is no difference in the length of time needed to reach 50% mortality in the selected populations as compared to a non-selected control. No differences exist between any group for fertility and hatchability. One apparent difference lies in body weight at 30 days of age where both selected populations are heavier than the control. In a separate experiment, survivors of DDT feeding to 30 days were maintained on three levels (0, 50, and 200 ppm) through a 6 weeks laying period to determine effects on shell thickness. Regardless of the bird source (artificial, natural, or control populations) there were no differences in shell thickness on any treatment.

SUPPORTED BY U.S. Dept. of Agriculture

4.0913, INSECTICIDES AND EGG-SHELL DEPOSITION

J.J. HICKEY, Univ. of Wisconsin, Agricultural Experiment Sta., *Madison, Wisconsin* (WIS01249)

OBJECTIVE: Evaluate the wildlife side-effects of insecticidal use and to work out the kinetics of DDT transfer through different ecosystems.

APPROACH: The avian effects of DDT in Dutch elm disease control have been evaluated on 7 Wisconsin study areas and the transfer of DDT through soils, earthworms and birds is now being measured. A second project is measuring residues in Lake Michigan sediments, fish, and gulls. A third is evaluating the current status of the peregrine falcon in eastern U.S.

PROGRESS:

SUPPORTED BY Wisconsin State Government - Madison

4.0914, BIOLOGICAL FACTORS IN THE MANAGEMENT OF LAKE FLIES

W.L. HILSENHOFF, Univ. of Wisconsin, Agricultural Experiment Sta., *Madison, Wisconsin* (WIS01039)

OBJECTIVE: The ecology of the bottom fauna of Lake Winnebago and 14 other Wisconsin lakes, and the chemical and physical properties of these lakes are being studied to determine the factors that are responsible for nuisance population of midges. The biology of the Lake Fly, Tendipes plumosus, in Lake Winnebago is being intensively studied in the field and in the laboratory. The parasites and predators of T. plumosus are being investigated to determine their potential for biological control. Lakes treated by the Wisconsin Conservation Department with toxicants to remove undesirable fish populations are being studied to determine the effects of the toxicants on the bottom fauna and the effect of fish predation of this fauna.

SUPPORTED BY Wisconsin State Government - Madison

4.0915, ACTION MECHANISMS OF INSECTICIDAL DERIVATIVES

F. MATSUMURA, Univ. of Wisconsin, Agricultural Experiment Sta., *Madison, Wisconsin* (WIS00822)

Objective: Explore the possibilities of using insect pathogens or analyses ther naturally occurring compounds as insecticides. Study the mechanisms of action of various chlorinated insecticides on the nervous systems of animals. Investigate the fates of chlorinated hydrocarbon insecticides in the environment with particular emphasis on the microbial degradation of various pesticides.

Approach: The non insecticidal materials proposed for investigation are hormones, insect pheromones, chemosterilants and other naturally occurring insecticidal analogs. The major approach here is to conduct laboratory evaluation of new materials. In some cases attempts will be made to identify the toxic or active principles involved. Study the mode of action of insecticidal analogs, efforts will be made first to investigate the direct effects of biochemical means. Also efforts will be made to study the degradation enzymes which metabolize insecticidal substrates in various animals.

Progress: A number of microorganism colonies were found to be capable of degrading chlorinated hydrocarbon insecticides. About 12 colonies were particularly active degrading dieldrin. A number of hitherto unknown metabolites were chemically identified from the degradation products of dieldrin by those microorganisms. The mechanism of action of DDT was studied in the brain and the liver of the rat. DDT was found to preferentially bind in the synaptic junctions. DDT was also found to influence the function of ion transport by the liver tissue resulting in drastic alteration of the levels of other insecticides' storage. Efforts were made to study the enzymes which hydrolyze various insecticidal organophosphates and carbamates. Each insecticide tested was found to be simultaneously hydrolyzed by a number of esterases. The nature of these esterases was studied. Efforts were also made to study naturally occurring insecticides. As a result of an extensive screening, a number of fungal products were found to possess potent insecticidal properties against mosquito larvae. The trail-following pheromone of a southern subterranean termite was chemically identified. It is cis-3, cis-6, trans-8-dodecatrien-1-ol.

SUPPORTED BY U.S. Dept. of Agriculture

4.0916, MECHANISMS OF INSECTICIDE DEGRADATION

F. MATSUMURA, Univ. of Wisconsin, School of Agriculture, *Madison, Wisconsin*

Attempts will be made to survey the patterns of enzymes degrading hazardous insecticides in insects and mammals including men. The enzymes available for insecticide degradation will be partially purified and interspecific differences will be studied. Whenever the mode of action of a particular insecticide is not known, efforts will be made to elucidate the site of insecticidal attack as well as the mode of poisoning. The resulting data will be analysed so as to estimate the actual hazard level of these insecticides in men and other animals. Several naturally occurring compounds which show specific toxicity towards a certain group of insects but not to mammals or other unique biological activities that can be utilized to control insect pests will be studied in the hope of finding the clue for their selective toxicity, as well as new approaches to efficient control measures for various insect pest species.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.P.P.

4.0917, CAUSES OF ABORTIONS IN DAIRY CATTLE WITH PARTICULAR REFERENCE TO PESTICIDES AND MOLD TOXINS

W.E. RIBELIN, Univ. of Wisconsin, Agricultural Experiment Sta., *Madison, Wisconsin* (WIS05016-6016)

OBJECTIVE: Determine the causes of dairy cattle abortion in Wisconsin, both microbial and not, and the relative frequency of all.

APPROACH: Aborted fetuses and placentas will be examined as submitted to State Animal Health Laboratory. Studies will include gross and microscopic pathology, bacterial culture, virus isolation, pesticide determinations. Dams will be assessed for uterine bacteria, serum electrolytes, methemoglobin, antibodies. Feed will be tested for mycotoxins by feeding to pregnant rats. Herd history will be recorded. All cases will be tabulated and incidences determined. New chemical or microbial agents encountered will be given to pregnant cattle to verify abortigenic properties.

PROGRESS: 37 farms with cattle abortions studied. As usual, most could not be diagnosed by usual diagnostic means. Following new causes were detected: Streptococcal infection of fetus, Lymphatic leukemia fetus within normal mother, Aspergillus veinti toxins from moldy feed. Isolation, culture, and feeding of known estrogen-producing mold, Gibberella zeae, did not produce abortion in pregnant cow. No fetal tissues contained pesticides. No farms where market milk had been held because of pesticide contamination had abortions. Feeding of 5 pesticides to 9 pregnant cows did not produce abortion.

SUPPORTED BY U.S. Dept. of Agriculture

4.0918, EFFECT OF EXERCISE WITH HIGH CARBOHYDRATE OR HIGH FAT DIETS CONTAINING DDT

P.H. DERSE, Warf Institute Incorporated, *Madison, Wisconsin* 53706 (HN07-06-01-C)

OBJECTIVE: Biochemical and physiological response of rats to high carbohydrate or high fat diets containing low levels of DDT when sedentary or forced to exercise vigorously.

APPROACH: Feed rats from weaning until 200 days of age nutritionally adequate diets containing high levels of fat or carbohydrate. High fat diet will contain a high content of unsaturated fats. Carbohydrate diet will contain 1:1 mixture of sucrose and cornstarch. A standard casein diet will serve as control. Feed each diet with and without a low level of DDT. At 100 days divide rats on each diet into two groups, one to be kept relatively sedentary and one to be forced to exercise vigorously. Maintain weights and food intake records. Sacrifice rats at 200 days of age. Determine DDT content of brain, liver and adipose tissue. Examine selected tissues histologically. Measure fat, cholesterol, protein, DNA and RNA content of livers; determine proximate analysis of carcass and cholesterol level in blood.

PROGRESS: Laboratory work is continuing on a project which will provide information on the physiological responses of rats forced to exercise and fed diets either high in fat or carbohydrate. The feeding study is now complete but the results from the laboratory analyses are not yet available.

SUPPORTED BY U.S. Dept. of Agriculture

4.0919, CHRONIC TOXICITY OF INSECTICIDES TO COLD-WATER FISH

D.V. SWEDBURG, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Jackson, Wyoming*

This work is a continuing program for deriving toxicities of various pesticides and combinations of pesticides to cold-water fishes. Static testing conditions yield median tolerance limits (TLm) for 24-96 hour exposures and continuous-flow conditions are used for exposures as long as 30 days. The tests include standard and varied conditions of temperature and water quality. Biological effects other than mortality are evaluated when appropriate.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0920, CHRONIC TOXICITY OF PESTICIDES TO COLD-WATER FISH

D.V. SWEDBURG, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Jackson, Wyoming*

Aroclor 1248 will be administered for 160 days to immature lake trout in dietary concentrations of 1,2, 3,6, and 12.0 mg/kg of food giving dosage rates of 36.9, 108, and 360 ug/kg of body weight per day. Aroclor residues, mortality, and pathology will be evaluated throughout treatment and for 70 days after treatment. The fish will be tested for thyroid activity, recovery time from hexabarbital anesthesia, and their ability to withstand thermal shock after the exposure.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0921, INFLUENCE OF PESTICIDAL CHLORINATED HYDROCARBONS ON ADAPTATION MECHANISM IN POULTRY

M. DELAK, Univ. of Zagreb, *Zagreb, Yugoslavia* (E30-AH-170329053701Y)

OBJECTIVE: Determine the effect of chlorinated hydrocarbons on the adaptation mechanism in poultry.

APPPOACH: The intensity of reaction of the adrenal cortex to various chlorinated hydrocarbons will be determined. The amount of residue in tissue of treated animals will also be studied. Later the reaction of the adaptation mechanism to specific amounts of pesticide, to various duration of application will be determined. Also different chlorinated hydrocarbons and combinations of them will be studied.

PROGRESS: Comparative investigations of the effects of technical grade DDT and the p,p'-DDT and o,p'-DDD isomers indicated that 30 day administrations of 100 ppm in the feed of chickens of the DDT technical and o,p'-DDD inhibited, but did not completely block, corticosterone synthesis. The rate of degradation of the hormone in the blood was also increased up to 20 days of treatment. With higher oral doses (300 & 500 ppm) of technical grade DDT and p,p'-DDT, mild depression and appetite loss was observed and adrenal function, was intensified, but o,p'-DDD continued to depress adrenal function. It is suggested that most of the adrenocorticolytic activity of technical grade DDT is due to the o,p'- DDT isomer which makes up approximately 24% of the technical product.

SUPPORTED BY U.S. Dept. of Agriculture

E. ADVERSE EFFECTS ON THE GENERAL ENVIRONMENT

Nonspecific Studies on the Animal and Plant Community and Habitat. General Ecological Effects, Material Effects.

4.0922, CHEMISTRY AND TOXICOLOGY OF INSECTICIDES

R.S. BERGER, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA00192)

OBJECTIVE: Determine major chemical changes organic insecticides undergo in plants, insects, and other animals, and evaluate the role these changes play in the activation, detoxication,

selective toxicity, accumulation of residues, and resistance of insects to insecticides. Determine specific biochemical and physiological effects of different classes of insecticides and determine how these effects are influenced by the nutrition, environment, and physiological condition of the test animals.

APPROACH: Radioactive insecticide will be used, products isolated by solvent partition and chromatographic procedures and identified. Isolated enzyme systems studied and significance in activation, detoxication, selective toxicity, residues, and insecticide resistance evaluated. Influence of diet, environment, and condition of test animal on response to insecticide will be studied.

PROGRESS: Fourteen-, 16-, and 18-carbon fatty acids were increased in the body fat of Heliothis zea larvae by furnishing them in the diet at concentrations of 0.3 to 1.0 per cent. Fatty acids not synthesized by the insect, particularly the essential linolenic and linoleic acids, were increased to a greater extent than those which can be synthesized from non-fat sources. There was no apparent interconversion between different fatty acids of the same chain length in larvae when one was furnished in the diet. When larvae contained a high level of a poly- unsaturated fatty acid, the amount of the mono-unsaturated acids, especially palmitoleic, was decreased. Larvae of different fatty acid compositions as a result of rearing on fat-fortified artificial diets were treated topically with methyl parathion, endrin, and carbaryl for determination of LD-50 dosages. There were no large differences in susceptibility to these toxicants which could be attributed to the nature of fatty acids in the insect.

SUPPORTED BY U.S. Dept. of Agriculture

4.0923, ORGANIC RESIDUES AND SOIL MICROORGANISMS

E.A. CURL, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA00237)

OBJECTIVE: Behavior of soil-borne pathogens as influenced by soil microorganisms, living plants, plant residues and soil amendments and develop techniques for studying soil microbial communities.

APPROACH: Principal pathogenic fungi to be used are Sclerotium rolfsii, Rhizoctonia solani, Fomes annosus, Fusarium oxysporum f. vasinfectum, Pythium ultimum, and Helminthosporium spp. Procedures will be designed to: determine direct and indirect effects of chopped plant residues and organic herbicides on growth, reproduction, and survival of specific fungi in controlled environments; influence of these materials on antagonistic microflora of soil and on the lytic and fungistatic effects of soils on spores, sclerotia and mycelia; role of C/N ratios in biological control phenomena; effects of residual factors of field-cropped soil on pathogenic fungi; influence of root rhizosphere, rhizoplant, and exudates on germination of spores and sclerotia; and develop and improve techniques for studying ecology of soil microorganisms.

PROGRESS: Research continued on: ecology of long-term fertility plots with regard to influence on fungal pathogens; influence of herbicides on sclerotium production; and enzymatic interaction of fungi in soil culture. Soil from plots of various fertility treatments continued to have little effect on sclerotium germination by Sclerotium rolfsii but affected subsequent sclerotium production. Germination of chlamydospores of Fusarium vasinfectum was lowest in Plot C (no fertilizer) and Plot 8 (PKN, no lime). Percentage of natural organic particles in assay plates varied considerably among plots and was attributed primarily to Trichoderma and 2-3 bacteria colonizing the particles. Rhizoctonia infestation corresponded to plot fertility. Production by Sclerotinia trifoliorum also was significantly affected; dry weights produced in soil treated with diuron, EPTC, and cotoran were reduced. Interaction studies with S. rolfsii and Trichoderma viride in soil showed that maximal proteolytic action of the latter coincided with increase in soil pH from 5.2 to 6.3 and above.

SUPPORTED BY U.S. Dept. of Agriculture

4.0924, RESIDUES OF SELECTED PESTICIDES

G.W. WARE, Univ. of Arizona, Agricultural Experiment Sta., *Tucson, Arizona* 85721 (ARZT-2020-4161-016)

OBJECTIVE: Routes of pesticide residue entry into marketable commodities. Determine routes of pesticide residue entry in forage, animals and animal products. Correlate forage residues with translocation from soil, dust contamination and absorption of volatile pesticide. Trace residues in animals and seek cultural methods for reducing forage residues.

APPROACH: Concentrate on Arizona's ever-present DDT-forage problem, through radiocarbon-DDT translocation and soil half-life studies under fallow and irrigated conditions. Vapor-phase or codistillation of DDT and other compounds in the field lab will receive prime attention since Arizona's arid, irrigated conditions combined with severe air inversions may offer unique opportunities for this phenomenon to occur. A search for cultural practices to reduce initial application drift and indirect contamination from volatiles, dust and translocation will follow.

PROGRESS: Based on data from work in this laboratory over the past 30 months, the Arizona Board of Pesticide Control placed a one-year moratorium on the agricultural use of DDT, with the recommendations from cotton, beef, dairy, feed and hay commodity groups. The use-history of DDT in Arizona agriculture has been: 1965 - 554,000 lbs; 1966 - 1,072,000 lbs; 1967 - 2,519,000 lbs; 1968 - 250,000 lbs; and 1969 none. With this several old economic and related problems have been solved, with the consequences of producing several new ones. An on-column extraction-cleanup for animal fat has been developed which reduces the amount of glassware and time involved by one-half. From the DDT moratorium monitoring of DDTR in agricultural commodities beef fat residues appear to have dropped from 1.0 ppm in November, 1968, to 0.68 ppm in May, 1969. Green alfalfa residues in 3 counties dropped in May to 23% of the levels found in January. Soil levels have not changed significantly during that period in alfalfa fields or desert soils.

SUPPORTED BY U.S. Dept. of Agriculture

4.0925, PESTICIDE RESIDUES ON ARIZONA CROPS

G.W. WARE, Univ. of Arizona, Agricultural Experiment Sta., *Tucson, Arizona* 85721 (ARZT-0206-4162-147)

OBJECTIVE: Investigate the deposition and metabolism of pesticides by animals, plants and microorganisms. Investigate the interrelations of crops, soil, air and water as they influence pesticide deposition.

APPROACH: Metabolism and deposition studies will involve normal and radio-labeled insecticides to be detected by liquid scintillation, thin layer and gas chromatography. These include all classes of insecticides, to be investigated in the lab, greenhouse and field. Crop residues will be determined and correlated with soil and water residues to isolate the contribution of each by quantitating pesticide additions to soils directly through application, irrigation and canal systems, and indirectly from field effluents into others, and the resulting crop residues from routes other than deliberate application.

PROGRESS: A laboratory method for the separation of DDT residues from interfering toxaphene components has been developed. It consists of reacting the Florisil eluate with saturated ethanolic-NaOH for 1 hour, followed by injection into a gas chromatographic column packed with 1 inch each of $CdCl(2)$ and $Na(2)CO(3)$ at the injection end. Generally, the DDT moratorium in Arizona, begun in January 1969, has been successful during its first year despite some apparent agricultural use of DDT in the three major irrigated areas. Alfalfa residues declined notably as did feedlot beef fat. Both irrigated and desert soil residues, however, remained relatively stable showing little decline.

SUPPORTED BY Arizona State Government

4.0926, FATE OF INSECTICIDE CHEMICALS IN RELATION TO NONPERSISTENCE AND SPECIES SPECIFICITY

J.E. CASIDA, Univ. of California, Agricultural Experiment Sta., *Berkeley, California* 94720 (WO2217)

OBJECTIVE: Provide information, including explanation of biological action of compounds, their chemistry, degradation, and reactions as modified by synergists, leading to the development of selective insecticides for forest insects.

APPROACH: In vitro tests with microsomes from rat liver and insects will be made to prepare biological degradation

products for separation, purification, and identification or characterization. In vivo tests to determine toxicity, enzymic effects, and biological effects of chemicals. Persistence and stability of a proposed insecticide will be determined by application to laboratory-reared plants and to inert surfaces, using light of various spectral characteristics, followed by residue determinations at intervals.

PROGRESS: A ketone analog of allenthrin was produced with enhanced insecticidal activity against a number of insect species, including Choristoneura fumeriferana. Studies with water-soluble metabolites from eight substituted phenyl methylcarbamate and two substituted pyrazolyl dimethylcarbamate insecticide chemicals injected into bean plants were completed. Research to synthesize 'pyrethroid-like' compounds lacking cyclopropane or ester groups led to development of a number of such compounds that respond to pyrethrum synergists and block nerve excitability in the same manner exhibited by allethrin.

SUPPORTED BY U.S. Dept. of Agriculture

4.0927, BIOLOGICAL ACTIVITY OF INSECTICIDAL DERIVATIVES

J.E. CASIDA, Univ. of California, Agricultural Experiment Sta., *Berkeley, California* 94720 (CA-B0-ENT-2222)

OBJECTIVE: Provide fundamental information on the toxicology of insecticides necessary for their safe and efficient utilization.

APPROACH: The metabolic fate of the compounds will be defined in the variety of organisms which they might contact under normal use conditions. The biological activity of metabolites will be determined in order that the contribution of these metabolites to the over-all toxicological picture and the residue hazards can be evaluated. Attention will be focused not only on the principal mode of action of the pesticide but on deleterious side effects. The biochemical lesion leading to poisoning will be investigated through biochemical and physiological techniques.

PROGRESS: Rotenone and other chromanochromanones markedly enhance the rate of photoalteration of cyclodiene insecticides, such as dieldrin, allowing some control in reducing or prolonging the life of toxic residues from these persistent insecticides on plants. Rotenone photo-decomposes to yield rotenolones, rotenonone, derritol, and tubaic acid. Certain insecticide synergists inhibit microsomal mixed function oxidases of mouse liver for long periods and so synergist-treated mice are very susceptible to poisoning by barbiturate drugs and insecticides that are detoxified by this enzyme system. The low toxicity of pyrethrins to mammals as compared with insects appears to result in part from more rapid oxidation, at multiple sites on the molecule, in mammalian species. Resistant housefly strains vary in the substrate specificity of their microsomal mixed function oxidases and in the spectral properties of their cytochrome P-450. Rats and mice metabolize dessin by ester hydrolysis, reduction of nitro groups, and oxidation of the sec-butyl side chain. Radiosynthesis procedures were developed for pyrethrins I and II and several related compounds. Feasibility probes are underway on use of radioautography to localize the site of action of pyrethroids in the insect nervous system. Studies were initiated on the possible role of enzymes in degradation of captan-type fungicides, methylation of organophosphate and carbamate insecticides, and cleavage of propynyl ether and ester synergists.

SUPPORTED BY California State Government - Sacramento

4.0928, EFFECT OF SOIL FUMIGANTS AND FUNGICIDES ON FRUIT AND VEGETABLE QUALITY

G. EMERSON, Univ. of California, Agricultural Experiment Sta., *Los Angeles, California* 90024 (HN3-33(C)A)

OBJECTIVE: Determine the effects of soil fumigants and fungicides used in the production of selected fruits and vegetables on their quality and composition.

APPROACH: A root crop, a legume, a leafy vegetable, and a small fruit will be grown in soil treated with a commercial fumigant. Fruits representing pre- and post-harvest use of fungicides will be treated with a fungicide recommended for the selected fruit. Foods will be analyzed for selected nutrients. Pesticide residues will be determined. Panel evaluations of flavor, color, and texture will be made on fresh and prepared foods.

PROGRESS: One additional crop year for carrots grown on Telone- treated soil and two crop years for carrots grown on dibromochloropropene and ethylenedibromide fumigated soils were gained in this reporting year. Two additional crop years were gained for lima beans grown on ethylenedibromide treated soil. The additional crop years substantiate the earlier findings that soil fumigation with dibromochloropropene, ethylenedibromide, and 1,3-dichloropropene can result in an increase in the beta-carotene content of carrots in the range of 20% to 40%. There were no differences in quality, specifically maturity, between treated and untreated samples as judged by sensory evaluation. The loss of equipment, space, and a notebook in the laboratory fire has proven to be a greater handicap than expected. At this stage the laboratory analyses are judged to be approximately three- fourths complete.

SUPPORTED BY U.S. Dept. of Agriculture

4.0929, EFFECT OF SOIL FUMIGANTS AND FUNGICIDES ON FRUIT AND VEGETABLE QUALITY

G. EMERSON, Univ. of California, Agricultural Experiment Sta., *Los Angeles, California* 90024 (HN3-33(C))

OBJECTIVE: Determine the effects of soil fumigants and fungicides used in the production of selected fruits and vegetables on their quality and composition.

APPROACH: A root crop, a legume, a leafy vegetable, and a small fruit will be grown in soil treated with a commercial fumigant. Fruits representing pre- and post-harvest use of fungicides will be treated with fungicide recommended for the selected fruit. Foods will be analyzed for selected nutrients. Pesticide residues will be determined. Panel evaluations of flavor, color, and texture will be made on fresh and prepared foods.

PROGRESS: The production and harvest of carrots, tomatoes, lettuce, lima beans, oranges, and strawberries in two crop years has been completed. The laboratory analyses are approximately half completed.

4.0930, BIOLOGICAL HAZARDS OF PHOTOTRANSFORMED PESTICIDES

M. TANABE, Stanford Research Institute, *Menlo Park, California* 94025

The increasing use of pesticides in our environment emphasizes the importance of knowing their fate after application. Light-induced transformations of these chemicals is an area that has received little study. Photolytic transformations of pesticides introduce unknown materials into the environment. These must be evaluated for their biological and chemical properties. We hope to elucidate the nature of these phototransformed products and study their effects in various biological systems. The physical, chemical, and biological properties of these new chemicals must be understood in order to minimize risks and control toxic hazards arising from the use of these compounds.

4.0931, REPELLENT ADDITIVES TO REDUCE PESTICIDE HAZARDS TO HONEY BEES

E.L. ATKINS, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (00ENTC10160519CA)

OBJECTIVE: Develop chemical repellents that would prevent bees from foraging in crops during the period of time a pesticide is applied or present.

APPROACH: Screen candidate compounds to determine comparative repellence for the honey bee. Determine whether contact or vapor chemical repellence is most effective. Test promising materials to determine the effectiveness of repellent formulations under field conditions. Determine the effects of the condition and attractiveness of the bloom of target crop and of competing adjacent crops and how they can be counteracted. Delimit the effects of temperature, relative humidity and light intensity on field performance of promising repellents. Study the possible phytoxicity of each candidate repellent.

4. PESTICIDES

SUPPORTED BY U.S. Dept. of Agriculture

4.0932, RESIDUES OF SELECTED PESTICIDES IN PLANTS, ANIMALS AND THE PHYSICAL ENVIRONMENT
T.R. FUKUTO, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-R0-SSE-1981-RR)

OBJECTIVE: Investigate the metabolism of new organophosphorus and carbamate insecticides in animals and plants, and determine the toxicological properties of their metabolic products.

APPROACH: New organophosphorus and carbamate insecticides under current development with unusual properties of specificity and toxicity will be selected for metabolism studies. Radiotracer preparations of the compound will be used to determine rates of absorption and translocation in plants. Metabolism in the house fly and white mouse also will be examined using radiolabeled compounds. Metabolic products will be identified using chromatographic, spectrometric and other chemical methods and by comparison with known compounds. Identified metabolic products will be examined for toxicity to insects and the white mouse, and for anticholinesterase activity.

PROGRESS: Studies are continuing on the metabolism of Stauffer R- 16,661, a new systemic insecticide. Two different batches of labeled R- 16,661 have been prepared in higher purity and metabolism studies have been carried out in the cotton plant. The most significant finding in this study was the amazing stability of R-16,661 in cotton. Analysis at different time intervals up to 51 days showed that the major portion of material isolated from the plant was unchanged R-16,661. Unequivocal proof for the structure of the material isolated as R-16,661 from cotton leaves was established by eventual isolation and purification of this material from methanol extraction of leaves by column and thin-layer chromatography and analysis of the product by NMR spectroscopy. Confirmation of the structure also was obtained by GLC. Three other metabolites also were detected by TLC with R(f) values of 0.0, 0.10, and 0.58. The materials at 0.0 and 0.10 are hydrolyzed products but the one at 0.58 is probably intact ester since it is an anticholinesterase. The metabolism of Monitor (Chevron's O-methyl S- methyl phosphoramidothioate) was examined in the house fly. Monitor proved to be exceedingly stable in the fly and the only compound which could be isolated and identified was Monitor itself. Evidently this material is not activated metabolically into other compounds. A GLC method applicable to the separation and identification of methyl parathion and paraoxon and their polar metabolites, including desmethyl and desaryl products, has been developed.

4.0935, PESTICIDE RESIDUES - THEIR NATURE, DISTRIBUTION AND PERSISTENCE IN PLANTS, ANIMALS AND SOILS
R.E. JOHNSEN, Colorado State University, Agricultural Experiment Sta., *Fort Collins, Colorado* 80521 (COL00237)

OBJECTIVE: The metabolism of pesticide residues by plants and micro-organisms as factors in modifying residue levels in food chains and in the environment. The effects of soil amendments such as sewage sludge and cattle manure on pesticide metabolism in Colorado soils will be studied.

APPROACH: Soil with and without soil amendments will be uniformly treated with 10 ppm of a chlorinated hydrocarbon insecticide such as DDT and aldrin. At intervals the soil will be analyzed for residues and metabolites using standard chemical methods including gas chromatography (GLC) to determine the rate of metabolism. If rapid degradation occurs, attempts will be made to isolate and identify the responsible micro- organism(s). Analytical methodology will be developed for materials which are non-pesticidal and known to interfere with GLC such as the chlorinated naphthalenes.

PROGRESS: An estimate of the extent and rate of metabolism of DDT by microorganisms was accomplished by aerobic incubation of 200 micrograms of the o,p'-and p,p'-isomers with 4 levels of diluted raw sewage in aqueous solution. After 1 week, the replicated solutions were extracted and analyzed by gas chromatography (GLC). At the highest sewage levels, 89 and 98% of the p,p'-isomer and 86 and 100% of the o,p'-isomer were metabolized. The principle metabolites were the respective TDE isomers. No evidence of either DDE metabolite was found. The existence of other metabolites not detected was indicated by the recovery rates decreasing with increasing sewage volume. Work on metabolism studies with sewage sludge has been hampered by interfering co-extractives with electron- capturing properties which obscure insecticide regions in GLC. The peaks resemble those obtained with chlorinated biphenyl compounds and come through normal clean-up procedures. The chromatographic behavior relative to aldrin of several chlorinated biphenyls (Aroclors) was studied by GLC using 2 columns because of their interfence with pesticide analysis. Results indicate means must be employed to separate these from pesticides.

4.0936, WEED CONTROL IN FRUIT CROPS, WITH SPECIAL REFERENCE TO APPLE AND PEACH
V.J. FISHER, Univ. of Delaware, Agricultural Experiment Sta., *Newark, Delaware* 19711 (DEL00104)

OBJECTIVE: Select the best timing of herbicide applications for maximum effectiveness, convenience and economy, determine the long-range effects of herbicides on growth and yields of fruit trees and on fruit quality. Study the plant ecology of orchards in which herbicides are used and measure the effectiveness of herbicide rotations and combinations in preventing unfavorable ecological changes.

APPROACH: Both preemergence and postemergence treatments of terbacil, simazine, diuron and dichlobenil will be made. Timing studies with paraquat as a supplementary spray will continue also, with paraquat being applied before, as well as with, the residual sprays of terbacil, simazine and diuron. Check trees will receive 'chemical mowing' only, using paraquat as needed. Data will be taken on yields, observable injury, weed control and fruit quality. New studies will be initiated on the ecology of orchards subjected to various weed control practices. Calculations will be made of species diversity and importance value.

PROGRESS: Studies were completed on the efficacy of three residual-type herbicides for controlling weeds in apple orchards, and on the most effective ways of using paraquat as a supplementary weed control agent. Terbacil was far superior to diuron, which in turn was superior to simazine. All three herbicides varied in the spectrum of weed species affected. Paraquat was effective whether used alone or in combination with residual herbicides. The use of paraquat greatly decreased the need for precise timing in the use of herbicides in orchards. An ecological study of peach orchards with different vegetational characteristics was conducted using different herbicide programs. In a minimal weed control area there was a high species diversity with low importance values for each species. Changing from a minimal weed control program to an effective herbicide program resulted in a decrease in species diversity and an increase in importance value for each species. The total number of plants in the area decreased with effective control measures. In areas of effective weed control there was a low species diversity, low total plant coverage, and high importance value for each species. When effective control measures were discontinued there was an increase in species diversity, an increase in total plant coverage, and a decrease in importance value for individual species.

SUPPORTED BY U.S. Dept. of Agriculture

4.0937, EFFECT OF PESTICIDES ON KEEPING QUALITY AND NUTRITIVE VALUE OF PLANT COMMODITIES
P. ROINE, Helsingin Yli. Helsing. Univ., *Helsinki, Finland* (SP43(E8-AMS-6(A)))

OBJECTIVE: Determine how postharvest pesticide treatments applied to improve keeping quality may affect storage life, chemical composition, food quality and nutrient content of plant commodities. Also, to study fate of pesticide residues, their metabolic and other disappearance routes and develop methods to determine residues.

APPROACH: Analytical methods will be developed to detect residues of CIPC, IPC, captan, malathion, diazinon and pyrethrins-piperonyl butoxide on various fruits, vegetables, grains and nuts for studies that include amount and specific kinds of pesticide residues and degradation products and where they are located in or on the product, effect of handling practices, processing reaction with plant constituents and rate of disappearance under different conditions, and biochemical and physiological background of important changes caused by residues in chemical composition, flavor, odor, color, appearance and nutrient content.

PROGRESS: Compositional changes in carrots take place during growth and storage following treatment with CIPC, linuron, and parathion. Carotene and sugar metabolism appeared to be affected. Changes in terms of technological or nutritional value of the plant commodities is assumed to be of minor importance.

SUPPORTED BY U.S. Dept. of Agriculture

4.0938, EFFECTS OF AERIALLY DELIVERED DEFOLIANTS AND INSECTICIDES
J.H. HUNTER, U.S. Air Force, Armament Laboratory, *Eglin Air Force Base, Florida* 32542

Technical Objective: The objective of this effort is to determine the long-range effects of repetitive aerial applications of military defoliants and insecticides on the natural environment of the target and adjacent areas. This objective is concerned with possible accumulation and persistence of spray materials that may be detrimental to plant and animal communities.

SUPPORTED BY U.S. Dept. of Defense - Air Force

4.0939, BASIC PHYSIOLOGY OF AQUATIC WEEDS IN THE SOUTHEAST
K.K. STEWARD, Florida Agric. Expt. Station, *Fort Lauderdale, Florida* 33310 (0710-02-05)

OBJECTIVE: Develop more effective and economical methods of controlling aquatic vegetation in waterways, canals, lakes, ponds in ways to minimize herbicide toxicity to the environment.

APPROACH: Study the growth requirements and patterns of aquatic plants as related to nutrition, light, temperature and other aspects of environment. Study life cycles and reproduction of aquatic weeds to determine optimum chemicals and times for control applications. Study the selectivity, absorption, and translocation of herbicides in plants and their persistence in the aquatic environment.

PROGRESS: Seven amine salt formulations of 2,4-D were evaluated in static water tests on the 2,4-D resistant submersed weeds Vallisneria and Egeria. The oleyl amine was most phytotoxic and a mixture of dodecyl-tetradecyl amines was next. Complete control was obtained at 5 ppmw in 2-4 weeks. A technique of applying herbicides to specific plant zones to increase effectiveness was assessed on the floating weed water hyacinth. Eight formulations of oil soluble herbicides were mixed in kerosene and applied to the root zone by floating the oil on the water surface. None of the treatments produced a phytotoxic response greater than the standard foliar application. Two silvex and one 2,4-D ester formulations were comparable at equivalent rates. Injury from diquat and amine salt of endothall applied to intact isolated stem regions of Hydrilla, Vallisneria, and Eurasian watermilfoil was restricted to tissue actually in contact with the herbicide. No translocation to other regions was apparent. Of 22 chemicals evaluated for effects on sprouting and regrowth of vegetation propagules of Hydrilla, dichlobenil was the most active. Shoot growth was completely inhibited at a concentration of 0.05 ppmw in continuous contact for 6 weeks. Herbicides incorporated into plastic pellets for slow controlled release into water were evaluated for phytotoxicity toward Eurasian watermilfoil. In static water tests a 0.1 ppmw rate of fenac acid produced 94% control in 8 weeks.

SUPPORTED BY U.S. Dept. of Agriculture

4.0940, ECOLOGY AND BIOCONTROL OF AQUATIC WEEDS IN THE SOUTHEAST
R.D. BLACKBURN, U.S. Dept. of Agriculture, Crops Research Division, *Fort Lauderdale, Florida* 33310 (0710-02-04)

OBJECTIVE: Develop effective and safe biocontrol methods of controlling aquatic weeds. Determine the effects of herbicides on biological control agents, fish, and other desirable organisms in the aquatic environment. Determine the changes in the aquatic environment when using biological, mechanical, and herbicidal control.

APPROACH: Study the life histories and ecology of biocontrol agents as related to the control of aquatic weeds. Conduct laboratory, growthpool, and field experiments to determine refinements in the most effective and safest techniques of utilizing biocontrol agents alone and in combination with herbicides for control of aquatic weeds. Evaluate in controlled environmental and field conditions the toxicity of herbicides to biocontrol agents, sports fish, and the aquatic environment.

PROGRESS: Hydrilla has replaced the submersed weeds southern naiad and Vallisneria in the freshwater canals and lakes of Florida. Regrowth in herbicidal treated areas is primarily from stem nodes and underground tubers. Diquat and paraquat were evaluated over a 3-year period in ponds to determine their effects on the fishery environment. The herbicide had an initial effect on the plankton but it recovered in 30 days after treatment. Diquat showed an acute toxicity to the amphipod Hyalella. Water quality was affected for a period of 10 to 14 days after treatment with both herbicides. Both herbicides could be used in the aquatic environment without long term effects. The Pomacea snail can be grown in the laboratory. Circulating water has been necessary for rapid growth. The snail feeds vigorously on aquatic weeds.

SUPPORTED BY U.S. Dept. of Agriculture

4.0941, AGRICULTURAL CHEMICAL RESIDUES IN PLANT AND ANIMAL PRODUCTS
H.A. MOYE, Univ. of Florida, Agricultural Experiment Sta., *Gainesville, Florida* 32603 (FLA-FS-00952)

OBJECTIVE: Development, adaptation and standardization of chemical, instrumental and biological methods of residue analysis. Investigate the behavior of chemicals as related to residues in agricultural commodities, and determine residues and their metabolites in agricultural commodities and in their environment.

APPROACH: Development of new and improved detectors for gas chromatography giving increased sensitivity and selectivity to pesticides. Enhancement of gas chromatographic response to carbamates by chemical modification. Improved extract cleanup with elution chromatography.

PROGRESS: New analytical procedures were developed for parathion on celery (phosphorimetry) and for Sevin on spinach, chicory and escarole (derivitization-E.C.G.C.) with limits of detection at 0.08 ppm and 1.0 ppm respectively. Speed is the primary advantage of these procedures over others. A D.C. discharge emission detector was evaluated for analysis of the organophosphate pesticides. Reliability and sensitivity were found to be superior to the microwave emission detector; selectivity over hydrocarbons was less, however. A modified flame photometric detector was constructed which did not extinguish upon sample injection and gave superior sensitivity and selectivity than the commercially available model. Florisil cleanup of aldrin, heptachlor epoxide, dieldrin and endrin was studied to determine elution solvent effects on oil retention. With comparable cleanup it was found that the oil capacity was strongly dependent on the elution solvent(s) used. A study in which the humidity, temperature and photoperiod of the environment surrounding rye grass

were studied for effects on dieldrin uptake showed that only humidity was involved. Low humidities enhanced uptake. Persistence studies and necessary modifications to analytical procedures were performed for Gardona on corn silage, Hercules 14503 on oranges and lemons, Azodrin on cabbage and Sevin with pinolene on potato and bean foliage.

SUPPORTED BY U.S. Dept. of Agriculture

4.0942, PESTICIDE RESIDUES AND METABOLITES
C.H. VANMIDDELEM, Univ. of Florida, Agricultural Experiment Sta., *Gainesville, Florida* 32601 (FLA-FS-01106)

OBJECTIVE: Provide data on pesticide residues remaining on or in Florida vegetables, subtropical fruits, pasture grasses, meat and dairy products.

APPROACH: Field treatment will include recommended dosage as well as 50-100% higher rate. Field sub-samples containing pesticides will be chopped and frozen until analyzed. Co-solvent extraction by blending in isopropanol and hexane or benzene will remove pesticide for biological material. Extracts will be cleaned up by elution through chromatographic columns. Chemical procedures approved by Food and Drug Administration employed wherever possible. Approved non-specific methods of analysis to establish practical cut-off periods for crops on compounds with established tolerance. Data also used to aid industry establish tolerance for a pesticide on crops of particular interest to the State of Florida.

PROGRESS: Torak residues remaining on oranges, grapefruit and lemons were determined following 2 spray applications 3 months apart. Torak residues over 1.0 ppm were detected in the peel of the oranges and grapefruit 84 days after the second application, whereas residues were somewhat less in the lemon peels 56 days after apraying. Although Niran 6-3 residues approached 5 ppm on sweet corn forage 5 days after 14 daily applications, the concentration on the shucked edible ear was only 0.01 ppm, which is far below tolerance levels for ethyl or methyl parathion. Insignificant residues of 2,4-D were found in both sweet corn fodder and the edible ears following one application to the actively growing crop. The following persistent pesticides were applied as bait or granular applications to rye grass either as a pre-plant or post-emergence treatment: trichlorfon, chlordane, diazinon and dyfonate. Most of the pre-plant treatments resulted in below 0.05 ppm residues in the rye grass except chlordane which was found in concentrations as high as 0.28 ppm following the 3.0 pound per acre application. The only exceptions were residues of dyfonate oxygen analog which were observed to peak between the 3 and 7 days following the post-emergence application to the rye grass. Most post-emergence pesticide treatments resulted in residues ranging from 0.15 ppm to 0.50 ppm 21 days after application to the rye grass.

SUPPORTED BY Florida State Government - Tallahassee

4.0943, REDUCTION OF HAZARDS ASSOCIATED WITH RESIDUES OF INSECTICIDAL CHEMICALS IN THE ENVIRONMENT
W.N. BRUCE, Univ. of Illinois, Agricultural Experiment Sta., *Urbana, Illinois* 61801 (ILLU-12-0317)

OBJECTIVE: Determine physical, biochemical, and biological factors influencing occurrence and persistence of insecticidal chemical residues in soils and agricultural commodities. Identify fundamental factors influencing magnitude of air and water pollution by insecticidal chemical residues. Develop basic studies related to the metabolism and detoxication of insecticidal chemical residues in animals, plants, soils and water. Identify effects of residues on ecosystems with emphasis on fish and wildlife. Influence of residues on soil microflora, microfauna, and non-insect fauna. Develop analytical techniques.

APPROACH: Study persistence, metabolism and detoxication of insecticide chemical residues in soils, plants, animals and water and study the effects of toxicant residues on ecosystems in soils and water.

PROGRESS: Methoxychlor, dieidrin, and furadan residues in the soil as they relate to the contamination of the aquatic environment are under investigation. Soil, pond silt, water, algae, and fish samples have been analyzed at weekly and monthly intervals following treatment of a watershed with these chemicals. Four days after a treatment with furadan at a rate of 4 lb. per acre and one day after a one inch rainfall, furadan was found in the pond water (.0167 ppm), plankton (2.957 to 4.839 ppm) and suspended silt and organic matter in one liter of water (2.465 to 3.873 micrograms). The analysis of all the fish and water samples has not been completed. Of special interest in the field experiment was the lack of reproduction in the Fairfield pond where dieldrin residues in fish ovaries and eggs were between 0.5 and 1.0 ppm. The water solubility of methoxychlor is higher than that of DDT. The reaction velocity of dehydrochlorination of methoxychlor (methoxychlor yields methoxy-DDE) is slower than that of DDT (DDT yields DDE) in water. Most of the methoxychlor, as with DDT, is adsorbed on sediment and silt in the water. However, significant amounts of methoxy-DDE were found in the water. Trace amounts of O,P - DDT are found in DDT-treated waters, but O,P - methoxychlor - DDE was not detected in methoxychlor- treated waters. Pond water and distilled water gave similar results.

SUPPORTED BY U.S. Dept. of Agriculture

4.0944, COMPARATIVE EFFECTS OF WEED COMPETITION, HERBICIDES AND OTHER WEED CONTROL PRACTICES ON PLANT RESPONSE
E.L. KNAKE, Univ. of Illinois, Agricultural Experiment Sta., *Urbana, Illinois* 61801 (ILLU-15-0364)

OBJECTIVE: Study plant response to herbicides, develop weed control systems adapted to the soils, crops and climate and specific weed problems of Illinois; develop weed control methods that will improve environmental quality for both desirable plants and humans.

APPROACH: Individual crop and weed response to herbicide placement in the soil will be studied. Since some weeds are more sensitive through shoot adsorption than root adsorption or vice versa, better control methods could result from studies on herbicide placement. New chemicals and chemical combinations will be evaluated for their performance in preplant, preemergence and postemergence weed control systems. Combinations of cropping systems, chemicals and cultivation will be used to develop control measures for nutsedge, climbing milkweed, common milkweed and wirestem muhly. Weed control methods will be developed that will minimize the potential for surface runoff of herbicides (minimum tillage) into water supplies.

PROGRESS: Greenhouse studies, to determine the extent to which morphological differences between plant species may serve as a basis for herbicide selectivity, will compare two grass species, Avena sativa with an elongating mesocotyl and Triticum vulgare without same. Field studies include the delineation of specific herbicide rates needed for control of specific weed species. Herbicide combinations with various ratios have been evaluated to improve consistency of performance and spectrum of control. Propachlor plus atrazine at 3 plus 1.6 lbs/A for surface application and butylate plus atrazine at 3 plus 1 lb/A preplant incorporated have been the two outstanding combinations for soil with 3 to 7 percent organic matter. Studies with low volume application equipment indicate feasibility for both liquid and wettable powder formulations. Calibration is more difficult than with conventional pressure systems. Evaluation of 13 granular formulations suggests considerable commercial potential for propachlor plus atrazine and alachlor plus atrazine. Use of herbicides for controlling vegetation in no-till systems indicates the feasibility of paraquat plus atrazine to kill fescue sod, but the need for translocated herbicides (2,4-D or dicamba) to control alfalfa.

SUPPORTED BY U.S. Dept. of Agriculture

4.0945, SOIL TOXICANTS, SOIL PHYTOPATHOGENS AND OTHER SOIL MICROORGANISMS
M.B. LINN, Univ. of Illinois, Agricultural Experiment Sta., *Urbana, Illinois* 61801 (ILLU-68-0349)

OBJECTIVE: Effect of toxicants including fungicides, nematocides and insecticides, on development of Endogone spp. Effect of toxicants on growth and/or metabolism of asymbiotic nitrogen fixing and nitrifying bacteria. Rate and extent of recolonization of the above soil microorganisms following treatment with toxicants.

APPROACH: Soil and plant roots containing Endogone spp. will be treated with several soil fungicides. Roots of appropriate host plants grown in treated and untreated soil will be examined for Endogone. Trichoderma will be introduced into soils that have been treated with pesticides. Persistence of Trichoderma will be determined. Effect of allyl alcohol on ability of Trichoderma to antagonize Rhizoctonia solani and other soil fungal pathogens will be evaluated. The effect of these pesticides on bacteria involved in nitrification and asymbiotic N- fixation.

PROGRESS: Growth of Trichoderma viride and Gliocladium fimbriatum was inhibited in culture by the fungicide Demosan at 25 ppm and by Plantvax and Vitavax at about 250 ppm. Further work with these 2 fungi was discontinued because of difficulty in crystallization of the antibiotics viridin and gliotoxin produced by the fungi. Nylon mesh discs (Nos. 263 or 275 Nitex) as transfer matrices for soil and other fungi were a marked improvement over nutrient agar plugs previously used by most investigators. The fungus on the disc can be placed in soil columns, removed afterwards and washed free from soil and fungitoxicants. A wide range of plant pathogens were successfully transferred. The growth of Gibberella zeae appeared to be stimulated by the nylon. This technique permits better separation of fungicidal and fungistatic properties of soil chemicals, and determination of actual concentrations of fungitoxicants required to inhibit fungal growth.

SUPPORTED BY: U.S. Dept. of Agriculture

4.0946, DETERMINE METHODS OF DIFFUSION OF IDEAS AND DO FURTHER DEPTH ANALYSIS OF DIFFUSION PROCESS

J.M. BOHLEN, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010 (IOW01320)

Progress: Studied and evaluated the adoption-diffusion process related to agricultural chemicals and the variables related to adoption- diffusion. Attention was given to the farmer adopters and dealers in the adoption-diffusion process. It is judged that the general, but at the same time limited objectives of the original project, were far exceeded as the project grew in scope and in depth during the period of the project. Of equal importance is the fact that this study provided many of the theoretical and methodological bases for more recent studies related to safe and effective pesticide use. While the vast majority of farmers possess favorable attitudes toward agricultural chemicals and their use and use of agricultural chemicals on their farms, their level of technical knowledge judged to be needed for safe and effective use is relatively low. Agricultural chemical dealer knowledge was also relatively low. Farmer's sources of information on agricultural chemicals: Awareness stage--mass media; Information stage--neighbors and friends; Evaluation stage--neighbors and friends; Trial stage--commercial. There were major differences in sources of information at each adoption stage by adopter categories--innovators to laggards. The dealer is not only a major source of information at the trial stage but apparently plays a major role in determining the chemical and brand of chemical used by the farmer.

SUPPORTED BY: Iowa State Government - Des Moines

4.0947, INSECTICIDAL CHEMICALS IN THE ENVIRONMENT

P.A. DAHM, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010 (IOW01686)

OBJECTIVE: Determine the fundamental physical, biochemical, and biological factors influencing occurrence, magnitude, interaction, and persistence of insecticidal chemical residues in soils and raw agricultural commodities. Develop basic studies related to the metabolism and detoxication of insecticidal chemical residues in animals, plants, soils, and water. Seek methods of removing or reducing residues of insecticidal chemicals from the environment. Develop and improve analytical techniques essential to the pursuit of this research.

APPROACH: Greatest emphasis will be placed on objective 2, by studying the metabolism of organophosphorus, carbamate, and chlorinated hydrocarbon insecticides in animals, plants, soils, and water. Differences between closely and distantly related species of animals and plants will be investigated as well as intraspecific factors such as age, physiological conditions, and environmental influences. The interaction of insecticides with other synthetic chemicals in our environment will also be explored.

PROGRESS: Two nitrogen-fixing soil microorganisms, Rhizobium japonicum and R. meliloti, were incubated with parathion in a phosphate buffer. Time course studies showed that parathion was rapidly metabolized in about 25 hours. Gas-liquid chromatography, thin-layer chromatography, and colorimetric analyses showed that reduction of parathion to aminoparathion was the major metabolic pathway. Aqueous fractions of S-parathion provided evidence that parathion was also being metabolized to 0,0-diethyl phosphorothioic acid. An oxidative enzyme system was evidently lacking since no paraoxon was found.

4.0948, WARNING AGENTS FOR TOXIC FUMIGANTS

E. BERGMANN, Hebrew University, *Jerusalem, Israel* (480A10ENT30(MQ))

OBJECTIVE: Develop nontoxic chemical warning agents to serve as indicators of the presence of methylbromide or other toxic fumigants.

APPROACH: Test compounds with irritant, sternutatory, or lachrymatory properties to determine whether their vapors produce an effect on man, at very low, nontoxic levels, that is strong enough to serve as a positive warning signal when they are added in small concentrations to methyl bromide. Test compounds that give promising results in the above tests to select ones that will not be absorbed and retained by foods or feed, not damage plants or seeds, and not corrode or otherwise harm structural materials, textiles, plastics, etc.

SUPPORTED BY: U.S. Dept. of Agriculture

4.0949, PESTICIDE RESIDUES IN MARKETING CHANNELS

A.M. KADOUM, Kansas State University, Agricultural Experiment Sta., *Manhattan, Kansas* 66502 (KAN00687)

OBJECTIVE: Reduction of pest damage or pesticide residues in agricultural commodities during transportation, processing and/or storage. Susceptibility of varieties of corn grain in storage to grain- contaminating and grain-damaging insects. Secure available corn varieties, strains and hybrids, from the corn germ plasm bank. Determine relative resistance of corn to representative pests. Determine reasons for resistance.

APPROACH: Corn varieties will be exposed to infestation. Screening will include rice weevils, confused flour beetle, lesser grain borer and Angoumois grain moth. Each variety tested for feeding, oviposition and progeny. Insects will be confined with the grain in containers to determine the type and extent of feeding damage. Radiographs will expose the activities of insects inside the kernels.

PROGRESS: Heat treatment of purified silica gel 950 (60-200 mesh) and 923 (100-200 mesh) in a muffle furnace at 130 C and 300 C for two hours was found to be the most effective for activation of silica gel for cleanup of pesticide residues from biological material with complete recovery of pesticides. A simple, aqueous acetonitrile partition cleanup method for analysis of insecticide residues has been developed. The partition characteristics of the insecticides used between hexane and two separate aqueous acetonitrile solutions (85%, 95%) were utilized. A starch-gel electrophoretic method to investigate esterase inhibition by common organic insecticides. Results indicate that aluminum lactate buffer at 0.038 M and pH 3.1 was the most satisfactory buffer system for resolving blood protein components of Tenebrio molitor larvae at a constant current of 45 ma (180 volts) for 25 hr. There was no significant difference between electrophorograms obtained from endrin-treated and control larvae.

SUPPORTED BY: U.S. Dept. of Agriculture

4.0950, EFFECTS OF HERBICIDES AND SOIL TOXINS ON RHIZOBIUM

E.P. DUNIGAN, Louisiana State University, Agricultural Experiment Sta., *Baton Rouge, Louisiana* 70803 (LAB01438)

4. PESTICIDES

OBJECTIVE: Determine the effects of selected herbicides and soil toxins upon the survival of Rhizobium japonicum grown in culture solutions, on agar plates and in soils. The ability of the bacteria to invade soybean roots and effectively fix atmospheric nitrogen in the presence of these materials will be evaluated.

APPROACH: Viability of Rhizobium japonicum grown in contact with selected herbicides will be determined on agar plates, in nutrient solutions and in herbicide-treated soils. Bacterial population numbers will be compared with non-herbicide-treated controls. The effects of the herbicides on the degree of nodulation of soybeans grown in selected media will be observed in the greenhouse and in field plots. Herbicidal effects on the symbiotic nitrogen fixation will be evaluated by observations of the plants for symptoms of nitrogen chlorosis, final yield data and plant-tissue analysis for total nitrogen. Newly-cleared soils within the state will be investigated in order to determine if a soil toxin is responsible for the poor and sometimes total lack of nodulation found. The soil organic matter will be selectively extracted and checked for the presence of compounds which are detrimental to the survival of the bacteria. The effects of soil amendments and soil pH on the degree of nodulation will also be determined. Tests will be made to determine if soil microorganisms are responsible for the death of Rhizobium japonicum in the problem soils.

PROGRESS: Greenhouse experiments with potted soils indicated that amiben, linuron, nitralin, trifluralin, vernolate, prometryne and GS16068 had no adverse effect on the nodulation of soybeans grown in Commerce loam soil. In Mhoon silty clay loam amiben had an adverse effect at the recommended rate as did linuron at twice the recommended rate. On Norwood silt loam, linuron, nitralin, prometryne and vernolate had an adverse effect on nodulation at recommended rates while all seven herbicides affected nodulation at twice the recommended rate. Field tests on Olivier silt loam indicated no adverse effects on the nodulation of soybeans from either pre-emergence or post-emergence herbicides applied at recommended rates. Pre-emerge herbicides included amiben, dacthal, GS16068, [illegible], linuron, nitralin, prometryne, trifluralin and vernam.

4.0951. PESTICIDAL RESIDUES IN FOODS

A.F. NOVAK, Louisiana State University, Agricultural Experiment Sta., *Baton Rouge, Louisiana* 70803 (LAB01390)

OBJECTIVE: Pesticide investigations will be made on various foods during the course of handling as they pass from the field to the table and into the nutritional pattern of the ultimate consumer, to ascertain if any health hazards exist.

APPROACH: Studies will be made on the following: Actual testing of seeds where applicable. Several stages during growth and cultivation. Comparisons will be made with the foods. Harvesting. What quantities of residues are present when the foods are removed from the soil, the vines or trees. Pre-processing storage. What quantities are degraded prior to processing. Processing foods. Foods will be analyzed during the various steps commonly employed for processing each food under investigation. Packaging. What problems and effects are encountered by employing various packaging materials and procedures. Distribution. What happens to residues during transportation, storage in warehouses, storage under various temperatures, etc. Retail outlets. Does long term handling result in residue changes or unusual modifications. Preparation of foods. Various methods of cooking, frying, mixing, etc. Consumption. What is the actual concentration, if any present at the time of consuming the food.

PROGRESS: The object of this project during the year has been to determine the amount of degradation of endrin in sweet and Irish potatoes from harvest through processing, storage, and to consumption. The possibility exists that certain types of processing will degrade insecticides and/or render their residues physiologically harmless for humans. One hundred pounds of each type of potato were procured locally and divided into four treatments: heat processed with and without water; blanched and frozen; and frozen. Prior to processing, the samples were washed, peeled, chopped, and placed in cans. One-half of each type of treatment was inoculated with endrin at a level of 1 mg /200 g. of sample. One-half of each process and inoculation treatment was irradiated with cobalt-60 at a dose of 750 Krads. All samples were tested for residual endrin at 0, 6, and 12 weeks of storage. Samples at 0 and 6 weeks retained residual amounts of endrin in all treatments. Quantitation is incomplete. The 12-weeks samples have not been analyzed as yet. A considerable amount of time was required to standardize the insecticide analyzer.

SUPPORTED BY: Louisiana State Government

4.0952. PESTICIDE RESIDUES IN OR ON RAW AGRICULTURAL COMMODITIES

R.L. KADUCE, Univ. of Maine, Agricultural Experiment Sta., *Orono, Maine* 04473 (ME00204)

OBJECTIVE: Investigate residues resulting from the use of pesticides and plant growth regulators applied to plants and animals, determine how to use these materials without undue residues in soil, water, and other parts of the environment. Standardize sampling and analytical methods for the determination of pesticide residues in or on agricultural commodities.

APPROACH: Investigate pesticide residues in and/or on apples, blueberries, potatoes, strawberries, poultry meat, and other selected vegetable and animal materials.

PROGRESS: To determine, in control of Red Leaf in blueberries, if 2,4-D would translocate from root to blueberries after burning of bushes and new plant growth interval. Replicates of five treated areas were examined. Six samples - none found; four samples - less than 0.03 ppm; 4 samples - range 0.039 to 0.104 ppm.

4.0953. FUMIGATED WHEATS--VITAMIN CONTENT OF PRODUCTS, BAKING PERFORMANCE OF FLOURS

E.M. HEWSTON, U.S. Dept. of Agriculture, Human Nutrition Research Div., *Beltsville, Maryland* 20705 (HN1-22)

OBJECTIVE: Effects of several types of wheat fumigants on tocopherols and B-vitamins of wheats, milling fractions, doughs, and baked products, and on eating quality of baked products.

APPROACH: Fumigate and sample hard red winter wheat, treated with 3 types of fumigant at intervals during 3 years storage, for total of 12 test periods. Mill to bran, shorts, low grade and patent flours. Prepare and bake bread and roll doughs from patent flours by 2 methods. Evaluate performance of flours and doughs and quality of bread and rolls. Analyze wheats and all products for residues, proximate composition, tocopherols, B-vitamins. Compare all measurements and analyses with those of control wheats. Correlate performance of flours in commercial and home-type breads with chemical components, physical measurements, taste panel evaluations of home-type breads and rolls, and fumigant residues.

PROGRESS: Results of physical tests on the control and fumigated flour samples such as hydrogen ion concentration, amylase activity, oil- binding capacity, color, and mixograph determinations as well as other tests submitted to Biometrical Services for statistical analyses. These analyses were completed and three manuscripts were prepared. All residue work was completed. Fumigation 8 times over a 3 year period has had no effect on total solids, fat, ash, tocopherols, or total B(6) contents of the wheat berry and the milling fractions from the wheat as determined by 12 samplings. Only 5 sampling periods selected for analyses for thiamine, riboflavin, niacin and 'bound' niacin for the wheat berry, milling fractions, bread and roll doughs, and baked breads and rolls. Tocopherols were determined on only certain selected samples of bread doughs, breads, roll doughs, and rolls. Wheat tocopherols in baked rolls and breads obscured by tocopherols in the shortening, and the fat used to grease pans. Increase in fat also observed in fat analyses. Evaluation of baking results for proximate composition not yet completed. No measurable loss of tocopherols due to baking; 80% retention of vitamin B(6) in breads and rolls after baking. Indications of baking losses for other B vitamins, but analytical results not completed.

SUPPORTED BY U.S. Dept. of Agriculture

4.0954, ANALYTICAL INVESTIGATIONS OF PESTICIDES AND THEIR RESIDUES
K.R. HILL, U.S. Dept. of Agriculture, Entomology Research Division, *Beltsville, Maryland* 20705 (00ENTM0301210200)

OBJECTIVE. Determine the amount, persistence, and fate of new insecticides or other insect control chemicals in crops, animals and animal products, and soils.

APPROACH. Obtain information, by analysis, on deposition, distribution, and persistence in plants, animals, animal products, and soils of residues from application of new chemicals being considered for insect control. Determine identity, amount, and fate of their metabolites or breakdown products in plants, animals, and soil. Analyze pesticide formulations to be used in experiments on insect control.

PROGRESS. Greenhouse-grown radishes and cress were exposed to dichlorvos at 1 gram active ingredient/1000 ft. for 7 days. No residues were found in radishes while the cress contained a maximum of 0.98 ppm after 16 hr. exposure. Greenhouse tomatoes were exposed to dichlorvos from 5% impregnated 8-mesh corn cob formulation either continuously or for 16 hr. nightly. Only a trace of dichlorvos was found less than 1 hr. after removal of continuous exposure and none was found 1 hr. after removal of the 16-hr. nightly exposure. Cuts of pork from various organs of swine fed diets containing heptachlor from 0.14 to 2.8 ppm were analyzed and found to contain residues of heptachlor epoxide from 0.0 to 5 ppm. Water and sediment soil from a well in Washington County, Md., was analyzed for pesticide residues and found to contain DDT (.05 ppb water, .04 ppm soil) and elemental sulfur (1.0 ppm soil). Four samples of beeswax foundation from Spain were analyzed and found to contain 1.0-2.0 ppm of DDT. Tomatoes, cucumbers, radishes, and leaf lettuce were exposed to the vapors from 1/8 oz. or 1/4 oz. of 42% calcium cyanide in 7000 ft. greenhouses. Cyanide found on the surfaces of tomatoes and cucumbers was below the detectable limit of 0.01 ppm. Tomato pulp contained an average of 0.35 ppm at the 1/8-oz. level and 0.19 ppm at the 1/4-oz. level while cucumber pulp averaged 0.43 ppm and radish pulp 0.14 ppm over the testing period. Lettuce averaged 0.21 ppm and 0.14 ppm from the 1/8- and 1/4-oz. treatments, respectively.

SUPPORTED BY U.S. Dept. of Agriculture

4.0955, CHLORINATED INSECTICIDE RESIDUES IN ANIMAL PRODUCTS AND FEEDS
W.A. MOATS, U.S. Dept. of Agriculture, Market Quality Research Div., *Beltsville, Maryland* 20705 (FC-86)

OBJECTIVE. Develop simplified procedures for detection and quantitative estimation of chlorinated insecticide residues in animal products and livestock feeds.

APPROACH. Study such commodities as dairy products, poultry and eggs, feed grains, forages, mixed livestock feeds, and animal by-products used in feeds. Pesticide residue analysis involves extraction, cleanup (separation of residues from interfering materials in the crude extract), and analysis to identify and quantitate the amount of pesticide residues present. Extraction and cleanup procedures for each commodity will be simplified as much as possible consistent with adequate recovery of pesticides and removal of interfering materials. Make final analyses by gas and thin-layer chromatography. Determine optimum conditions for these methods.

PROGRESS. Thin-layer plates incorporating vegetable oil and silver nitrate were found to be more color stable than other types of plates in which silver nitrate was incorporated. Plates incorporating only silver nitrate are unstable and it has therefore not been feasible to prepare them commercially since they cannot be kept for any length of time. The improved stability may make manufacture of commercial prepared plates feasible. The uniformity of the plates may also make it possible to analyze spots quantitatively using a thin-layer scanner.

SUPPORTED BY U.S. Dept. of Agriculture

4.0956, METABOLIC OBSERVATIONS - NUTRITIONAL INTERACTION BETWEEN UREA AND APPLE POMACE RE REPRODUCTIVE FAILURE
T.S. RUMSEY, U.S. Dept. of Agriculture, Animal Science Research Div., *Beltsville, Maryland* 20705 (03300551213?1)

OBJECTIVE. Determine if a biological interaction occurs between urea and the pesticide residues or ether extract portion of apple pomace within pregnant beef cows that is measurable by metabolic observations.

APPROACH. Two phases of experimentation will be conducted at Beltsville. Phase one will involve feeding apple pomace and urea to pregnant beef cows and quantitating changes in blood amino acids and minerals. The second phase will involve measuring blood residues in both the pregnant cow and her fetus to determine the proportion of pesticide residues which are absorbed by the fetus.

PROGRESS. Thus far, 10 of 11 cows fed apple pomace supplemented with cottonseed meal and 8 of 11 cows fed apple pomace supplemented with urea plus corn meal have calved. All of the calves from the cottonseed meal treatment were normal. Two of the calves from the urea treatment were born weak and died within 3 days. Preliminary summarization indicates the calves in the urea treatment at birth were less vigorous, weighed less and showed a tendency for less development of the metacarpus and the bones in the cartilage matrix. Diet did not affect serum copper in the cows but liver copper of the cows of the apple pomace-urea treatment was somewhat lower.

SUPPORTED BY U.S. Dept. of Agriculture

4.0957, EFFECT OF HERBICIDES ON PROVITAMIN A VALUE OF SELECTED RAW AND COOKED VEGETABLES
J.P. SWEENEY, U.S. Dept. of Agriculture, Human Nutrition Research Div., *Beltsville, Maryland* 20705 (HN10-06-02)

OBJECTIVE. Determine provitamin A values in selected raw and cooked vegetables as affected by use of herbicides during growth of vegetables, by changes occurring during cooking, and by biological availability when food is consumed.

APPROACH. The effects of amitrol or atrazine on biologically available carotenes will be determined in carrots, spinach and squash. Provitamin A values of these raw and cooked vegetables will be determined spectrophotometrically after chromatographic isolation of all-trans carotenes and their cis-isomers with lower biological activity. Cis-isomers of carotenes would be produced by household preparation of the vegetables, and possibly by herbicides. Amounts of biologically available provitamin A will also be evaluated by biological assay with rats.

PROGRESS. Arrangements have been made with the Crops Research Division, ARS, for growing carrots, spinach and squash treated with herbicides. Work has been carried out on the determination of the effects of preparation methods on the provitamin A content of fresh, frozen and canned vegetables, and on the conversion of all-trans-alpha carotene and all-trans-beta carotene to isomers with decreased provitamin A activity. A method has been developed for the determination of stereoisomers of alpha and beta carotenes. Results indicate that preparation methods for vegetables convert up to 35 percent of all-trans carotenes to stereoisomers, causing significant decreases in provitamin A content.

SUPPORTED BY U.S. Dept. of Agriculture

4.0958, OXIDATIVE DEALKYLATION OF PESTICIDES
R.E. MENZER, Univ. of Maryland, Agricultural Experiment Sta., *College Park, Maryland* (MD-H-090)

OBJECTIVE. Evaluate the in vivo mechanism of N-deethylation of the organophosphorus insecticide phosphamidon, and the N-demethylation of dimethoate and to characterize intermediates in those reactions. Develop a model in vitro system for the production of any oxidative methabolites detected in the in vivo work. Investigate the reactivity of the intermediates in oxidative dealkylation of these insecticides in relation to possible alkylation reactions in vivo.

4. PESTICIDES

APPROACH: The oxidative dealkylation of phosphamidon and dimethoate will be investigated using a variety of radiometric, chromatographic, and chemical degradation techniques. The insecticides, labeled in the phosphorus and N-alkyl groups, will be administered to rats, to ascertain the presence of metabolites. Characterization of the metabolites will be attempted. Liver microsomes will be prepared by differential centrifugation of liver homogenates, in an attempt to develop optimum conditions for production of metabolites.

PROGRESS: Dimethoate is converted to its oxygen analog in rats and plants. Both dimethoate and oxygen analog are subsequently oxidized to N-methylol derivatives which lose formaldehyde to give unsubstituted amide analogs. It was not possible to separate chromatographically the oxygen analog and N-methylol derivative of dimethoate, but positive identification of the latter was made by a derivative isotope-dilution procedure. Complete oxidative deethylation of phosphamidon has also been characterized. This compound undergoes reactions which successively oxidize the N-ethyl groups with subsequent loss from the compound, ultimately resulting in the phosphamidon unsubstituted amide. It has also been discovered that the vinyl chlorine of phosphamidon is replaced by a hydroxyl group by an unknown mechanism. This results in three additional neutral metabolites: vinyl hydroxyphosphamidon, des-N- ethyl vinyl hydroxyphosphamidon, and vinyl hydroxyphosphamidon amide. Identification of these new metabolites is based on chromatographic, isotope dilution, chemical, and radiometric data. No metabolism of organophosphates was found in whole cell or sonicated preparations of L- 929 of Chang liver cells. However, there are pseudocholinesterase-type enzymes present, which organophosphates inhibit at high levels.

4.0959, PESTICIDE RESIDUES IN OR ON RAW AGRICULTURAL COMMODITIES

F.R. SHAW, Univ. of Massachusetts, Agricultural Experiment Sta., *Amherst, Massachusetts* 01002 (MAS00058)

OBJECTIVE: Determine composition and persistence of pesticide residues on forage, fruits, and animal products.

APPROACH: Pesticides will be applied at different periods during the growth cycle and residues determined chemically.

PROGRESS: Research on residues of Rabon resulting from feeding of various formulations to poultry are well underway and will be continued. Comparisons of residues resulting from application of two formulations of Imidan to alfalfa have been determined. Residues of pesticides on cranberries and blueberries have been conducted at the Cranberry Station.

SUPPORTED BY U.S. Dept. of Agriculture

4.0960, PHYTOTOXICITY OF MSMA RESIDUES AND ARSENIC CONTENT OF FOODS

W.L. BARRENTINE, Delta Branch Experiment Sta., *Stoneville, Mississippi* 38776 (0710-11-02(CA))

OBJECTIVE: Determine the effect of simulated accumulations of arsenic from monosodium methanearsonate (MSMA) upon phytotoxicity to tolerant and susceptible crop plants; assess effect of arsenic residue upon crop quality and yield and upon arsenic content of the edible portions; determine arsenic movement in soil and influence of iron and aluminum content of soil upon arsenic activity.

APPROACH: Plots high and low in iron and aluminum will receive a single incorporated application of a range of dosages of MSMA to simulate short- and long-term accumulations of the arsenic herbicide. Cotton, soybeans, rice, potatoes, and snapbeans will be planted each year, and response will be rated visually and by measurement of yield and quality. Transport of arsenic in the soil will be determined by bioassay and other analyses. Edible portions of the crops will be analyzed for arsenic content.

PROGRESS:

4.0961, EFFECTS OF PESTICIDES ON PROTEIN, CARBOHYDRATE, AND NUCLEIC ACID METABOLISM. INTERACTION BETWEEN MICROORGANISMS AND PESTICIDES

B.T. JOHNSON, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Preliminary investigations will be initiated utilizing a selected group of yeast, bacteria and protozoa to ascertain the influence pesticides play in basic respiration and synthesis. Fundamental work will involve development of suitable radio-respirometry and disc electrophoresis technique.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0962, ANALYTICAL LABORATORY

C.W. GEHRKE, Univ. of Missouri, Agricultural Experiment Sta., *Columbia, Missouri* 65201 (MO00132)

The major objectives of the Experiment Station Chemical Laboratories are to conduct analytical chemical services and research on chemical methods for the College of Agriculture and Experiment Station. The research concerns development of new, improved, automated and instrumental methods and basic research in Agricultural Chemistry. Analyses were: Fertilizer 31,500; ASCS limestone 6150; general assays for College of Agr. 17,050; other general assays for service and research 3000. Specilized analyses: 2500 lysine and 400 methionine by automated colorimetric methods; 1500 gas chromatograms including service and method development; 200 lysin, 50 multiple amino acids, and samples for nucleic and fatty acids; 200 samples for amino acids by automated ion- exchange; 10 analytical ultracentrifuge samples; 50 lyophilizations; 50 samples for pesticide residues. Total assays 62,410. Research was continued on development and automation of methods, especially in fertilizers, pesticides, amino acids, and protein chemistry. A major accomplishment was compiling and publishing the book listed as the second item in the publication list. Dr. Gehrke served as AOAC General Referee on limestone and Assoc. Referee on sampling of fertilizers. Mr. Rexroad served as AOAC Assoc. Referee on nitrogen in fertilizers and mechanical analysis of limestone. A continuation of the major objective is planned for next year.

SUPPORTED BY Missouri State Government

4.0963, TRACE LEVELS OF PESTICIDE RESIDUES IN AGRICULTURAL COMMODITIES IN MARKETING CHANNELS

D.D. HEMPHILL, Univ. of Missouri, Agricultural Experiment Sta., *Columbia, Missouri* 65201 (MO00573)

OBJECTIVE: Study the effects of pesticides on acceptability and/or nutritive value of agricultural commodities. Develop procedures for the removal reduction or de-toxification of pesticide residues and conversion products in agricultural commodities. Develop or improve methods for the determination of pesticide residues in agricultural commodities in marketing channels.

APPROACH: As studies are completed with the chlorinated hydrocarbons (organochlorine) emphasis will be shifted to organophosphate and carbamate pesticides.

PROGRESS: Commercially grown tomatoes sprayed with malathion were used to determine the effects of certain preparative and processing treatments on pesticide residues. Ethyl acetate extraction and sweep co-distillation methods along with alkali-flame gas chromatography were used to determine residues. Water rinsing removed 28% while buffing removed 69% of the residue. Most of the malathion residue was on or absorbed in the peel. Peeling gave a 98% reduction in malathion residue. Boiling resulted in a 62% and a 10 hr. exposure to UV light gave 81% reduction. Diazinon, Malathion and parathion in ethyl acetate solution were subjected to 90,000 Rad Cobalt 60 radiation. There was a 41% reduction in diazinon, 49% reduction in malathion and 59% reduction in parathion. DDT, DDD and DDE standards in hexane solution exhibited losses od 32, 36 and 59% respectively. An improved alkali flame detector system using purified rubidium sulfate and anode of new design was developed

and optimized for the quantitative determination of organophosphate pesticides. Under optimum conditions sensitivity of one picogram was achieved. The detector life with an average of 27 injections of sample extracts and standards per day was more than 90 days and cleaning of the electrode and detector cell were not necessary during this period.

SUPPORTED BY U.S. Dept. of Agriculture

4.0964, EVALUATION OF PESTICIDE RESIDUE PROBLEM IN MONTANA

J.C. BOYD, Montana State University, Agricultural Experiment Sta., *Bozeman, Montana* 59715 (MONB00165)

OBJECTIVE: Evaluate pesticide residue problem, conduct necessary research to determine plant uptake and contamination, determine practices to prevent build up of residue in animal tissue and milk and reduce residue levels in animal tissues and milk.

APPROACH: Literature review and consultation, location of residue in soil and ground cover, determination of residues in hay and forages with various treatment histories, determine effect of flaming contaminated areas on volatilization of residue, measurement of translocation of residue and pesticide by plants, and measurement of decay curve of pesticide from animal tissue and milk.

PROGRESS: Montana experienced a pesticide problem in milk as a result of chlordane being used to control adult alfalfa weevil. Some 30 dairymen were restrained from selling milk and some 1500 cattle quarantined. All dairymen are now back on the market and all cattle have been released. Data relative to rate of decline of residue in the milk after feeding contaminated hay has been collected. Relationship of residue in milk fat as related to body fat, residue in soil and crowns of alfalfa plant to foliage of plant have been determined. Translocation of chlordane from soil to alfalfa foliage has been demonstrated. In recent months the so-called heptachlor epoxide level has been shown to contain other components, as yet unidentified. Samples of contaminated milk have been supplied to Food and Drug Research Laboratory in Washington D. C. for work in this area. The problem is largely over. Five progress reports have been written for use of staff, and extension personnel.

4.0965, BIOLOGICAL INTERACTIONS WITH SYSTEMIC FUNGICIDES

D.E. MATHRE, Montana State University, School of Letters, *Bozeman, Montana* 59715

With the people and governments of the world becoming more and more concerned about the use of pesticides and the potential contamination of our environment with pesticide residues, it becomes extremely important to know the ways in which pesticides interact with and affect biological systems. This investigation will be concerned with a study of a new group of organic fungicides, the oxathiins, that have the unique property of being systemic in higher plants.

The main objectives will be concerned with determining how these materials interact with various biological systems so that we may better assess the potential danger from residues of these materials in our environment. Experiments will be conducted to provide information in the following areas: 1) The mechanisms of uptake and movement of the oxathiins through higher plants, 2) the effects of the oxathiins on the metabolism of higher plant cells, resistant and sensitive fungi, 3) the reasons for the specificity of the oxathiins for the Basidiomycetes, 4) the ability of higher plants to metabolize or transform the oxathiins to other compounds, 5) the metabolism or transformation of the oxathiins by various microorganisms, 6) the longevity of the oxathiins in plant residues and the factors affecting their decomposition. At present there is little information available on any of the above areas.

4.0966, BIOLOGICAL DEGRADATION OF AGRICULTURAL PESTICIDES

C. STILL, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00508)

OBJECTIVE: Investigate the enzymic mechanisms and pathways of biological degradation of pesticides.

APPROACH: We propose to determine with the aid of zonal centrifuges the intracellular localization of enzymes which might participate in the biological degradation of pesticides. We expect to purify these enzymes so as to determine such characteristics as substrate range and specificity, rate of pesticide transformation and the chemical nature of the products formed. We propose to explore the development of continuous-flow zonal rotors for the concentration of plankton from fresh waters. If successful, this procedure would permit precise estimates on the amounts of pesticides and their transformation products accumulating in phyto- and zoo-plankton. Molecules of special interest will be those structurally related to the acylanilides.

PROGRESS: Studies on the propanil amidase of rice plants have been continued. The enzyme is associated with particles showing many characteristics of mitochondrial fragments. Propanil is an inhibitor of the Hill reaction and photosynthesis in green plants. We find that it is also a growth inhibitor in a non-green plant (dark-grown Euglena gracilis) and the slime mold Physarum polycephalum. We have not demonstrated the conversion of dichloroaniline (DCA) to tetrachloroazobenzene (TCAB) in rice plants. We have compared peroxidases from rice, barnyardgrass, and horseradish and find that the enzymes of rice and barnyardgrass, unlike horseradish, do not convert DCA to TCAB. TCAB is a highly toxic, stable metabolite of propanil and DCA in soil. We find that TCAB is without lethal effect in the slime mold, indeed some growth stimulation may occur. However, we have been unable to obtain evidence of metabolic breakdown of the parent compound.

4.0967, INSECT REPELLENT RESEARCH

UNKNOWN, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00475)

Two general approaches may be taken in repellent research--screening candidate compounds and attempting to improve known repellents which have certain inherent advantages. The latter approach was emphasized in 1968 to improve ethylhexanediol. Criteria for upgrading such a repellent are by increasing resistance to wear, improving ease of application, improving consumer acceptance by reducing heating of skin or respiratory irritation, and by increasing the number of annoying insects against which protection can be assured. During the past year 40 formulation comparisons including 219 duration tests were conducted in the laboratory, and 16 formulation comparisons including 74 duration tests were conducted in the field. Repellent testing methods and tools used in repellent studies have been critically reevaluated. A concentration testing method is being developed to complement the duration testing method by determining the threshold concentrations at which repellents are effective and thus reduce the man-hours involved in each test. In addition, two testing tools are presently under development. A cylindrical test cage is being studied to improve the handling of bioassay organism and visibility for the tester, and to reduce experimental error from accidental rub-off and uneven wear of the repellent. A 'bite-o-meter' using electronic recording may find future use for screening several compounds simultaneously, reducing human observational errors and influences, and permit testing with less costly pharmacological studies.

SUPPORTED BY New Jersey State Government - Trenton

4.0968, BIOASSAY OF SUCKER CONTROL CHEMICALS AND PESTICIDE RESIDUE ON LEAF TOBACCO

F.G. BOCK, Health Research Incorporated, *Buffalo, New York* 14203 (709-053-A103(C))

OBJECTIVE: Determine the possible threshold carcinogenic activity, if present, of sucker control chemical including penar, maleic hydrazide, methyl caprate, 1-octanol, 1-decanol, Tween-20 and Tween-80, and leaf extract from green and cured tobacco with or without field pesticide treatment.

APPROACH: Establish the dosage response relationship in tumor promoting ability of sucker control chemicals and the highest negative response level. Penar, maleic hydrazide, T-43, T-

148, Tween-20, Tween- 80, and possibly radiocarbon-labeled Tween compounds are tested separately or in combination through topical application to the shaved backs of animals. Make extracts of green and cured leaf tobacco samples produced in the field with or without pesticide treatment. Fractionate into soluble and insoluble fractions for bioassay as above. At the end of the test period, animals showing evidence of tumor formation and/or associated pathological changes will be sacrified, and autopsies, including histological examination, will be performed to determine the possible threshold level of these compounds.

SUPPORTED BY U.S. Dept. of Agriculture

4.0969, TOXICOLOGY OF FOREST INSECTS OF THE SOUTHEAST

F.L. HASTINGS, U.S. Dept. of Agriculture, S.E. Forest Experiment Station, *Durham, North Carolina* 27709 (SE2206)

OBJECTIVE: To acquire basic knowledge of the toxicology of forest insects as a basis for safer, more effective chemical control methods.

APPROACH: Systemic insecticides; uptake, translocation, deposition, toxic activity and metabolism by trees. Effectiveness of organic insecticides, under varying environmental conditions - humidity, heat, soil moisture and soil acidity - will be determined. Use of adjuvants to include wetters, spreaders, extenders, stickers and synergists. Penetrants affecting uptake of systemics; effectiveness of conventional poisons. Evaluate toxic properties of the parasporal bodies of Bacillus thuringiensis terpenes and polyphenols. Study other physiologically active chemicals and their mode of action.

SUPPORTED BY U.S. Dept. of Agriculture

4.0970, HEALTH-RELATED FLUE CURED TOBACCO RESEARCH IN NORTH CAROLINA

J.F. CHAPLIN, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (0500-03-16(CA))

OBJECTIVE: Develop chemical disease control methods leaving no metabolic products or residues harmful to the consumer.

APPROACH: Evaluate combinations of resistant varieties and new pesticide chemical formulations such as a mixture of 80% dichloropropene, 15% chloropicrin, 5% propargyl bromide; or 80% 2- methyl-2-2 (methylthio) propion and 20% aldehyde-0-(methylcarbamoly) oxine on control of brown spot, black shank, nematodes, and black root rot of flue-cured and burley tobacco. Yield and quality performance will be determined Residue determinations and bioassay studies of smoke condensate will be performed from leaf produced under successful treatments.

PROGRESS: Tests conducted in critical problem fields showed the value of high resistance in reducing losses to black shank, Granville wilt and black-root-rot in flue-cured tobacco and black-root-rot in burley tobacco. The average value of high resistant varieties in black shank test was $146 more than that of moderate, $253 above low, and $730 more than that of susceptible varieties. For bacterial wilt the performance of high resistance varieties increased in value over those that were moderate and low by $270 and $464 per acre respectively. Sps G-7 and G- 28 were the only flue-cured varieties that appeared to have resistance to black-root-rot. Ky 12 and 14, burley varieties with high levels of black-root-rot resistance, produced $420 per acre more than the low resistant Bu 21, and $1663, above the susceptible varieties. Nematicides, containing Ethylene dibromide, were the only ones from 25 nematicides tested, that provided sufficient control of all four species of root-knot nematodes (M. incognita, new race of incognita, javanica, and arenaria). Nicotine and sugar levels of tobacco treated with different chemicals were only slightly affected, however, tobacco produced on plots treated with halogenated chemicals was generally higher in total halides than the checks.

4.0971, CONTROL OF URBAN AND INDUSTRIAL PESTS

H.B. MOORE, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC03252)

OBJECTIVE: Establish, by means of surveys, the distribution, abundance, and economic importance of urban and industrial pests in North Carolina. Improve the safety and effectiveness of the control of these pests through the evaluation of chemicals and application techniques, old and new.

APPROACH: The surveys will be accomplished by making systematic collections across the state and by examing the collection records in museums and the control records of pest control firms. Evaluate techniques and chemicals for control; replicated tests will be conducted in infested buildings and in the laboratory.

PROGRESS: Initiated project with Raleigh Housing Authority, Shell Chemical Co. and Surety Exterminating Co. to determine cockroach control using Vapona (Reg) mini-strips in enclosed cabinets of low-rent housing. Data analysis incomplete. (C.G. Wright) Survey on old house borer distribution in the state, and the reasons for its increase, was initiated but no data has reached the reportable stage. (H.B. Moore)

4.0972, AGRICULTURAL CHEMICAL RESIDUES IN PLANT AND ANIMAL PRODUCTS

T.J. SHEETS, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC01022)

OBJECTIVE: Development, adaptation and standardization of chemical, instrumental and biological methods of residue analysis. (Methodology) behavior of chemicals as related to residues in agricultural commodities. (Behavior) residues and their metabolites.

APPROACH: Pesticide residue analysis in support of commodity research projects. Research in the area of pesticide residue analysis. Breakdown of pesticides in environment studied.

PROGRESS: Studies on uptake of chlorinated hydrocarbons from soil by oil-seed crops were continued. Levels of dieldrin in seeds of peanut and soybean increased linearly with rate of application and varied with location. Peanuts can become contaminated to levels exceeding the FDA action level from relatively low levels of the insecticide in soil at planting. In chicks with a high body burden of DDT, administration of low levels of Protamone increased the rate of conversion of DDT to DDE. Seventy-two hours after feeding DDT to quail, adipose tissue contained greatest concentrations, but relatively high levels were found in liver and muscle tissue. DDD was present in greatest proportions in the liver. Dieldrin levels in milk fat of two dairy cows decreased from 55 to 0.4 ppm in a 5-month period. One year after the last application, residues of dichlobenil, terbacil, and DP-733 in soil were greater on incorporated plots than on plots that received surface applications. Persistence was greater with incorporation. Carbofuran was converted to 3-hydroxy carbofuran in young tobacco plants. Its concentration reached a peak in 8 days and declined. Small amounts of other metabolites were found. These results show that pyrolysis during cigarette smoking of 3-hydroxy carbofuran as well as the parent pesticide, carbofuran, should be determined.

SUPPORTED BY U.S. Dept. of Agriculture

4.0973, IMPORTANCE OF FEED AS AN UNAVOIDABLE SOURCE OF PESTICIDE CONTAMINATION IN POULTRY MEAT AND EGGS

E.C. NABER, Ohio State University, Agricultural Experiment Sta., *Columbus, Ohio* 43210 (OHOSS-160)

OBJECTIVE: Survey commonly used feedstuffs for their pesticide content in order to determine levels of contamination from dietary sources. Determine the amounts of residue in meat and eggs from feeding the levels found in natural feedstuffs.

APPROACH: Samples of corn, soybean meal, alfalfa meal, fishmeal, and fat will be obtained on the open market, or from processing plants. Five samples of each feed ingredient from each area shall be collected randomly each month for 24 months. Composite samples of each feed ingredient for each area will be analyzed monthly for DDT, DDE, DDD, aldrin, dieldrin, heptachlor, methoxychlor, toxaphene, and lindane. In addition, day-old broiler chicks in groups of at least 10 chicks each will be fed diets formulated to contain the three levels of the pesticides as indicated above. These birds will be slaughtered at 8 weeks of age and pooled samples of liver, muscle and fat taken for residue anal-

ysis. In addition, samples of eggs from other groups will be analyzed at 1, 2, 4, 6, 10, 16, 24 and 32 weeks for the above residues.

PROGRESS: Poultry feed ingredients were analyzed for their content of 10 organochlorine pesticides. 688 samples have been analyzed. Egg samples have also been analyzed. DDT and its metabolites were the most frequently found contaminants in all poultry feed ingredients. Residues of aldrin were found frequentiy in soybean and corn meal. Heptachlor expoxide and aldrin were occasionally found in alfalfa meal. Aldrin, lindane, and dieldrin occurred frequently in fish meal and fat. The range of residue concentrations in the feed ingredients was considerable. Although pesticide residues were common in all types of feed ingredients, the highest concentrations found during the past year were: heptachlor, 0.13 PPM in alfalfa meal; aldrin, 8.4 PPM in fat; DDE, 0.533 PPM in fishmeal; DDD, 0.603 PPM in corn meal; and methoxychlor, 0.149 PPM in corn meal. Lower concentrations of residues ranging down to zero were found in all five ingredients.

4.0974, THE CYCLING OF CL-36 LABELED DDT IN NATURAL ECOSYSTEMS

T.J. PETERLE, Ohio State University, School of Arts, *Columbus, Ohio* 43212 (AT(11-1))

Prior experience in the use of isotope-labeled pesticides has demonstrated that this is a useful and economical way for determining the transfer of these organic compounds in ecosystems. This project will attempt to determine the transfer of the Cl-36 DDT through a terrestrial system. Radioassay procedures will be used to qualify the level of the insecticide and its metabolites in the various physical and biological components of the ecosystem. Since the radioassay procedures will assess only the labeled DDT applied, total body burdens will reflect only that DDT accumulated from the study area. Some artificial exposures in time and space will be made to determine rates of accumulation for the various species present on the treated area.

SUPPORTED BY U.S. Atomic Energy Commission

4.0975, PESTICIDE STRESS EFFECTS ON EXPERIMENTAL ECOSYSTEMS

G.W. BARRETT, Miami University, School of Arts, *Oxford, Ohio* 45056

The investigation will deal specifically with plant, arthropod and small mammal components within eight 1/4-acre fenced enclosures.

The design of the experiment allows for the comparison of a pesticide stress on two kinds of ecosystems of major interest to man, namely a cultivated monoculture ecosystem and a natural 'oil-field' ecosystem.

Ecologists are still seeking good criteria to measure the resilience and regulatory powers of an ecosystem when such systems are treated with stressors, such as pesticides. A study of this nature will discover and evaluate such criteria.

SUPPORTED BY U.S. National Science Foundation

4.0976, FEED AS A SOURCE OF PESTICIDE CONTAMINATION IN POULTRY MEAT AND EGGS

E.C. NABER, Ohio Agric. Res. & Dev. Center, *Wooster, Ohio* 44691 (032900170137)

OBJECTIVE: Survey five feedstuffs for pesticide content and determine levels of residues in meat and eggs from feeding levels found.

APPROACH: Samples of corn, soybean meal, alfalfa meal, fishmeal and fat will be obtained on the open market. Five samples of each of these materials shall be collected randomly each month for 24 months and composite samples of each feedstuff for each area will be tested for DDT, DDE, DDD, aldrin, dieldrin, heptachlor, methoxychlor, toxaphene and lindane. Selected levels, based on analytical results will be fed and residues determined in meat and eggs.

PROGRESS: A total of 1128 samples of feedstuffs were collected during the reporting period. Pesticide residues were determined in 688 of these samples. The feeding study of pesticide-fortified feedstuffs to laying hens was completed and residue analyses of 314 samples of eggs have been made. Samples of fat, muscle and tissue were collected. Traces of dieldrin and DDE appeared to be common contaminants in all egg samples. Most of the residues in feedstuffs were present in trace amounts and were reported in ppb. The major residues found are as follows: soybean meal -- aldrin, DDE, pp' DDT, lindane and dieldrin; corn -- aldrin, pp' DDT, lindane; alfalfa -- all pesticides tested for were present, with aldrin, DDT and its isomers, lindane and dieldrin predominant; fishmeal -- essentially the same as alfalfa; fat -- DDT and its isomers, lindane and dieldrin.

SUPPORTED BY U.S. Dept. of Agriculture

4.0977, REDUCTION OF HERBICIDE RESIDUES

A.P. APPLEBY, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00732)

OBJECTIVE: Find herbicides which are more effective at lower rates, less toxic to humans and animals, less injurious to desirable plants, and less persistent in the soil. Develop methods of increasing the effectiveness of present herbicides so that dosages required for adequate control may be reduced, thus reducing residue levels.

APPROACH: Laboratory, greenhouse, and field experiments will be conducted to accomplish the above objectives. Use of combinations to reduce total amount of herbicide per acre, use of adjuvants to increase effectiveness, study of controlled-release of short-residual materials by granular coatings, encapsulation, etc. and study timing applications for maximum control at minimum rates.

PROGRESS: Research on herbicide combinations for corn has largely been concluded. Results indicate that any of 4 herbicides effective against grass (EPTC, butylate, propachlor, or alachlor) combined with any of four herbicides effective against broadleaves (atrazine, S-6115, dinoseb, or 2,4-D) effectively and safely control a wide range of annual weeds in corn in Oregon. The use of these combinations has led to a reduction in the rates of persistent type herbicides at the same time that weed control has improved. Application of atrazine in oil for postemergence weed control in corn appears to reduce the rate requirement even further. However, the application must be made before weeds reach more than two inches in height. Extensive tests for postemergence applications of sinbar terbacil for weed control in peppermint have shown promise for reducing the rates of that material required. This may lead to consistent weed control with less chance of injury to rotation crops. Surfactants added to terbacil increased its effectiveness, but little difference could be noted between the various surfactants tested. Non-phytotoxic oils were more effective in increasing terbacil activity from either surfactants or liquid fertilizer. At least one major herbicide in each family of herbicides was found to stimulate plant growth when applied at sublethal doses. This seems to point to a general biological phenomenon since the mechanisms of action of the herbicides tested vary widely.

SUPPORTED BY U.S. Dept. of Agriculture

4.0978, TOXICOLOGY OF PESTICIDES IN THE ENVIRONMENT

V.H. FREED, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00674)

OBJECTIVE: The approach used in this study is a coordinated, interdisciplinary type of investigation. It involves entomologists, pathologists, pharmacologist, ecologists, analytical chemists, physical chemists, biochemists and mathematicians. The study attempts to assess the current behavior and persistence of pesticides in the environment, the transport across interface between the environment and organisms or uptake, the pharmacodynamics and effects of various levels of organization in the biological system. This will include effects at the molecular level through the whole animal and the effects studied consist both of metabolism by the organism and the effect of the xenobiotic on metabolism and function in the organism. An important feature of

the study is the involvement of analytical chemists in all phases of the work. A central analytical facility is available to assist in development of new methods and the quantitation of pesticide and metabolites in the studies.

APPROACH: NOT-PROVIDED

PROGRESS: Progress has been made in the following areas: Uptake of chemicals from the environment by food chain; analytical chemistry of pesticides including analyses of a number of research standards; metabolism of pesticides by intact organisms as well as isolated systems of enzymes; chemodynamics in the environment; the effect of xenobiotics on metabolism of organisms; effect of xenobiotics on behavioral responses.

SUPPORTED BY Oregon State Government

4.0979, PESTICIDE RESIDUES

V.H. FREED, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00284)

OBJECTIVE: Determine the rates of metabolism of selected pesticides in plants, animals and soil. Ascertain the nature of the metabolic transformation products of pesticides. Develop methods of analysis for pesticides and their degradation products in soil and biological tissues.

APPROACH: The procedure for accomplishing these objectives will be to treat plants, animals or soil with selected pesticides. Radiolabeled pesticides will be used when they are available to facilitate determination of metabolic pathways. After varying periods of time, the treated substrate will be analyzed to determine the amount of parent pesticide remaining. The metabolites will be isolated and their identity determined by means of adsorption- and gas chromatography and mass- and Infrared spectroscopy.

PROGRESS: The metabolism of the herbicide 2,6-dichlorobenzonitrile (dichlobenil) by soil and cranberry plants was studied, The rate of metabolism of the herbicide in soil is relatively slow, its half-life being nearly 4 months at 80 C. The energy of activation for the decomposition is about 4 Kcal/mole. Since the effective soil life of dichlobenil is considerably shorter under field conditions, it is apparent that volatility losses are appreciable. Cranberry plants readily absorb and metabolize dichlobenil. The metabolites of the herbicide are conjugated with plant constituents. Hydrolysis under alkaline or acid conditions yields two metabolites. These two metabolites were identified by mass spectral analysis and found to be 3- hydroxy-2,6-dichlorobenzonitrile and 4-hydroxy-2 6-dichlorobenzonitrile. However, no detectable residues of either of these metabolites were found in cranberries from fields treated with 6 lbs/acre of herbicide.

SUPPORTED BY U.S. Dept. of Agriculture

4.0980, CENTER FOR ENVIRONMENTAL MANAGEMENT

V.H. FREED, Oregon State University, School of Agriculture, *Corvallis, Oregon* 97331

The Environmental Health Sciences Center at O. S. U. has been in operation a little over two years. In this time a program of research and training on environmental problems has been initiated. Further, the center has contributed to the crystallizing and focussing of interest and work on this campus concerned with environmental problems.

The renewal proposal emphasized the role of the Center in research and training in a coordinated effort on the environmental health aspects of microchemical pollutants. Attention will be given; (1) the identification and inventorying the various environmental chemicals (2) study of the dynamics of distribution and (3) their biological effects, made of action and metabolism. The objectives of the program are: 1. To identify critical environmental health problems, conduct research on selected problems and stimulate and encourage research on others, 2. To provide training with specific environmental health orientation to students and to encourage their commitment to this important area of work, 3. To facilitate the research and training through planning, coordination and provision of research support service and facilitate the dissimination and utilization of the research findings.

4.0981, INSECT AND MITE PESTS OF DECIDUOUS FRUITS AND THEIR CONTROL

D. ASQUITH, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01650)

OBJECTIVE: The evaluation of insecticides and acaricides to find new chemicals to substitute in spray schedules for chemicals to which pests have become resistant; select chemicals suitable for integrated control programs; and select chemicals which will have low potential hazard to the public. The selection of beneficial organisms for their potential adaptability to integrated fruit pest control programs.

APPROACH: Pesticides will be evaluated for effectiveness against the pest complex; phytotoxicity to fruit and fruit trees; effect on beneficial organisms; residual toxicity; hazard to public. Beneficial organisms will be studied in the laboratory and field and selections made for those to be used in integrated control programs. Some species will be subjected to residues of certain pesticides to select strains resistant to pesticides, and these used in the development of an integrated control program.

PROGRESS: Twenty insecticidal treatments were tested for effectiveness on the codling moth, the red-banded leaf roller, apple aphid, European red mite, and two-spotted spider mite. The suitability of some insecticides for inclusion in a system of integrated biological and chemical control of mites in apple orchards was evaluated. Twenty- five acaricidal treatments were tested to determine their effectiveness against the European red mite, the two-spotted spider mite, and certain predatory mites. In addition, some newer insecticides and acaricides were tested in 6X concentrate sprays for integrated chemical and biological control programs. Both Gardona and Imidan showed promise as insecticides in this type of program. Gardona, however, caused serious cracking of Stayman apples and serious russeting of other varieties. Populations of Stethorus punctum survived standard dosage 6X concentrate sprays of Omite WP 30 and Acaralate 2EC, and one-half standard dosage 6X sprays of Fundal SP. S. punctum also survived standard dosage 6X sprays of older acaricides, Kelthane and Morestan.

4.0982, WEED CONTROL IN AGRONOMIC CROPS

S.M. RALEIGH, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01346A)

Objective: Determine most satisfactory methods, materials and techniques for the control or eradication of weeds and other undesirable plant growth. Determine tolerance of various economic plants to ascertain weed and brush control chemicals. Determine the reciprocal relationships of various weed and brush control chemicals and soil microorganisms.

Approach: Promising new and the best commercial herbicides now in use are tested, when practical, for controlling weeds in small grain, forage crops, pasture and inter-tilled crops such as corn and potatoes. Applications are also made on perennial weeds before crops are planted. The chemicals are generally applied at 3 rates per acre or are log sprayed. The effect of the chemical on weed control and on the crop are recorded. The residual effect of chemical is studied in the field on succeeding crop or in the greenhouse. When pre planting treatments are applied for weed control, the interval necessary for eliminating crop injury is observed.

Progress: Monsanto 50144 has been the outstanding preemergence herbicide for annual grass control, under Pennsylvania conditions for the last three years. It is poor on some broadleaf weeds such as Mustard and Common Ragweed. It works exceptionally well in combination with atrazine which is excellent for most annual broadleaf weeds but weak on fall panicum crabgrass and sometimes giant foxtail. Atrazine at 2 lbs. plus oil with wetting agent at 2 gallons per acre or atrazine plus 8 ounces of wetting agent per acre is effective when applied to foxtail or barnyardgrass when the grass is in the 2-4 leaf stage. This treatment is not as desirable as atrazine used in preemergence.

Quackgrass is more readily controlled with atrazine applied pre plowing if the weather is cool and there is considerable rainfall, while Amitrol-T is most effective when the weather is warm and plenty of sunshine.

SUPPORTED BY U.S. Dept. of Agriculture

4.0983, PESTICIDE RESIDUES IN OR ON RAW AGRICULTURAL COMMODITIES

T.W. KERR, Univ. of Rhode Island, Agricultural Experiment Sta., *Kingston, Rhode Island* 02881 (RI00609)

OBJECTIVE: Investigate residues resulting from the use of pesticides and plant growth regulators applied to plants and animals. Develop and standardize sampling and analytical methods for the determination of pesticide residues in or on agricultural commodities.

APPROACH: Pesticide residues will be investigated on forage, animal products, fruits and vegetables. Detailed studies of sampling procedures for the crops will be investigated.

PROGRESS: Potatoes sprayed 4 to 5 times during the 1969 season with 8-16 ounces per acre of the insecticide carbofuran showed less than 0.05 ppm residue at the lesser rate 0, 1, 3, 7, 14, 21 and 28 days after application. Sixteen ounces per acre showed from 0.05 ppm to 0.10 ppm residue 1, 3, 7 and 14 days after application but less than 0.05 ppm thereafter. Both treatments showed less than 0.05 ppm at harvest 53 days after the last application of carbofuran. Potatoes treated in 1968 with 2 and 3 pounds of the herbicide chlorbromuron per acre showed less than 0.03 ppm of residue when analyzed both as washed, frozen samples and unwashed, fresh samples in May 1969.

SUPPORTED BY U.S. Dept. of Agriculture

4.0984, ANALYTICAL SERVICES

O.E. OLSON, South Dakota State University, Agricultural Experiment Sta., *Brookings, South Dakota* 57006 (SD00407)

OBJECTIVE: Provide analytical services to members of the Experiment Station Staff who lack adequate laboratory facilities, with particular attention to certain special types of analysis. Provide chen ical diagnostic services for Veterinary Science. Provide limited analytical service for farmers, ranchers, and other residents or agencies of the state.

APPROACH: Analyses are conducted in accordance with the objectives when there is sufficient need for them. Except in the case of farmers and ranchers, need must be established by those requesting the analyses. In the case of farmers and ranchers, analyses are made whenever, in the opinion of the laboratory the results will be worthwhile. Charges are made for work done for all but members of the Experiment Station staff.

PROGRESS: Station Biochemistry does work for residents of the state to assist them in planning their livestock feeding programs, to assist in the diagnosis of livestock diseases, and to solve other household or farm problems. In addition, many Experiment Station research workers in other departments use the analytical services on a variety of projects. Industry and governmental agencies and workers from other Experiment Stations also use these services on occasion. A summary of analyses made during 1968 is as follows: Moisture determinations 914; Ether extract determinations 389; Protein determinations 1083; Crude fiber determinations 389; Ash determinations 389; Chromic oxide determinations 284; Carotene determinations 81; Salt determinations 16; Mineral analysis on feeds 117; Blood analyses 33; Selenium determinations 193; Special water analysis 26; Nitrate determinations 203; Other poison analyses 127; Insecticide analyses 49; Egg pigmentation analyses 112; Miscellaneous 76. Total: 4481.

SUPPORTED BY South Dakota State Government

4.0985, INSECTICIDAL RESIDUES

R.J. WALSTROM, South Dakota State University, Agricultural Experiment Sta., *Brookings, South Dakota* 57006 (SD00374)

OBJECTIVE: Determine the fundamental physical, biochemical, and biological factors influencing occurrence, magnitude, interaction, and persistence of insecticidal chemical residues in soils and raw agricultural commodities. Identify and evaluate fundamental factors influencing the magnitude and mechanism of air and water pollution by insecticidal chemical residues. Develop basic studies related to the metabolism and detoxication of insecticidal chemical residues in animals, plants, soils and water. Identify and evaluate the effects of residues of insecticidal chemicals on ecosystems with special emphasis on fish and wildlife. Explore the reciprocal influences of residues of insecticidal chemicals on soil microflora, microfauna, and non-insect fauna. Seek methods of removing or reducing residues of insecticidal chemicals from the environment. Develop and improve analytical techniques essential to the pursuit of this research.

APPROACH: Apply insecticides to alfalfa in a dosage range to include the most satisfactory control under northern great plains conditions. Cut samples of forage at intervals following treatment. Samples to be handled as fresh-cut (to simulate pasture and silage) and as field-dried (to simulate hay). Samples to be analyzed for residues on a qualitative and quantitative basis. Samples will be analyzed by the use of gas chromatography and thin-layer chromatography.

PROGRESS: Studied chlorinated hydrocarbon and organophosphorus insecticides in alfalfa and surface soils. Residues of DDT, dieldrin, methoxychlor, and toxaphene detected in treated foliage and soil 52 days after application. Residues of malathion and diazinon dissipated in less than this period after application. No residues of any of the tested insecticides detected on fresh-cut new growth sampled on June 7 the year after application. Data on rate of uptake, translocation, expiration, and metabolism of diazinon in alfalfa obtained utilizing non-radioactive, C ring labelled or C ethyl labeled diazinon. Absorption was rapid with detectable quantities of diazinon appearing in the plant within 24 hours after soil treatment. Loss of diazinon from the soil was rapid with an average of 15% remaining 15 days after application. No radioactive CO(2) detected as a metabolite of C diazinon treatments. Diazinon was expired by alfalfa plants after being absorbed into the plant.

SUPPORTED BY U.S. Dept. of Agriculture

4.0986, CHARACTERISTICS AND POLLUTIONAL PROBLEMS OF PESTICIDE MANUFACTURING WASTES

P.R. ATKINS, Univ. of Texas, School of Engineering, *Austin, Texas* 78712

Project Objectives and Description of Work: Pesticide usage in many portions of the world is increasing at an accelerated rate. The production of the chemicals required to satisfy these demands often results in wastes which may be harmful to aquatic organisms, plants, animals, and man. Information concerning these waste streams, is scattered, confused, and often unavailable. The purpose of this proposed study is to investigate the quantity and quality of pesticide manufacturing waste streams and to evaluate the methods presently being employed to treat and dispose of the pollutants. The study area involved will be limited to the continental United States and Canada.

The project will include: 1. A comprehensive review of the literature dealing with historical, present and projected pesticide usage, manufacture, and waste water treatment. 2. A survey of a number of major manufacturing plants, including site visits and personal interviews where possible. The production process used, the wastes produced, and the treatment and disposal methods utilized will be investigated. 3. A completion and evaluation of the information obtained from the literature, site visits, industry reports, agency reports, research projects, and other sources. 4. The development of recommendations on the type of research needed in this area. 5. The development of a complete and comprehensive bibliography on pesticide wastes and waste treatment.

This project was to begin July 1, 1970 and terminate June 30, 1971.

4.0987, THE EFFECT OF PESTICIDES ON AN ECOSYSTEM

H.G. APPLEGATE, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (TEX04001)

OBJECTIVE: At Presidio, Texas, to follow changes in pesticide concentration in soil, water, bird, reptile, and animal tissue,

human urine and vegetation for a 3 year period; determine changes in water and soil biota as functions of the physical and chemical environments; compare species and populations of native organisms living in an area heavily treated with pesticides with those from a similar area not treated with pesticides.

APPROACH: Samples of various organisms, soil, water and air will be extracted and studied for pesticides. The pesticide concentrations will be studied in three dimensional space and correlated with time and site of application.

PROGRESS: Previous work indicated that soil temperature, soil alkalinaty and ultra-violet radiation were instrumental in breaking down DDT at Presidio. Laboratory data indicate that of the three factors ultra-violet radiation is the most important and soil alkalinaty the least important. The high incidence of male C tesselatus has been related to high DDT concentrations. It appears as though DDT biochemically resembles steriod hormones. Methyl parathion appears to be immobile once it reaches the brain of mammals. Preliminary data indicates a linkage between methyl parathion concentrations in the brain and motor behavior.

SUPPORTED BY Texas State Government - Austin

4.0988, PESTICIDE RESIDUES IN AGRICULTURAL COMMODITIES AND ENVIRONMENTS

F.W. PLAPP, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (TEX02731)

OBJECTIVE: Perform fundamental methodology studies concerned with state residue programs. Participate in referee sample exchange involving regional problems. Conduct fundamental studies on the fate of pesticides in plants, animals and soils. Determine rates of disappearance of pesticide residues from agricultural commodities and environments.

APPROACH: Methods appropriate for the determination of residues under Texas conditions will be developed. This involves work on sampling, extraction, and clean up to selected research samples prior to analysis. Research will be conducted on the fate of pesticides in insect species of major importance in Texas with particular reference to lepidopterous species attacking cotton. This work will involve assays and comparisions of insect populations from different areas of the state. Persistence of residues of important pesticides in the environment will be measured by appropriate analytical techniques.

PROGRESS: Investigations were undertaken on insecticide resistance, particularly resistance to the organophosphates methyl parathion and Azodrin, in Heliothis virescens as compared with the more susceptible H. Zea. C experiments showed a greater conversion of toxicants to watersolubles in virescens and that the reaction was of the NADPH-dependent type. Attempts to block the reaction by synergists have been unsuccessful, but substitute organophosphate insecticides, not detoxified by NADPH-dependent reactions have been found which block resistance. In house flies, induction of detoxifying enzymes as a consequence of exposure of insects to chlorinated insecticides is being investigated. Other work involves measurement of pesticide residues in water and animals of the Brazos River system.

SUPPORTED BY U.S. Dept. of Agriculture

4.0989, AGRICULTURAL CHEMICAL RESIDUES IN PLANT AND ANIMAL PRODUCTS

E.L. WISMAN, Virginia Polytechnic Institute, Agricultural Experiment Sta., *Blacksburg, Virginia* 24061 (VA-0626105)

Objective: Determination of residues and their metabolites in agricultural commodities and in their environment.

Approach: The effects of certain chemicals on market quality factors (egg shell thickness, albumin quality as measured by Haugh units, yolk color), and chemical residues in market eggs when the chemicals are fed in the diet in graded levels, will be evaluated. The chemicals to be tested are planned to include DDT, Sevin, Malathion, Diazinon, Heptachlor, Chlordane and ethylene dibromide. Test chemicals drugs that are used directly in poultry rations or in the environment.

Progress: This project is being reassigned from S-22 to S-73. Continuous feeding of Sevin up to 50 ppm fro 28 days resulted in egg residues. Up to 1000 ppm level caused slight egg residues but they disappeared upon immediate withdrawal of the pesticide from the feed. Continuous feeding of Diazinon up to 50 ppm for 28 days resluted in no egg residue. Beyond this level, feed consumption ceased indicating a palatibility factor. Following withdrawal of Heptachlor after 49 days of continuous feeding at 1.0 ppm, egg residues were detectable until 31 weeks later. Supracide (GS 13005), an organophosphate, left no residue in egg yolk when fed to hens at a 10 ppm for 30 days. At 100 ppm, small residue appeared but quickly disappeared once the dietary source was withdrawn. At 500 ppm, feed consumption and egg production were reduced. The level of any environmental contamination would never be expected to exceed 1 ppm.

SUPPORTED BY U.S. Dept. of Agriculture

4.0990, AGRICULTURAL CHEMICAL RESIDUES IN PLANT AND ANIMAL PRODUCTS

R.W. YOUNG, Virginia Polytechnic Institute, Agricultural Experiment Sta., *Blacksburg, Virginia* 24061 (VA-0626103)

Objective: Development, adaptation and standardization of chemical, instrumental and biological methods of residue analysis. Investigate behavior of chemicals as related to residues in agricultural commodities. Determine residues and their metabolites in agricultural commodities in their environment.

Approach: Persistent data from promising new pesticide introductions and others will be tested on vegetables. The effect of temperature and light intensity on pesticide residues will be studied. Improvements of analytical methods will be made. Collaborative work with the Tennessee Experiment Station and the Virginia Truck Experiment Station will be continued on the study of 5 clean-up procedures for collards with DDT at lower levels of pesticides and the effect of cooking upon pesticide residues.

Progress: Residue studies on the uptake of DDT and dieldrin in peanuts and turnip greens and their persistence in the soil was completed and prepared for publication. A collaborative project with the Florida Laboratory, studying the effects of plant oil (as a contaminant of the sample) on the sensitivity of the detectors and columns, is in progress. The detectors included are electron capture and microcoulometric. Columns with and without prior use are being tested to determine if these factors may effect the stability of the columns injected with oil contaminanted samples. The two columns being used are 10% Dow 200/500 on 50/60 mesh Chromosorb p and 4% SE - 30 plus 60% QF 1 and 80/100 mesh Chromosorb Q. The detectable level of dieldrin (contaminated samples) was depressed on one column and one detector. Further studies are in progress. We have found that the rate of pesticide breakdown is faster in the coastal area of Virginia than in the mountain area. Studies are in progress to improve the Sevin method and to determine the persistence of Sevin in eggs from hens fed the pesticides. The persistence of GS 13005 in hens and feed has been determined, a method developed, and papers submitted for publication. Cooperative projects on the movement of 2-4-D and picloram in trees are in progress with the plant pathology department. Further persistence studies on residues in apple orchard soils are in progress in cooperation with horticulture.

SUPPORTED BY U.S. Dept. of Agriculture

4.0991, NUTRITIONAL INTERACTION BETWEEN UREA AND APPLE POMACE RELATED TO REPRODUCTIVE FAILURE

K.P. BOVARD, U.S. Dept. of Agriculture, Animal Science Research Div., *Front Royal, Virginia* 22630 (0330055221349)

OBJECTIVE: Determine if a biological interaction occurs between urea and the pesticide residues or ether extract portion of apple pomace within pregnant beef cows to cause abortions and/or malformed fetuses.

APPROACH: At the Beef Cattle Research Station, Front Royal, Virginia, pregnant beef cows will be used in a factorially designed experiment to study the effects of pesticide residues, urea and oil when added to a low protein diet other than apple pomace. Primary measurements to be taken concern survival or health of the calves produced when cows are exposed to these materials. Physiological aspects of these treatments will be considered under CRIS Unit 055-1.

PROGRESS: Forty-eight pregnant cows were placed in 8 lots and fed diets to determine the influence of starch vs. soybean oil, urea vs. cottonseed meal and pesticides vs. no pesticides on reproductive performance. Results indicate that cows fed urea required longer eating times, had lighter calves (6 lb. average) at birth and lost considerably more weight during the study than did cows fed cottonseed meal. Adding pesticides to the urea treatment seemed to intensify these results. No stillborn or abnormal calves were observed in this study.

SUPPORTED BY U.S. Dept. of Agriculture

4.0992, RESIDUES OF SELECTED PESTICIDES IN PLANTS, ANIMALS, AND THE PHYSICAL ENVIRONMENT
K. GROVES, Washington State University, Agricultural Experiment Sta., *Pullman, Washington* 99163 (WNP01634)

OBJECTIVE: The metabolism of pesticide residues by plants and microorganisms as factors in modifying residue levels in food chains and in the environment.

APPROACH: Soils will be incubated with chloro-phenyl type pesticides, including DDT for periods of time to enrich them in microorganisms capable of utilizing them as substrates. Carbon-14 labeled pesticides will be added, and labeled metabolic products separated by thin-layer chromatography and scanning. Chlorine-36 labeled dichloran will be used to investigate chlorine carbon bond metabolism.

PROGRESS: DCNA (Botran (R)) disappearance from onion field soil, and the evolution of C-14 labeled carbon dioxide from the soil after application of labeled DCNA suggest microbiological destruction. No labeled carbon dioxide evolved from steam or chemically sterilized soil. Destructive activity of the soil increased by incubation with applied DCNA. Three of the six labeled carbon atoms of DCNA were evolved. Combustion of evolved gases gave same ratio. Non-volatile portion not identified. Cultures of two segregated unidentified organisms decomposed DCNA. Persistence of DCNA may be increased when applied to soil previously treated with chloropicrin or a mixture of methyl bromide and chloropicrin. Residual bromine, as determined by neutron activation analysis, was higher in soils treated with methyl bromide-chloropicrin mixture than with methyl bromide alone even though the latter was applied at higher rates. Further investigation is planned. Sodium arsenite field studies continued as described in 1967. No evidence of phytotoxicity to potatoes after four annual applications. Analyses of potatoes, soil, and irrigation run-off water are pending.

SUPPORTED BY U.S. Dept. of Agriculture

4.0993, NORTHWEST TREE FRUIT INSECTS
H.R. MOFFITT, U.S. Dept. of Agriculture, Entomology Research Division, *Wenatchee, Washington* 98801 (00ENTB0802500700)

OBJECTIVE: Development of chemical, biological, and other non- chemical methods for control of insect and mite pests that attact deciduous fruits.

APPROACH: Screen and evaluate miticides and biologically active chemicals that may affect reproduction or metabolism in mite and insect pests. Evaluate and determine the nature of resistance to insecticides in codling moth, pear psylla, and McDaniel mite. Develop strains of natural enemies of insect pests of deciduous fruits better able to resist insecticides. Develop integrated control programs that will prevent economic injury by the pests through at least partial employment of biological methods and greatly reduce or minimize contamination by persistent residue and other problems associated with insecticide usage.

PROGRESS: A study of mite populations in an orchard treated with insecticides for codling moth control and in one in which sterile codling moth males were released for codling moth control showed that the mite populations peaked about 3 weeks earlier in the release orchard than in the sprayed orchard. Data from sampling mite populations indicated that P. ulmi and A. schlectendali were present in low numbers, rarely averaging over one mite per leaf. Z. mali was not encountered in any of the samples. T. mcdanieli and T occidentalis were the only mites present in appreciable numbers which reached a maximum number of about 67 adults per leaf. Economic damage was not determined. Codling moths irradiated as adults with 25 or 40 krad were more tolerant to azinphosmethyl, carbaryl, and p.p.'DDT than untreated moths. Females were 1.4 to 1.6 times more tolerant and males were up to 1.5 times more tolerant to the insecticides than their untreated counterparts.

SUPPORTED BY U.S. Dept. of Agriculture

4.0994, PESTICIDE RESIDUE INVESTIGATIONS, YAKIMA
L.M. MCDONOUGH, U.S. Dept. of Agriculture, Entomology Research Division, *Yakima, Washington* 98902 (00ENTM0304500800)

OBJECTIVE: Determine the amount, persistence, and fate of residues of new insect control chemicals and their metabolites or breakdown products in agricultural crops of the Pacific Northwest, soils, animal products, and wildlife.

APPROACH: Obtain information through analysis on rate of deposition, distribution, persistence, and fate in plants, animals including wildlife, and soils of residues of chemicals applied for insect control and of their metabolites and breakdown products. Analyze pesticide formulations to be used in experiments on control of insects attacking fruits and vegetables.

PROGRESS: During the past year 526 analyses were completed. The analyzed samples included alfalfa, mint hay, oranges, lemons, soil, potatoes, tomatoes, tomato foliage, lettuce, and cucumbers. The pesticides determined included aldicarb and toxic metabolites, parathion and paraoxon, DDT and metabolites, malathion, and carbofuran and toxic metabolites.

SUPPORTED BY U.S. Dept. of Agriculture

4.0995, EFFECTS OF BIOCIDES ON PROPERTIES OF NURSERY STOCK
J.R. BOYLE, Univ. of Wisconsin, Agricultural Experiment Sta., *Madison, Wisconsin* (WIS01438)

OBJECTIVE: Evaluation of effects of eradicant treatments on biological and chemical aspects of soil fertility and the development of nursery stock.

APPROACH: Chemical and microbiological analyses of soils treated with various biocides, particularly Mylone, Dacthal, and Vapam. Morpho- anatomical and physiological analyses of nursery stock produced in the presence of different agricultural chemicals. Bioassays. Determination of degradation products and residual accumulation of eradicants. Determination of mycorrhiza formation and structure compared to untreated and naturally reproduced seedlings.

PROGRESS: Prolonged use of biocidic fumigants of methyl bromide type has resulted in suppression of symbiotic fungi, nodule bacteria, and extra-matrical chelating organisms. The subsequent disruption of the symbiotrophy of tree seedlings in some instances rendered planting stock of unsatisfactory growth potential. Restoration of the productive capacity of biocide-treated soils was achieved by the use of certain types of forest humus incorporated with the soil or applied in the form of fertilizer-reinforced suspensions. The costly collection of humus debris dictates introduction of less expensive carriers of humate suspensions harboring beneficial microorganisms, viz., fermented sawdust, tree bark, and sedge or wood peat. The amelioration requires certain adjustment of both composted carriers and inoculating humate suspensions. Promising results were also obtained by foliar sprays of nursery stock with ammonium phosphate and by periodic applications of weak solutions of allyl alcohol; the latter encourages invasion of Trichoderma spp., fungi augmenting availability of phosphorus.

4.0996, SWEET CLOVER TOXICITY AND CHEMICAL AND PHYSIOLOGICAL STUDIES ON DICUMAROL AND WARFARIN
K.P. LINK, Univ. of Wisconsin, Agricultural Experiment Sta., *Madison, Wisconsin* (WIS00850)

Warfarin and its metabolites are excreted by the rat in urine (2/3 of the dose) and feces (1/3 of the dose). For metabolic fate

studies in rats, 1 mg i.j. doses of 4- C warfarin sodium were administered weekly. Urine and feces were collected and frozen daily during the seven days following dosing. All of the urinary radioactivity was extracted and identified, using ether extraction, chromatographic (paper and thin-layer) and inverse isotope dilution techniques. The urinary metabolites were unchanged warfarin (6.6% of urinary radioactivity) several hydroxylated warfarin derivatives: 7- hydroxywarfarin (35%), 4- hydroxywarfarin (21%), 6-hydroxywarfarin (15.4%), 8-hydroxywarfarin (8.9%), a glucuronide of 7-hydroxywarfarin (6%) and an intramolecular condensation product: 2,3-dihydro-2-methyl-4- phenyl-5-oxo-gamma-pyrano (3,2-C) (1) benzo pyran (6.6%). Chromatographic data indicated the presence of these metabolites in feces but in different relative amounts than in urine.

4.0997, EFFECTS OF PESTICIDES USED IN DAIRY INDUSTRY

D.D. DEANE, Univ. of Wyoming, Agricultural Experiment Sta., *Laramie, Wyoming* 82071 (WYO00930)

Objective: Determine the minimum concentration of various insecticides required to affect the growth of microorganisms used in the manufacture of dairy products. Determine the effect of such toxic levels of insecticide upon the growth characteristics of pure cultures of the organisms studied.

Approach: The effect of various levels of insecticide upon the growth of pure cultures of representative strains of the microorganisms used in the manufacture of dairy products will be studied. Growth characteristics including rate of growth, total population, rate of acid production and cell morphology will be studied. The insecticides studied will be representative of those used by the dairy industry.

Progress: Lactic cultures showed a varied growth response to presence of insecticides depending upon insecticide added, concentration, number of culture transfer and culture strain. Neither malathion nor trichlorfon at 100 ppm affected acid production by Streptococcus lactis, Streptococcus cremoris, Streptococcus diacetilactis or Lactobacillus bulgarious. Greatest effect was on morphology. L. casei (Wisc.) formed longer chains of cells after 15 to 20 transfers in milk to which 100 ppm malathion had been added prior to sterilization. A lesser effect was noted with 500 ppm trichlorfon. Morphology appeared normal following subsequent transfers in insecticide-free milk. Five other strains of L. casei failed to exhibit as consistent a change in morphology. Two of seven strains of S. thermophilus showed variation in cell size after several transfers in milk to which 100 ppm malathion or 500 ppm trichlorfon had been added prior to sterilization. Adding the insecticide as an alcoholic solution to the milk following sterilization did not increase effect of the pesticides. Carbohydrate fermentation patterns were not affected by culturing the organisms in presence of the two insecticides used. The effect noted following growth of the lactic organism in presence of these two insecticides was morphological. Degree of change produced depended upon species and strain of organism tested and the level of insecticides required was above that previously found in milk.

4.0998, UPTAKE OF MERCURY BY PLANTS AND ITS DISTRIBUTION IN LIVING ORGANISMS IN AN ENVIRONMENT WITH INCREASED CONCENTRATION OF THIS ELEMENT

L. KOSTA, Inst. Jozef Stefan Nuklearne, *Ljubljana, Yugoslavia*

The studies proceedings on the uptake, distribution and body burdens of plants, animals and human subjects will be continued, with increased stress on the latter.

The intake, distribution and excretion of mercury in certain subjects will be measured, and methods for the identification of some metabolites by TLC, GLC and disc electrophoresis developed. Special attention will be paid to possible transformation processes of inorganic to organomercury compounds in vivo for some organisms.

Results will be compared for the Idrija area with some obtained from an area contaminated by organomercurial pesticides and another area with a naturally high soil mercury content but no atmospheric contamination. Experimens will be made with animals (fish and/or rabbits) to investigate whether local Idrija varieties have developed resistance to high mercury levels (e g. by natural selection) compared to animals from uncontaminated areas.

F. ANALYSIS, MONITORING, AND INSTRUMENTATION

Residue Analysis, Long-term Monitoring, Or Pesticide Detection Techniques and Instrumentation.

4.0999, RADIOTRACER STUDIES ON THE MECHANISM OF INSECTICIDAL TOXICITY

J.E. CASIDA, Univ. of California, School of Agriculture, *Berkeley, California* 94720 (AT(04-3)34,0113)

The studies generate information needed on metabolism, photodegradation, biochemistry, fate, and mode of action of important insecticide chemicals to evaluate conditions for their safe and efficient use. They concern 1) degradation and mode of action of pyrethroids, rotenone, ubiquinone, certain esterase inhibitors, synergists, phosphorylation uncouplers, and certain juvenoids, 2) binding sites of rotenone, ubiquinone, and piericidin A in the respiratory chain components, 3) biochemistry of induction of abnormal chicken embryos, 4) biochemical genetics of resistance in house flies, 5) sensitization of photoalteration of insecticide residues, 6) mechanism of oxon formation from organophosphorothionate compounds, 7) degradation and mode of action of new insecticide chemicals, and 8) factors that control the selectivity and persistence of insecticide chemicals. An important aspect of these studies and, frequently, the critical factor is the synthesis of radiolabeled insecticide chemicals, of high stereochemical and radiochemical purities, with high specific activity for use in analytical and characterization studies.

Results: Much is now known about the metabolism and biochemistry behavior of esterase-inhibiting compounds, rotenone, pyrethroids, methylenedioxyphenyl synergists, and certain respiratory uncouplers in mammals and insects, but, except for carbamates, there is a paucity of such data in plants. There is a better understanding of the binding of rotenone, piericidin A, and ubiquinone in submitochondrial particles, of factors involved in resistance and in the biochemical genetics of resistance, of the photoalteration of insecticide chemicals on plants, of the mechanism of oxon formation by organophosphorothionate compounds, and of the metabolism of esterase inhibitors by mixed-function oxidases.

4.1000, SYSTEMS APPROACH TO CONTROLLING PESTICIDE CONTAMINATION OF SAN JOAQUIN VALLEY

W.W. KILGORE, Univ. of California, School of Agriculture, *Davis, California* 95616

The long-term objective of the San Joaquin Valley Project is to develop a body of knowledge to help minimize the environmental contamination attendant upon continued large-scale use of pesticides in this heavily cultivated valley.

The San Joaquin Valley, the southern part of the central valley of California, is ringed on three sides by mountains and is drained by the San Joaquin river and its tributaries to the north, then westward into San Francisco Bay. Within this partially enclosed system lies one-third of California's farmland, including the most extensive area of irrigated land in the U. S. About a fifth of America's table food is grown here, but a part of this high productivity of vegetables and other crop is achieved through the annual application of one-seven of the pesticides used in the U. S.

This grant is for a one-year planning project that will (1) establish a computerized data bank with the detailed information on past and current pesticide use, (2) plan for investigations of the incorporation of these toxic compounds into the biota, and the degradation of these compounds left in the inorganic environment, and (3) begin the simulation modelling of the dispersal and fate of the pesticides.

SUPPORTED BY U.S. National Science Foundation

4.1001, THE CHEMISTRY AND TOXICOLOGY OF AGRICULTURAL CHEMICALS
W.W. KILGORE, Univ. of California, School of Agriculture, *Davis, California* 95616

This is a program project concerned with the chemistry and toxicology of selected agricultural chemicals. The program is broad in scope, encompassing not only a number of specific research projects, but also a program planning and coordination activity. The activities of the Director's Office involve the planning, activation and coordination of research and training projects related to the mission of the Food Protection and Toxicology Center.

All research projects relate to the Chemistry and Toxicology of Agricultural Chemicals. They are categorized under three general headings: 1) Analytical Methods and Instrumentation, 2) Biological Manifestations of Toxicity, and 3) Environmental Fate of Pesticides and their Effects.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.1002, ENVIRONMENTAL DECONTAMINATION, ESPECIALLY FOR FEEDSTUFFS AND ASSOCIATED FOODS
G.F. STEWART, Univ. of California, Agricultural Experiment Sta., *Davis, California* 95616 (CA-D0-ETX-2301-RR)

OBJECTIVE: Environmental decontamination of pesticides in relation to animal feeds and associated human foods, and ecological contamination; basic knowledge for removal or conversion to innocuous products of pesticides by treatment with chemical, physical or combination of both procedures.

APPROACH: Research will be directed toward the pesticides most likely to present problems in the more important feedstuffs and associated foods. Samples will be studied physically to determine possibility of surface or internal contamination. Volatile substances will be detected by gas-liquid and thin-layer chromatography; non- volatile substances may require hydrolysis to release the residue from the polysaccharides, glycols, protein, etc., prior to extraction and cleanup for quantitative analysis. Quantitative analysis will involve separation of parent compounds and their breakdown products. Emphasis will be placed on the search for the quantitation of each major contaminant or breakdown product.

PROGRESS: Green alfalfa, sprayed in the laboratory with large concentrations of DDT 2,2 bis(p-chlorophenyl)-1,1,1-trichloroethane , was air dried in the dark, dried in sunlight, and dried under ultraviolet lamps at 2537 A to observe the effects of these treatments on the pesticide stability. Gas-liquid chromatography (GLC) and thin- layer chromatography (TLC) procedures were employed routinely, either separately or in combination. No changes occurred to the DDT in the dark treatment, excpet 49% of the original residue was lost by the eighth day of the drying process and no further loss was observed during the 11th day of the experiment. On the fourth day of the ultraviolet lamp treatment DDD 2,2-bis(p-chlorophenyl)-1-1-dichloroethane was formed from the DDT, but no change occurred with the DDE 2,2,-bis)p- cholorophenyl)-1,1-dichloroethylene present, and a maximum of 67% of the total original residue was lost by the sixth day during the eleven day drying process. On the sixth day of the sunlight treatment, DDD was found from the DDT, but no change occurred with the DDE present, and a maximum of 72% of the total original residue was lost by the eleventh day of the drying porcess.

SUPPORTED BY U.S. Dept. of Agriculture

4.1003, RESIDUES AND BREAKDOWN PRODUCTS OF CHEMICAL FUNGICIDES IN PECAN NUTS
A.A. PIRINGER, Stanford Research Institute, *Menlo Park, California* 94025 (0860-05-19(C))

OBJECTIVE: Determine the extent to which residues of the fungicides, duter, dodine, and zineb, enter the pecan nut as a result of applying these compounds for scab control, and determine whether residues of these chemicals persist in orchard-floor vegetation.

APPROACH: Initially, methods will be developed to detect the fungicides and their breakdown products in pecan nuts and in the vegetation under treated trees. The analytical methods used will range from classical chemical methods for extraction of the tin and zinc of duter and zineb, respectively, to modern methods of selective organic analyses for the organic compounds and fragments of the fungicides. After suitable methods of analysis have been developed, the USDA will provide the Stanford Research Institute with appropriate samples of pecan nuts and orchard-floor plants from trees and orchards having known fungicide application histories. The developed analytical methods will be used to determine the amounts and distribution of dodine, duter, and zineb and their breakdown products in the pecan kernels and the orchard- floor plants.

PROGRESS: Pecan kernel and cover crop samples with known fungicide spray histories are being analyzed. Methods of analysis for residues of dodine and duter in pecan kernels have been developed. The method for dodine is based on a procedure described by Steller, et al. (J.Agr.Food Chem.,8,1960). Dodine is extracted from the sample and the extract is purified. The purified extract is treated with bromocresol purple which forms a complex with dodine. The concentration of dodine is determined by measuring the concentration of bromocresol purple that is liberated from the complex. The optical absorbance is measured at 590 millimicrons. A new method of analysis for residues of duter based on polarography was developed in this study. The duter residue is extracted into petroleum ether, then into dimethyl sulfoxide and finally into methylene chloride. The methylene chloride is evaporated off and the residue is oxidized with sulfuric, nitric and perchloric acids. The resulting inorganic tin is measured with single-sweep polarograph.

SUPPORTED BY U.S. Dept. of Agriculture

4.1004, ANALYTICAL METHODS FOR INSECTICIDES AND ACARICIDES AS RESIDUE METHODS AND AS COMPOSITION METHODS
F.A. GUNTHER, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-R0-SSE-1576)

OBJECTIVE: Develop and apply microanalytical methods for residues of pesticide chemicals persisting in foodstuffs.

APPROACH: Residue evaluation of the new compounds dimethoate and 'OW-9' on a variety of crops, and the occurrence of carcinogenic polynuclear aromatic compounds in citrus tissues from both preharvest and postharvest applications of petroleum derived substances in the production and marketing of citrus fruits.

PROGRESS: Methods of analysis for residues of Plictran, Omite, phosalone, Torak, and Temik were checked for use on citrus fruits, modified where necessary and used for residue persistence studies for these insecticides and acaricides in and on oranges and lemons. Substantial progress has been made on an improved procedure for determining residues of Plictran. Procedures for determining residues of the insecticide Dursban in aquatic life and habitat were developed to aid research on the use of this compound as a mosquito larvacide. The methods developed were used to analyze samples of vegetation, mud, water, fish, ducks, crustaceae and insects. A method for determining residues of Ciodrin insecticide in animal tissues and milk, utilizing oscillographic polarography, was developed and published. During this investigation, an excellant gas chromatographic procedure was also found that may prove useful when polarographic equipment is not available. Research is under way to develop a more rapid and dependable procedure for determining residues of organochlorine pesticides in meat, utilizing the microcoulometric gas chromatograph as the detection method. The need for improved methods for this purpose is particularly critical because of the general occurrence of organochlorine residues in meat and the resulting tremendous analytical load for regulatory agencies throughout the world.

4. PESTICIDES

SUPPORTED BY California State Government - Sacramento

4.1005, AUTOMATED ANALYSIS OF PESTICIDE RESIDUES

F.A. GUNTHER, Univ. of California, School of Agriculture, *Riverside, California* 92502

Automated pesticide residue determinative methods suitable for food, soil, and water monitoring purposes have been developed for pesticides that contain Cl, P, S, and for those that are ChE inhibitors. Automated general and specific cleanup methods are under development, and some specific residue methods have been developed in conjunction with the thus far successful cleanup unit operations. Automated methods for the extraction of soil and water samples are under development.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.1006, PESTICIDES AND WILDLIFE

M.S. MULLA, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-R0-SSE-2131)

OBJECTIVE: Study the relationship of insecticides to wildlife species. Develop specific public health insect control measures in wildlife habitats, with the hope to eliminate or diminish hazards to non- target species.

APPROACH: The productivity, food chain relationships and biological characteristics of predominant components of the ecosystem will be investigated. Degradation and detoxification avenues and mechanisms in a variety of habitats and organisms will be elucidated. Residues of insecticides in water, surface and sub-soil strata, aquatic vegetation and non-target organisms, by means of gas chromatography. Colorimetric procedures and other appropriate analytical methods will be studied. The biological and toxicological effects of insecticidal treatments influencing animal populations in the treated area will be investigated will be investigated.

PROGRESS: Residue analytical methods were developed and applied in a field project for Dursban that could accumulate in mud, water, aquatic plants, aquatic organisms, fish, ducks, and insects. Analytical methods were developed for reproductively determining. The true and apparent solubilities of organochlorine pesticides in very pure water and in 'soil water.' The utility of the forced volatilization technique for the cleanup of pesticide or residue-containing extractives was precisely evaluated for several organochlorine insecticides. Biological effects of Dursban an organophosphate larvicide was studied in a freshwater ecosystem. This material was highly toxic to Cladocera, less toxic to Copepods, but not toxic to rotifers.

SUPPORTED BY California State Government - Sacramento

4.1007, PHYSIOLOGY OF CITRUS FRUIT ABSCISSION

B.J. ROGERS, Univ. of California, U.S.D.A. Crops Research Div., *Riverside, California* 92507 (0840-04-16)

OBJECTIVE: Determine the physiological basis of abscission of citrus fruit and search for effective abscission chemicals for commercial use on fruit harvested for fresh fruit purposes.

APPROACH: Conduct basic studies on the nature of the biochemical changes in the abscission zone of citrus fruit following treatment with ethylene-producing chemicals and various growth regulators. Develop suitable laboratory test methods for potential abscission-inducing chemicals. Conduct field trials with the most promising chemicals to determine their commercial feasibility. Determine chemical residues on citrus following chemical treatment and determine the breakdown products of abscission chemicals.

PROGRESS: The effectiveness of cycloheximide as an abscission agent was studied for Valencia and navel oranges for inland (i.e., Riverside) conditions and for lemons, grapefruit, and Valencia oranges under desert conditions. Grapefruit appeared to be most sensitive. Abscission is controlled by tree growth stage, temperature, and humidity. Under inland winter conditions it is extremely difficult to induce abscission of navel oranges. Sensitivity of citrus fruit to ethylene was approached by studying the enzymology of abscisson of fruit on the tree and in the laboratory. Pectinase formation was selected for study, since on a priori grounds the enzyme appears necessary and sufficient for abscission. A method for extracting the enzyme from woody tissue was worked out. Increased synthesis of the enzyme is dependent on temperature and ethylene, and can be halted by appropriate inhibitors. Synthesis of the new enzyme is localized with respect to occurrence in the abscission zone. Preliminary results indicate that the formed enzyme is extremely labile and requires the continued presence of ethylene for formation. Divalent ions also have an effect.

SUPPORTED BY U.S. Dept. of Agriculture

4.1008, RADIOACTIVITY, PESTICIDE RESIDUES CONTENTS AND CONSTITUTION OF MILKS OF ARCTIC AND SUB-ARCTIC SPECIES

B.E. BAKER, Mcgill University, *Montreal, Quebec, Canada* (AT(30-1))

The aim of this investigation is to provide information on (a) the levels of Sr-90, Cs-137, and pesticide residues in the milks of Arctic and Sub-Arctic species and (b) the constitution of these milks. Attempts will be made to correlate the radioactivities of the milks with the eating habits and environmental conditions of the animals or humans. From the detailed study of the constitution of the milks it is hoped that the function of certain milk components can be explained. The methods and procedures that will be used will be those which are already in use in the study of bovine milk. Milk has been collected from the following mammals in the Northwest Territories and Yukon (Canada), Alaska (U.S.A.) and Lapland (Finland) - polar bears, grizzly bears, wild sheep and goats, wolves, huskies, muskox, hare, caribou, reindeer, whales, seals, moose and humans. Samples of milk are being sent to us continuously by scientists from the following institutions: - Wildlife Service, Dept. of Indian Affairs and Northern Development, Canada (Yukon and Northwest Territories); Dept. of Fish and Game, State of Alaska; Dept. of Health, Education and Welfare, Public Health Service, Alaska; University of Alaska; University of Helsinki, Finland; and Hankkija Company Helsinki, Finland.

SUPPORTED BY U.S. Atomic Energy Commission

4.1009, DETERMINATION OF PESTICIDES IN BIOLOGICAL AND ENVIRONMENTAL SPECIMENS

W.H. ROBINSON, U.S. Dept. of the Interior, Bureau of Sport Fish. & Wlife., *Denver, Colorado* 80225

Objectives: To supply analytical services to all Pesticide Wildlife study projects, Division of Wildlife Services operational personnel, other federal, state and local governmental agencies requiring limited amounts of analytical services.

Procedures: The major portion of the work performed in this segment of the project involves: (1) paper, thin-layer, column and gas chromatography, (2) conventional 'wet' methods, (3) standard bioassay procedures, (4) infrared, ultraviolet, emission and atomic absorption spectroscopy, (5) Colorimetric and other methods as required.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.1010, INDUCED PHOTOLYSIS OF ORGANIC HALIDES PATHWAYS FOR PHOTODECOMPOSITION OF DDT

L.L. MILLER, Colorado State University, Agricultural Experiment Sta., *Fort Collins, Colorado* 80521 (COL00048)

OBJECTIVE: The feasibility of inducing the photochemical decomposition of organic halides will be investigated. The induced photochemical decomposition of DDT will receive special attention.

APPROACH: Photolyses at wavelengths 0 3000 A will be undertaken with a variety of representative donors in a brief screening process to discover what sort of structural characteristics are necessary for induced decomposition. A more intensive study of those donors which are most effective will involve isolation and characterization of the photoproducts and elucidation of the reaction mechanism. The products and pathways of induced DDT photolysis will also be investigated.

PROGRESS: The induced photolysis of DDT has been investigated. Irradiation of DDT in cyclohexane solution at 3100 A gives no reaction. Addition of suitable inducers, however, dehalogenates DDT forming up to 2 equivalents of HCl/equivalent of DDT initially present. Products identified are DDD, DDCO and DDE. Two requirements for the inducer are 1) Adsorption of solar light, e. g. 3000 A; 2) A low ionization potential.

SUPPORTED BY Colorado State Government

4.1011, COLLABORATIVE STUDIES OF ANALYTICAL METHODS

M. FUZESI, Conn. Agric. Expt. Station, *New Haven, Connecticut* 06504 (CONH00108)

OBJECTIVE: Study analytical methods in the areas of feeds, fertilizers, foods and pesticides and to check the performance of this laboratory as compared with other laboratories doing similar works.

APPROACH: Collaborative samples furnished by the A.O.A.C. and other organizations are analyzed. The results are compared with results obtained by other laboratories.

PROGRESS: Study of published methods and devising of new methods for the analysis of foods, drugs, cosmetics, feeds, fertilizers, pesticides, and plant materials. Messrs. Keirstead, Mueller, Squires, Wickroski and Mrs. Fusezi have served as collaborators in A.O.A.C. and other studies of methods in the feed, fertilizer, food, pesticide and residue areas.

SUPPORTED BY Connecticut State Government

4.1012, CHEMICAL CONTROL OF WEEDS IN NURSERY AND TURF PLANTINGS

I.F. AHRENS, Univ. of Connecticut, Agricultural Experiment Sta., *Storrs, Connecticut* 06268 (CONH00604)

OBJECTIVE: Evaluate single and repeated pre-emergence treatments of nursery plants and turf, determine persistence of herbicides in soil, investigate factors affecting response of nursery plants to herbicides, determine need for cultivation and investigate control of Poa annua, quackgrass and nutgrass in turf and nurseries.

APPROACH: Apply herbicides in single and double dosages on transplanted nursery crops (replicated plots). Determine growth of new plants. Assay soil for persistence of residues. Studies will be made on turf. Determine interactions of rate of fertilization, rate of application and type of herbicide on phytotoxicity to nursery plants. Determine need for cultivation in nurseries treated for weed control. Study life history of Poa annua, and test herbicides on it and on quackgrass and nutgrass in nurseries.

PROGRESS: The effect of dichlobenil on assimilation and transport was studied in peach seedlings. At levels of 1-1/2 ppm or higher in a sand-peat mix, dichlobenil inhibited root and shoot growth. At 12 or 18 days after planting, fixation of C O(2) by peach leaves was depressed by dichlobenil in the root zone. At 32 or 49 days, leaves of dichlobenil- treated plants fixed about as much C O(2) per unit leaf weight as untreated plants. Transport of C - labelled assimilates was depressed by dichlobenil after 12 days but later on slightly greater percentages of labelled assimilates were transported from leaves to roots of dichlobenil treated plants than untreated plants. In Douglas fir seedlings, dichlobenil incorporated into the soil was phytotoxic to roots at 2 ppm and to lower stems (transition zone) at about 4 ppm, the lowest concentrations used. Leaching of herbicides was studied in container-grown plants, using bioassay techniques to indicated depth of phytotoxic residues. Trifluralin, nitralin and DCPA remained in the upper inch of a sand-peat mix after 2 months of daily irrigation. Dichlobenil leached 3 to 4 inches down; simazine leached to intermediate depths.

SUPPORTED BY U.S. Dept. of Agriculture

4.1013, ECONOMIC EFFECTS OF PESTICIDES AND OTHER WASTES ON NATURAL RESOURCE QUALITY

J. BINIEK, U.S. Dept. of Agriculture, Natural Resource Econ. Div., *Washington, District of Columbia* 20250 (NRE)

OBJECTIVE: Develop economic information and techniques of analysis for determining national compromises between production efficiency and adverse monetary and non-monetary effects arising from deterioration of resources quality.

APPROACH: Formal and informal cooperative relations are established with other research and action agencies to exchange information and data. Physical and economic research and information is reviewed and analyzed to determine the severity of specific pollution problems. Conceptual and qualitative studies are undertaken to improve analytical techniques for appraisal of adverse impact situations. Alternative poliution control systems are analyzed with the intent of selecting an optimum control system for policy decisions. Initial attention is given to adverse effects from chemical pesticides and animal waste.

PROGRESS: Preliminary investigations of animal waste and sedimentation problems were continued. A paper was presented at the Cornell Agricultural Waste Management Conference, January 10-13, 1969. The paper stressed the role of economics in merging the alleged conflicting goals of environmental quality and production efficiency. Contribution was also made to a paper presented at the Seminar 'Modifying the Soil and Water Environment for Approaching the Agricultural Potential of the Great Plains,' March 17-19, 1969 at Kansas State University. The paper identifies changes in livestock numbers, feedlot size and erosion as emerging problems of environmental quality.

SUPPORTED BY U.S. Dept. of Agriculture

4.1014, PESTICIDE MONITORING PROGRAM

P.A. BUTLER, U.S. Environ. Protection Agcy., Office of Res. & Monitoring, *Gulf Breeze, Florida* 32561

Cooperative program involving 15 private, state and federal laboratories who collect duplicate samples of mollusks from approximately 175 estuarine stations on Atlantic, Gulf and Pacific coasts at monthly intervals. Program initiated 1965, proposed to continue until 1969; 1500 analyses completed September 1965. Samples are sent to the Gulf Breeze Laboratory for pesticide residue analysis. Eastern oyster is chief bioassay animal, also used Mya arenaria, Mercenaria mercenaria, Ostrea luria, Crassostrea gigas and some fish species. Each sample is screened for Aldrin, BHC, Dieldrin, DDD, DDE, DDT, Endrin, Heptachlor, Heptachlor epoxide, Lindane and Methoxychlor. Analyses are made with electron capture gas-liquid chromatography techniques.

4.1015, CHEMICAL ANALYSES

A.J. WILSON, U.S. Dept. of the Interior, Bureau of Commercial Fisheries, *Sabine Island, Florida* 32561

In order to evaluate data now being obtained by a nationwide surveillance of organochlorine pesticide pollution in estuaries, studies are in progress to determine rates of uptake and the metabolism of these pollutants in marine species.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish

4.1016, DDT RESIDUES IN EGGS AND BODY TISSUES OF HENS

K.N. MAY, Univ. of Georgia, Agricultural Experiment Sta., *Athens, Georgia* 30601 (032901870111)

OBJECTIVE: Effect of forced molting and/or induced hyperthyroidism on elimination of DDT from eggs and tissues of hens contaminated with the pesticide.

APPROACH: DDT will be given to hens by capsule in amounts equivalent to .5, 1. and 5. ppm of feed intake. Some groups will be force molted by severe feed restriction and others will be fed thyroprotein. The DDT content of the tissues and eggs will be determined by gas chromotography to determine effect of treatments on elimination of residues.

PROGRESS: A study of the effect of forced molt of hens by feed restriction on rate of elimination of DDT from tissues and eggs showed that the residue in the fat of the molted hens did not decrease as fast as that in the nonmolted hens. The molted hens were using their stored fat and thereby concentrating the DDT in the remaining fat. The DDT content of eggs from the molted hens

was lower than that in the nonmolted hens when the hens first came into production. However, after one month of production the level of DDT residue in eggs from both groups was essentially the same.

SUPPORTED BY U.S. Dept. of Agriculture

4.1017, REDUCTION OF PESTICIDE RESIDUES ON FOOD AND FEED PRODUCTS

J.D. BROWN, Georgia Agric. Expt. Sta., *Griffin, Georgia* 30212 (GEO00192)

OBJECTIVE: Estimate costs of alternative techniques for the commercial reduction of pesticide residues in food and feed products.

APPROACH: Data will be obtained from federal and state regulatory agencies, and supplemented where necessary by additional survey data. This information will be utilized to make estimates of the variability of pesticide residues among market size lots of selected food and feed products; the quantity of removal from market channels of such products to insure that no product exceeding specified levels of residue tolerance would reach the consumer; the cost to the public of the product removed in terms of value of the product; and the cost of any identification, reduction, or neutralization process in the market channel. Data from secondary sources on total supply and price of specific products will be used in estimating the total quantity and value of product removal at the specified levels of tolerance. Special emphasis will be given to peaches and leafy vegetable crops in the initial stages of the work.

PROGRESS: This study indicated the absence of pesticide residues above established tolerances at the retail level of the marketing channel. It also indicated that a greater proportion of the limited number of residue violations occurred at the farm level at or before harvest except in 1967. Such results do not preclude the continued need of monitoring our food supplies for possible pesticide residue contaminations. However, they are assurances of the relative safety of our food from pesticide residues. Research should continue in the development of possible techniques of removing residues from crops (such as collards and cabbage) at harvest in marketing channels, plus education of growers in selection and use of pesticides. Manuscript 'Pesticide Residue Levels Among Fresh Fruits and Vegetables in Georgia' in process.

4.1018, BEHAVIOR OF SPECIFIC HERBICIDES IN PLANTS AND SOILS

W.S. HARDCASTLE, Georgia Agric. Expt. Sta., *Griffin, Georgia* 30212 (GEO01016)

OBJECTIVE: Investigate the absorption, translocation, accumulation, and degredation of herbicides in plants. Determine the effects of herbicides on anatomical and morphological responses, seed germination and growth, and selected metabolic systems.

APPROACH: Radiolabeled samples of the selected herbicides will be used in determining their absorption, translocation, and accumulation by plants. Root absorption will be determined both by measuring the total radioactivity accumulating in the plant and by loss of radioactivity from the rooting media. Similar procedures will be used to determine the amounts of leaf absorption. Autoradiography will be used in determining the distribution of the herbicide in plants.

PROGRESS: Plant and soil arsenic analyses by neutron activation of arsenic were reproducibly quantitative at 10 ng arsenic and might be extended to as low as 3 ng arsenic with long counting periods. This method was tested on soil and cotton (Gossypium hirsutum L. var Atlas 67) leaves treated with repeated applications of monosodium methanearsonate (MSMA). Leaves from untreated plants contained 55 ng arsenic/g whereas leaves from treated plants showed higher levels of arsenic. Total petiolar fatty acid content of sicklepod (Cassia obtusifolia L.) treated with ethydipropylthiocarbamate (EPTC) was measured by gas-liquid chromatography. Neither total petiole fatty acid content nor percents of the various 53 identified constituents changed in relation to herbicide application. Isostearate (17.5%), stearate (5.7%), oleate (5.7%), linolate (9.8%), and arachidate (8.2%) accounted for 46.9% of total petiolar fatty acid content. Derivatives of C(15) to C(31) were identified and quantitated at concentrations of 0.25 to 2.00%. Studies of changes in metabolic processes by herbicides could lead to: altered desirable component concentration; decreased undesirable component concentration; and markedly altered plant response to concomitantly applied pesticides.

4.1019, INSECTICIDE RESIDUES FROM EXPERIMENTAL TREATMENTS TO PREVENT OR CONTROL INSECTS IN STORED PRODUCTS

H. LAUDANI, U.S. Dept. of Agriculture, Market Quality Research Div., *Savannah, Georgia* 31405 (SP62)

OBJECTIVE: Provide data on deposits and residues of insecticides which can be used to guide research, to correlate chemical with biological data, to indicate toxicological hazards, and to help establish FDA tolerances for pesticides.

APPROACH: Do chemical work for all other inhouse Work Units in Branch. Improve, adapt, or develop standard chemical procedures for extraction and determination of pesticides, as necessary for specialized problems. After method routine is established, analyze samples as provided from other Work Units. Accumulate and present chemical data for cooperating stations and agencies.

PROGRESS: A total of 7,085 samples was analyzed for insecticide residues in the past year. These samples originated within the Stored- Product Insects Research Branch from experimental treatments to prevent or control insects in various stored products. The percentage distribution of the stations submitting requests was: Savannah, Ga.-- 71.2; Manhattan, Kans.--19.3; Tifton, Ga.--7.7; Richmond, Va.--1.1; and Fresno, Calif.--0.8. The percentage distribution of the analyses was: piperonyl butoxide--61.4; dichlorvos--17.1; malathion--10.7; Gardona-- 5.4; Bay 77488--2.6; total chloride--1.0; total bromide--1.0; others-- 0.8.

4.1020, ANALYTICAL INVESTIGATIONS OF PESTICIDE RESIDUES, TIFTON

M.C. BOWMAN, Georgia Coastal Pl. Expt. Sta., *Tifton, Georgia* 31794 (00ENTM0302111300)

OBJECTIVE: Determine the amount, persistence, and fate of residues of new insect control chemicals in grain and forage crops, animals, and soils.

APPROACH: Determine analytically the amount, distribution, and rate of disappearance of residues of insect control chemicals and their metabolites or breakdown products in small grain and forage crops, silage, and animals fed these products, in the milk of these animals, and in soils. Analyze pesticide formulations to be used in experiments on insect control.

PROGRESS: The field persistence of phorate in treated corn and grass forages was determined by sampling at intervals of 0-28 days. Residue analyses showed almost immediate oxidation occurred, mostly to phorate sulfoxide. Total residues at the highest rate (2 lb./acre) fell to 1 ppm after 14 days in corn and 21 days in grass. Residues remained generally stable when corn was ensiled in glass jars 1 day after treatment and aged at 85 F 30 days. Field persistence tests with Velsicol VCS-506 were sampled over 0 to 42 days. At the highest rate (2 lb./acre) residues of VCS-506 fell from 132 to 5.3 ppm after 42 days. Residues of the O-analog peaked (0.58 ppm) after 1 day and disappeared after 35; phenolic residues peaked at 7 days (2.5 ppm) then fell to 1.3 ppm at 42 days. Accothion residues in silage were fed to dairy cows for 29 days. The maximum rate (100 ppm, dry) produced 35.6, 5.6, and 0.02 ppm of the amino analog in the urine, feces, and milk, respectively, but no Accothion, O-analog, or phenolic residue in any sample. Eight days after feeding ceased no residues were detected. Corn silage field- treated with Accothion was fed to dairy cows for 8 weeks. The sole residue in the milk was a trace (0.005 ppm) of amino analog from corn treated at the maximum rate (3 lb./acre). Analysis of the silage itself showed that Accothion residues of 14.5 ppm (wet) at ensiling fell to 7.0 ppm after 8 weeks, the amino analog from 0.26 to 0.14 ppm. The hydrolyzed phenol rose from 1.8 to 3.3 ppm.

SUPPORTED BY U.S. Dept. of Agriculture

4.1021, ANALYTICAL METHODS FOR PESTICIDES, TIFTON
M.C. BOWMAN, Georgia Coastal Pl. Expt. Sta., *Tifton, Georgia* 31794 (00ENTM1102111300)

OBJECTIVE: Develop sensitive, accurate, specific methods for analysis of insect control chemicals and for their residues, metabolites, or breakdown products in grain and forage crops, animals tissues and products, and soils.

APPROACH: Study chemical and physical properties and reactions of new insect control chemicals and their metabolites to find specific measurable characteristics; develop quantitative analytical methods based on these characteristics. Develop efficient procedures for extraction and cleanup of residues from plant and animal tissues, milk, and soils preliminary to analysis. Develop gas chromatograph detectors specific for chlorinated and carbamate insecticides.

PROGRESS: An indium-sensitized flame photometric detector was designed and evaluated for the gas chromatographic determination of compounds containing chlorine, bromine, and iodine (but not fluorine). In a log-log plot the response was linear for nanogram quantities of halogenated compounds and 10,000 times greater than the response for nonhalogen compounds. A sodium sulfate-sensitized flame photometric detector was also designed and evaluated for the gas chromatographic determination of halogenated compounds. The response was linear with concentrations at nanogram or subnanogram levels. For compounds of chlorine and bromine the response was 1000 to 5000 times greater than for nonhalogen compounds. Iodine compounds give a poorer response and fluorine compounds are essentially nonresponsive. Lithium and potassium sulfates were less satisfactory than sodium sulfate for sensitization. When the detector was used to determine chlorinated pesticide residues in extracts of corn and milk no extract interference was found. A study concerning GLC retention times of 138 pesticides and metabolites containing phosphorus and sulfur on 4 thermally stable columns was completed. An analytical method was developed for Dasanit and 3 of its metabolites in corn, grass, and milk.

SUPPORTED BY U.S. Dept. of Agriculture

4.1022, DEVELOP WEED CONTROL PRACTICES FOR SOUTHEASTERN COASTAL PLAIN VEGETABLE CROPS
N.C. GLAZE, Georgia Coastal Pl. Expt. Sta., *Tifton, Georgia* 31794 (0710-03-03)

OBJECTIVE: Develop suitable weed control practices for horticultural crops in the Southeast. Determine persistence and possible metabolites of herbicides within soil and plant tissues.

APPROACH: Conduct field, greenhouse, and laboratory studies to determine the physiological effects of herbicide treatments and analyse for residues and metabolites of these compounds primarily by gas chromatography. Evaluate biological, chemical, and physical factors involved and their relationships.

PROGRESS: Weed research was conducted on direct-seeded tomatoes, peppers, lima beans, cucumbers, watermelons, turnips, and mustard greens. Nitrofen applied preemergence gave excellent weed control without injuring turnip or mustard greens. Pebulate was safer on direct-seeded tomatoes when applied 4 inches deep with sweeps than when incorporated with a rotary hoe. Diphenamid and the methyl ester of chloramben were the best treatments on peppers. The preplant application of the combination of bensulide plus naptalam appears promising on cucurbits. The methyl ester of chloramben and 2,4-bis(isopropylamino)-6-(ethylthio)-s-triazine were effective in lima bean plantings. Combinations including either trifluralin or chlorpropham as one of the components gave adequate results in lima bean plantings. Terbacil at 2 and 4 lb/A severely injured established blueberries. Simazine, floumeturon, dichlobenil, and diuron produced adequate weed control without reducing blueberry yields.

4.1023, PSEUDOCHOLINETERASE ACTIVITY AS AFFECTED BY MODERN AGRICULTURAL CHEMICALS
J.E MONTOURE, Univ. of Idaho, Agricultural Experiment Sta., *Moscow, Idaho* 83843 (IDA00466)

OBJECTIVE: To establish the effect of present day agrichemicals upon the activity of purified colostrum pseudocholinesterase. To determine the levels of anti-cholinesterase chemicals needed for detection in blood and milk. To determine whether or not it would be practical to use pseudocholinesterase activity level as an indicator for the presence of chemical residues in the blood plasma and milk of dairy animals.

APPROACH: Pseudocholinesterase will be purified from colostrum and the activity will be determined manometrically using Warburg equipment. Twelve modern agrichemicals including carbamates, organophosphorus compounds and chlorinated hydrocarbons will be used and the pseudocholinesterase activity determined in the presence of known concentrations of the chemical. The concentration of each chemical used will be dictated by its effect upon the activity of the enzyme.

PROGRESS: Summary of the data indicates that a spot test for the detection of pesticide residues appears to be practical for pesticides of the carbamate and organic phosphate group. Investigations are being continued. The spot test is based on the blue color that is formed when an esterase reacts with the substrate indoxyl-acetate. In the absence of inhibitory substances an intense blue color will develop. In the presence of either organophosphates or carbamates, the intensity of the blue color is reduced and at high pesticide concentrations, color does not develop. Presently the detection limits appear to be about the 1.0 ppm level for carbamates and slightly higher for the organophosphates.

SUPPORTED BY U.S. Dept. of Agriculture

4.1024, REDUCTION OF PESTICIDE RESIDUE HAZARDS
J. FAHEY, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (IND01533)

OBJECTIVE: Determine the fundamental physical, biochemical, and biological factors influencing occurrence, magnitude, interaction, and persistence of insecticidal chemical residues in soils, water air and raw agricultural commodities.

APPROACH: The effect of cultural practices on distribution and persistence of residues will be studied. This will include the effects of environmental factors such as temperature, relative humidity, and pH. The mechanism of translocation will be determined in greenhouse tests or growth chambers.

PROGRESS: Investigations of Gardona & Azodrin were conducted to determine practicality of using these chemicals to control insect pests to develop data that could be used to obtain tolerances and labels for their use. At recommended dosages the Gardona residues on raw vegetables and fruit varied from 1.2 to 19 ppm. Canning process removed from 97 to 100% of Gardona residues from vegetables, pears and peaches. Except with cherries, the Gardona residue found in canned fruit and vegetables was less than 0.1 ppm. Canned cherries contained 0.2 to 0.8 ppm of Gardona. In the study of Azodrin residues in green beans and tomatoes, 1.6 to 7.3 ppm of Azodrin on raw vegetables and .1 to .3 ppm of Azodrin was in canned products. Methods for the study of DDT residues in mint hay and mint oil were developed. Samples of mint hay analyzed for phygon residues contained less than 0.1 ppm. 0.05 to 0.1 ppm of chlorinated hydrocarbon residues in swine permitted to forage in corn stover or soil that had been treated for corn root pests. Methods for study of Gardona and Ronnel residues in manure were developed.

SUPPORTED BY U.S. Dept. of Agriculture

4.1025, METABOLISM AND TOXICITY OF ORGANOPHOSPHORUS INSECTICIDES
R.M. HOLLINGWORTH, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (IND01571)

OBJECTIVE: Properties of the enzyme dealkylating organophosphates. Determine the importance in detoxication and

selective toxicity. Investigate factors influencing competition between different enzymes degrading organophosphates and to set up mathematical models to describe them.

APPROACH: The occurrence and activity of the systems dealkylating methyl paraoxon will be examined in vitro and in vivo in insect and mammalian tissues. Purification of the enzyme found in the soluble fraction of the cell will be carried out by column techniques and the reaction products identified chromatographically. The activity of the system against related compounds with different alkyl groups will be examined and related to selected toxicity. Competition between this dealkylating system and other detoxifying enzyme will be studied with methyl paraoxon under varying conditions. Mathematical models of each component and of the overall detoxication will then be set up with the aid of an analog computer.

PROGRESS: Attempts to find oxidative demethylation in mouse liver microsomes with a series of dimethyl esters have not been successful and it appears that glutathione-dependent dealkylation is the major pathway of detoxication. Relationship between liver glutathione levels and toxicity of organophosphates has been examined. Several compounds strongly reduce liver glutathione levels and synergize toxicity of some dimethyl phosphate esters. A clear relationship between liver glutathione and toxicity has been established in these cases. Species differences in activity and substrate specificity are great and of probably toxicological significance. Vertebrates fall into 2 classes-- those degrading diethyl esters faster than dimethyl and those in which this order is reversed. Horse liver has the highest activity of any spp. tested. Substrate specificity of mouse liver microsomal phosphotriesterase can be explained in terms of the electron-withdrawing power of phenyl substituent (Hammett σ).

SUPPORTED BY U.S. Dept. of Agriculture

4.1026, EFFECT OF PESTICIDE RESIDUES AND OTHER ORGANO-TOXICANTS ON THE QUALITY OF SURFACE AND GROUNDWATER RESOURCES

E.J. MONKE, Purdue University, School of Agriculture, *Lafayette, Indiana* 47907

Laboratory experiments will be utilized to study sorption mechanisms of the organo-toxicant materials to mineral and organic fractions in the soil and the movement of these substances through soil profiles. Incubation studies using enrichment culture techniques will be used to isolate microorganisms capable of decomposing those materials which offer the greatest water pollution hazards. Special studies will be made to determine relationships between molecular structure and decomposability of specific toxic substances to determine the feasibility of altering molecular structures. The feasibility of treating reservoirs with special adsorbing or chelating materials in order to flocculate, precipitate, or otherwise deactivate the organo- toxicant materials or their residual decomposition products will be studied using radiological tracer techniques with model filters. Accompanying biological experiments with similar organotoxicant materials will be conducted in laboratory aquaria to determine the effects of different concentrations and synergisms.

Field studies will be conducted on well characterized, controlled watersheds and associated reservoirs to determine the effects of application practices on pollution hazards. The rate of the applied organo-toxicant materials both on the watershed and subsequently in the small reservoir will be determined possibly using radioisotope tracer techniques. Attention will be given to the development of ready means of detecting the toxic substances or its residue in water storages. Both aquatic and terrestrial indicator organisms will be used to assess the movement and concentration of the organo-toxicant, soil-borne organo toxicant, or organo-toxicant residue on the watershed and in associated small reservoirs. Samples of water, bottom muds and watershed soils will be subjected to chemical, biological and physical analyses during pretreatment, treatment, and post-treatment periods for possible organo-toxicant residue and pertinent fauna.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

4.1027, ANALYTICAL METHODS FOR HERBICIDES AND RESIDUES

E.D. SCHALL, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (IND01230)

OBJECTIVE: Develop improved methods for the analysis of herbicides and their residues, including degradation products, on plant tissues. Develop criteria for determining the tendency of a herbicide to volatilize or 'drift' from the area of application.

APPROACH: Methods having high specificity for individual compounds will be developed by the use of instrumental techniques, including gas chromatography, infrared spectral analysis, polarography, and combinations of these analytical tools. Classical methods will be employed to determine the vapor pressure to a series of 2,4-D and 2,4,5- T derivatives and to investigate vapor pressure relationships and solvents which may affect, in one way or another, the tendency of herbicides to volatize. If necessary, the vapor pressure data obtained will be correlated with biological tests.

PROGRESS: A procedure for estimating herbicide volatility by gas chromatography was developed. The vapor pressures of 24 esters of 2,4- dichlorophenoxyacetic acid (2,4-D) and 2,4,5-trichlorophenoxyaceti cid (2,4,5-T) were determined, using this technique, over the temperature range 170 to 300 C. These data were extrapolated to 25 C in order to provide data for use as a criterion of herbicide volatility under field conditions. The 25 C data support the previous gage of volatility--that a phenoxy ester with five or less carbons in the ester portion is highly volatile--and indicate that the phenoxy-type herbicides with a vapor pressure greater than 1.5 X 10 mm. of Hg at 25 C should be classified as 'highly volatile.' A solution of boron trichloride in methanol was employed for the complete transesterification of 2,4-D and 2,4-5-T esters to the corresponding methyl esters. Gas chromatographic analysis of the methyl esters permitted mixtures of 2,4-D and 2,4,5-T esters in commercial formulations to be analyzed both qualitatively and quantitatively with no sample cleanup. The method is highly specific and detected the presence of other contaminating isomers of dichlorophenoxyacetic acid. Gas chromatography was also used to qualitatively analyze mixtures of various alkyl esters of 2,4-D.

SUPPORTED BY U.S. Dept. of Agriculture

4.1028, MALATHION RESIDUES IN POULTRY MEAT AND EGGS

W.W. MARION, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010 (032901670116)

OBJECTIVE: Quantity and method of administration of malathion to chickens on residues in tissues and egg, and effect of metabolic regulators on disappearance of residues.

APPROACH: Administer P32-labeled malathion to laying hens in feed, by capsule or by spraying cages. Administer malathion to growing chickens by feed and by spraying on feathers and skin at different periods of growth. Samples of eggs, feces, liver, kidney, spleen, depot fat and pectoral muscle will be tested for presence of malathion and its metabolites. The effect of metabolic regulators on rate of disappearance of residues will be tested.

PROGRESS: The chicken is very effective in degrading malathion, for only one percent of the ingested pesticide is excreted as the intact molecule. A liver enzyme, thought to be carboxyesterase, was isolated from chicken and rat liver and partially purified. The enzyme was very effective in degrading malathion. Comparison of enzyme activity of fresh chicken liver with that of rat liver showed the enzyme activity of the former to be about one-sixth of that of the latter. Although a system was developed to separate standard solutions of malathion from its mono and diacid forms and malaoxon, the technique was not satisfactory for separating the various compounds after enzymatic degradation. The results indicate that the faster the rate of degradation, the less toxic malathion will be to an animal.

4.1030, BIOLOGY AND CONTROL OF VEGETABLE INSECTS
J.C. BOLING, Kansas State University, Agricultural Experiment Sta., *Manhattan, Kansas* 66502 (KAN00520)

OBJECTIVE: Study life history, habits, type of injury, hosts and control of insects attacking vegetable crops.

APPROACH: Study biology of insect species. Evaluate insecticides and determine rate of disappearance of residues. Study predators and parasites. Compare susceptibility of various vegetable varieties to insect attack, particularly the corn earworm.

PROGRESS: Eight insecticides were applied to sweet corn at 3-4 day intervals for 5 applications to control corn earworm. Based on the per cent worm-free ears, all treatments significantly reduced the earworm population below the check. Only Furadan performed as well as the Sevin standard.

SUPPORTED BY Kansas State Government - Topeka

4.1031, EFFECT OF PESTICIDES ON ENZYMES
B.A. CUNNINGHAM, Kansas State University, Agricultural Experiment Sta., *Manhattan, Kansas* 66502 (KAN00689)

OBJECTIVE: Test the effects of certain organophosphates and related compounds. We want to see whether these compounds inhibit soluble and mitochondrial enzymes which are currently being studied in this laboratory. Parathion and chloroxon would be typical examples of compounds to be studied.

APPROACH: The proposed work will involve spectrophotometric determination of the enzyme reaction rates in the presence and absence of the pesticide. From an analysis of the spectrophotometric data, it should be possible to determine whether inhibition exists; the type of enzymatic inhibition involved.

PROGRESS: Chloro-containing pesticides such as DDT are refractory to most enzyme systems as shown by their long biological half-life. Research was therefore initiated on the enzyme chloroperoxidase as a possible candidate for transhalogenation of organic chlorine. The organism Caldariomyees fumago (which produces chloroperoidase as an exoenzyme) was found to grow well in the presence of appreciable DDT and therefore it might be capable of metabolizing pesticide residues. The enzyme chloroperoxidase was isolated by gel adsorption, DEAE chromatography and was prepared in crystalline form. A reaction mechanism for oxidation of chloride at pH3 or phenols at pH6 was elucidated. Experiments to demonstrate transhalogenation from DDT in the presence of dimedone are not presently successful. The use of alternate halogen acceptors is planned.

SUPPORTED BY U.S. Dept. of Agriculture

4.1032, MODE OF ACTION OF INSECTICIDES
T.L. HOPKINS, Kansas State University, Agricultural Experiment Sta., *Manhattan, Kansas* 66502 (KAN00476)

OBJECTIVE: Investigate in insects and plants: Rates and routes of entry and distribution of insecticidal chemicals, intoxication processes, detoxication and excretion mechanisms.

APPROACH: Investigating modes of absorption through the integument or alimentary tract, translocation from the site of absorption, and distribution in the organs and tissues of the body. Insecticides labeled with radioisotopes are traced and assayed by radiometric techniques. Metabolic routes of intoxication or detoxication are indicated by the identification of insecticide-derived metabolites produced in the insect. Metabolites are separated by paper chromatographic methods and their presence determined by radio or enzyme assay. Routes of excretion or elimination are examined for their importance as defense mechanisms. The metabolism of systemic insecticides in mammals and plants is also under investigation.

PROGRESS: The metabolism of aromatic compounds in insects in different physiological states has been investigated with radioisotope- labeled molecules and the techniques of radiorespirometry and chromatography. Metabolism of phenylalanine (1- C-ring labeled) in cockroaches revealed aromatic ring cleavage to be of minor significance with less than 3 percent oxidized in 25 hours. Cockroaches deprived of their intracellular symbionts produced only one-eighth as much CO(2). Apparently the symbiotic bacteria perform most if not all of the aromatic ring oxidation in the insect.

SUPPORTED BY U.S. Dept. of Agriculture

4.1033, REDUCTION OF RESIDUES OF INSECTICIDAL CHEMICALS IN THE ENVIRONMENT
T.L. HOPKINS, Kansas State University, Agricultural Experiment Sta., *Manhattan, Kansas* 66502 (KAN00481)

OBJECTIVE: Determine fundamental physical, biochemical, and biological factors influencing occurrence, magnitude, interaction, and persistence of insecticidal chemical residues in soils and raw agricultural commodities, evaluate factors influencing the magnitude and mechanism of air and water pollution; develop studies related to the metabolism and detoxication of insecticidal chemical residues in animals, plants, soils and water; evaluate effects of residues of insecticidal chemicals on ecosystems on fish and wildlife; develop analytical techniques.

APPROACH: Degradation and metabolism of organophosphorus insecticides studied with environmental effects of solar radiation, temperature, and humidity. Field studies are in progress.

PROGRESS: The disappearance and residues of several organic insecticides applied to soil and corn have been studied for the fourth consecutive year in the Cedar Bluff Irrigation District. Diazinon and parathion soil treatments disappeared rapidly but heptachlor, aldrin and their epoxides persisted in slowly decreasing amounts after soil application and small residues were detected from the 1967 treatments. Corn plant samples taken from plots treated with foliar sprays of diazinon, methyl parathion and endrin showed organophosphorus residues to be very low after one month and moderate endrin residues. Wild mice trapped in the area contained small dieldrin residues. Fish collected from various river sites showed only small DDE residues. A microcolumn cleanup method has been extended to include additional pesticides and modified to handle larger samples. Photodegradation studies with five organophosphorus insecticides applied to glass and leaf surfaces both under field and laboratory conditions reveal step-wise reactions of oxidation, isomerization and hydrolysis induced by various wavelengths of radiation.

SUPPORTED BY U.S. Dept. of Agriculture

4.1034, PESTICIDE RESIDUES IN AGRICULTURAL COMMODITIES AND ENVIRONMENT
H.W. DOROUGH, Univ. of Kentucky, Agricultural Experiment Sta., *Lexington, Kentucky* 40506 (KY00480)

OBJECTIVE: To perform fundamental methodology studies including sampling, extraction, cleanup, and analysis, to participate in referee sample exchange prior to the analysis of samples from cooperative research experiments designed to solve primary residue problems in a region, to conduct fundamental studies on the fate of pesticides in plants, animals and soils including intermediate and final breakdown products; and to determine the residue breakdown of pesticide chemicals and their toxic metabolites in agricultural commodities and soil.

4. PESTICIDES

APPROACH: Existing analytical methods will be adopted and evaluated in our laboratory. Selected residue samples will be collected and exchanged with other laboratories in the area. Radiotracer techniques will be utilized to determine the fate of pesticides in plants, animals and soils. After the insecticide has been synthesized and purified it will be administered to the test organism and means of extraction will depend upon the individual compound and substrate involved. Components of the radioactive extract will be resolved by column, thin-layer and paper chromatography. Residue samples will be analyzed using colorimetry, gas chromatography, infra-red spectrophotometry and/or enzymatic techniques.

PROGRESS: Sorghum plants were sprayed twice at a 5 day interval. At the first application 50% of sorghum heads had completely emerged from the boot and when second applications were made, all of the heads had emerged from boot. Samples of whole plants were taken 20 days after last treatment and mature sorghum grain was harvested 60 days after last treatment. Insecticides and rates of application were as follows: methyl parathion - 0.5 lb/A, malathion - 1.2/A and ethion - 0.5 lb/A. Approximately 4 p.p.m. malathion and ethion residues were detected on whole plants. Residues on mature seeds were 0 p.p.m. for methyl parathion, 0.03 p.p.m. for malathion and 0.72 p.p.m. for ethion. Water-diluted sprays of GS-13005 showed a residual persistence on plants and grain very similar to that of methyl parathion. Milk from cows fed carbaryl in diet at rates of 10, 30 and 100 p.p.m. contained residues of 0.023, 0.068 and 0.278 p.p.m. carbaryl equivalents.

SUPPORTED BY U.S. Dept. of Agriculture

4.1035, BEHAVIOR OF SPECIFIC HERBICIDES IN PLANTS AND SOILS

J.F. FREEMAN, Univ. of Kentucky, Agricultural Experiment Sta., *Lexington, Kentucky* 40506 (KY00173)

OBJECTIVE: Determine the effects of climatic and edaphic factors on persistence, movement, and toxicity of two specific herbicides in selected soil types common to two or more southern states.

APPROACH: Prometryne and C-2059 (Cotoran) both promising new soil residual herbicides for southern row crops will be tested for persistence in certain important soil types of predetermined characteristics by use of a range of rates of the herbicide mixed with the soil and the resulting growth of suitable bioassay crops, grown repeatedly in the greenhouse, will be used to estimate the loss of toxicity with time in soils with the various characteristics. Leaching rate of these herbicides applied at selected rates on the surface of soil columns contained in pre-sectioned pipe will be estimated by first leaching with selected rates of simulated rainfall and then growing suitable crops in the different sections of the disassembled soil column to bioassay the amount of herbicidal residues contained at the different depths. Greenhouse bioassay of soil samples from field-treated plots taken at selected intervals after treatment will be used to estimate the toxic herbicidal residues present at different depths.

PROGRESS: A field bioassay experiment was conducted on a Maury silt loam with two herbicides. Atrazine and S6115 (2-chloro-4- cyclopropylamino-6-isopropylamino-1,3,5 Triazine) was applied pre- and post-emergent on corn with an indicator crop of Brave oats being seeded at monthly intervals after corn plants were removed. Atrazine and S6115 used pre-emergent 2 and 3 lb/A gave equal grass and broadleaf control with Atrazine 2 lb/A killing 85% and S6115 2 lb killing 60% of the oats after two months. After three months, both herbicides dropped to 45% oats killed. Atrazine 2 and 3 lb/A 1 gal crop oil applied post- emergence after 3 months still gave 85% and 93% oats killed, while S6115 applied post-emergence gave 33% and 45% oats killed. Both herbicides gave excellent grass and broadleaf control applied pre-emergent while Atrazine oil applied post-emergence appeared to be slightly better than S6115. Both gave satisfactory control.

SUPPORTED BY U.S. Dept. of Agriculture

4.1036, BIOLOGY, ECOLOGY, AND CONTROL OF INSECTS ATTACKING TOBACCO

R. THURSTON, Univ. of Kentucky, Agricultural Experiment Sta., *Lexington, Kentucky* 40506 (KY00458)

OBJECTIVE: Investigate the biology and ecology of insects (e.g. hornworms budworms, wireworms, cutworms, flea beetles, the green peach aphid, green June beetle, and grasshoppers) which feed on or damage tobacco plants; evaluate chemical control measures for preventing insect damage to tobacco; relationships between certain insects injurious to tobacco and the disease organisms, parasites, and predators affecting those insects.

APPROACH: Replicated small-plot field tests insecticides will be compared. Insecticide-treated burley tobacco will be sampled for residues analyses and smoking evaluation tests. The effect of weathering, curing, and processing on residues will be studied.

PROGRESS: Pupal diapause of the tobacco hornworm of both Kentucky and California strains was induced by short photophases and/or low temperatures. Although photophase length appears to be the major factor, diapause can be induced or prevented by low and high temperatures. Morphological differences in the pupae of the California strain are genetic and selections for these characteristics bred true. The larvae of Apanteles congregatus, a wasp parasitic on tobacco hornworm larvae, was affected adversely by nicotine, azinphosmethyl, and carbaryl incorporated in an artificial diet of the hornworm. The developmental period of hornworm larvae was lengthened and the pupal weight was reduced when they fed on diets containing carbaryl and azinphosmethyl. Imidan, azodrin, Monitor, N-2596, R-15792, C-9491, and RE-11-755 gave excellent control of tobacco hornworms and flea beetles; Monitor, C-9491, and azodrin were the most promising materials to tobacco budworm control. Diazinon, Dasanit, Bux, disulfoton, and carbofuran were the most effective materials tested for wireworm control.

SUPPORTED BY U.S. Dept. of Agriculture

4.1037, DISTRIBUTION, ABUNDANCE AND CONTROL OF HELIOTHIS SPECIES IN COTTON AND OTHER HOST PLANTS

D.F. CLOWER, Louisiana State University, Agricultural Experiment Sta., *Baton Rouge, Louisiana* 70803 (LAB01215)

OBJECTIVE: Population surveys to determine relative importance of the various hosts of Heliothis spp. Monitor insecticide resistance. Investigate the use of insect hormones for control and screen new candidate insecticides. Screen and evaluate plant characters which provide plant resistance, tolerance and non-preference to Heliothis spp. Develop new pest management systems.

APPROACH: Heliothis populations on various hosts will be surveyed throughout the season in several areas of the state and correlated with those occurring on cotton. Susceptibility to recommended insecticides will be constantly monitored by treating topically F(1) progeny reared in the lab from field collected larvae. The effects of certain hormones and hormone mimicking compounds will be studied on Heliothis and on selected beneficial insects in the laboratory. If laboratory studies show promise these will be further evaluated in small plots in the field. Promising new candidate insecticides will be routinely screened for Heliothis control in field plots at the Red River Experimental Station. plant characters which inhibit oviposition, provide antibiosis or non-preference will be evaluated in the field in randomized replicated tests at several locations in Louisiana. New pest management systems will be developed which put less dependence on insecticides.

PROGRESS: Heliothis populations in cotton presented no unusual problems during 1969. Some H. virescens activity occurred in late June and early July but these were suppressed by predators and did not require treatment. H. zea from near St. Joseph; H. zea and H. virescens from near Lacassine were subjected to topical application of M. parathion, Azodrin, Toxaphene-DDT and Carbaryl. The response indicated that these populations are still susceptible to these pesticides. Also since the Lacassine populations (S.W. La.) were susceptible this indicates that these are probably resident Heliothis and not migrants from lower Texas or other areas where insecticide resistance is common. Shell 17250 at 1 lb/A was the only insecticide tested which gave Heliothis control equal to Toxaphene-DDT, M.parathion. Bayer 93820 showed some promise. Predator populations were decreased and Heliothis populations increased following a soil application of Termik at planting.

SUPPORTED BY U.S. Dept. of Agriculture

4.1038, PESTICIDE CONTAMINATION OF ENVIRONMENT

L.D. NEWSOM, Louisiana State University, Agricultural Experiment Sta., *Baton Rouge, Louisiana* 70803 (LAB01204)

OBJECTIVE: Determine the extent to which the environment is contaminated and to develop a continuing monitoring system. Develop more satisfactory analytical techniques and methodology than those which presently exist for residues of some insecticides. Furnish pesticide analytical services to cooperating departments.

APPROACH: Amounts of insecticide residues currently present will be determined in representative samples of soil, water, bottom sediments, aquatic and terrestrial animals, and plants from five areas differing in ecology and land use. Particular attention will be devoted to developing more satisfactory techniques for determining levels of organophosphorus and carbamate residues as well as any new materials which come into widespread use. Capability for analyses can be done for all cooperating departments.

PROGRESS: Residues in fish samples from 5 monitoring sites established 3 years ago continued to reflect pesticide use. Endrin residues had virtually disappeared in fish from Bayou Chevreuil in the sugarcane area, reflecting change from endrin to guthion for control of sugarcane borer. DDT residues still high in fish from streams draining cotton producing areas. Sacks used for treated seed rice or seed corn and used second-hand for sacking feed found to be an important source of contamination of milk. Coastal bermuda forage produced on cotton farms proved to be a major source of DDT contamination; rice bran of dieldrin in milk. Residues of chlorinated hydrocarbon insecticides still ubiquitous in all species of wildlife examined. Continued work on chlorinated hydrocarbons in the Louisiana environment. Emphasis has been on residues in milk. A new and heretofore unsuspected source of contamination was discovered. Studies of residues in commercial catfish are in progress.

SUPPORTED BY U.S. Dept. of Agriculture

4.1039, BROMIDE RESIDUES AND THYROID FUNCTION

D.A. BENTON, U.S. Dept. of Agriculture, Human Nutrition Research Div., *Beltsville, Maryland* 20705 (HN2-41)

OBJECTIVE: Learn if bromide residues in fumigated wheat alter thyroid function of rats fed diets adequate and marginal in iodine.

APPROACH: Feed weanling rats diets containing methyl bromide- treated and untreated wheat with either adequate or marginal iodine. Measure metabolic rate and blood pressure at intervals. Kill at 100 or 300 days of age. Determine total and protein bound iodine and bromide in serum and thyroids. At autopsy evaluate gross changes and where indicated evaluate tissue changes histologically.

PROGRESS: A feeding study with diets containing wheat fumigated once with methyl bromide was completed. Tissue and blood samples were taken. Final evaluation of results await the analysis of samples for iodine and bromide. A second study using wheat more extensively fumigated is underway.

SUPPORTED BY U.S. Dept. of Agriculture

4.1040, METHODS OF ANALYSIS FOR PESTICIDES

K.R. HILL, U.S. Dept. of Agriculture, Entomology Research Division, *Beltsville, Maryland* 20705 (00ENTM1101210200)

OBJECTIVE: Develop sensitive, accurate, specific methods for analysis of insect control chemicals and for their residues, metabolites, or breakdown products in crops, animal tissues, milk, poultry, eggs, and soils.

APPROACH: Study chemical and physical properties and reactions of new insect control chemicals and their metabolites to find specific measurable characteristics; develop quantitative analytical methods based on these characteristics. Develop efficient procedures for extraction and cleanup of residues from plant and animal tissues, milk, and soils preliminary to analysis. Develop gas chromatographic detectors with improved specificity for different chlorinated und carbamate-type insecticides. Develop scanning and measuring instruments for sensitive quantitative thin-layer chromatographic analysis of pesticide residues.

PROGRESS: An improved colorimetric method for the analysis of hydrogen cyanide residues in vegetables was developed. It is more accurate and consistent at the 0.01 ppm level than the titrimetric methods currently in use. A fluorescence method for determining carbaryl in mixed formulations and 2-naphthol impurity in carbaryl manufactured outside of the United States was developed which is superior to existing methods based on infrared spectrometry. A method was developed for the analysis of pyrethrum extracts using quantitative thin layer chromatography. 'p' Values were determined for the gas chromatographic peaks of 8 Arochlor mixtures (polychlorinated biphenyls) in 2 pairs of solvent systems for distinguishing these compounds from pesticides during residue analyses.

SUPPORTED BY U.S. Dept. of Agriculture

4.1041, HISTOLOGICAL PROCESSING AND PATHOLOGICAL EXAMINATION OF SELECTED ANIMAL TISSUES

UNKNOWN, Litton Industries Incorporated, *Bethesda, Maryland* 20014 (NIH-70-2121)

Independently and not as an agent of the government, the Contractor will perform histologic processing and pathological examination of selected tissues from animals which were administered pesticides by the oral route under Bionetics Research Laboratories, Contract No. PH-43-67- 735. Selected treatment groups, consisting of 3,082 animals, will be examined as outlined in the attached schedule. Additionally, one negative control group of approximately 72 animals will have the same organs examined as the treated groups.

Specifically the Contractor will perform: 1. Gross examination of the selected organs. 2. Select and histologically process one appropriate section of each organ (more sections may be required in the animals with several grossly visible abnormalities). On those compounds where sections of the brain, pituitary, and thyroid glands are to be examined, the head and neck will be skinned and decalcified and then sliced coronally from front to back. 3. Pathological and neuropathological examination and reporting of the approximately 4,100 slides will be done by Dr. B.Ulland and Dr. J.R.M. Innes.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.1042, BIOLOGICAL DEGRADATION OF AGRICULTURAL INSECTICIDES

R.E. MENZER, Univ. of Maryland, Agricultural Experiment Sta., *College Park, Maryland* (MD-H-100)

OBJECTIVE: Identify and characterize the intermediates and end products of the degradation of agricultural insecticides, and investigate the mechanisms and pathways of biological degradation of insecticides.

APPROACH: Initially, studies will utilize the organophosphorus insecticides Bidrin, Azodrin, phosphamidon, dimethoate, C-2307 (CIBA Agrochemical Co.), and Mocap. The degradation intermediates that are formed as the original insecticide is converted either to stable synthetic molecules or to natural environmental constituents will be determined. For the most part, plants will be used for these studies, but soil, animals, or in vitro preparations will be used when it is apparent that more information can be obtained using these systems. Most of the studies will utilize radiolabeled insecticides, most of which it will be necessary to synthesize. Conventional chemical and radiochemical techniques of analysis will be used in characterization studies.

PROGRESS: Studies on dimethyl phosphate, ester with (N over -)- methyl-(N over -) methoxycrotonamide, C-2307, a new organophosphate insecticide, have been initiated. Preliminary studies with P-labeled C-2307 in rats have revealed the presence of two organoextractable metabolites in addition to the parent compound in urine. One of these is the unsubstituted amide analog, while the other is unidentified. Studies on the synthesis of C-labeled C-2307 are in progress so that the metabolic route of the compound in plants and further work in animals can be done. Characterization of metabolites of MOCAP in plants continues. Evidence has been obtained for the presence of ethyl propyl sul-

foxide in plants. Rats have been treated with MOCAP, but almost all of the recovered radioactivity was present in the water fraction of urine after extraction with chloroform, indicating the hydrolysis of the compound to non-toxic metabolites. Further analysis of the small amount of organoextractable radioactivity is under way. A method for the analysis of water-soluble metabolites using ion exchange column chromatography has been developed, and the water fractions from both plant extracts and rat urine will be analyzed for MOCAP metabolites in the near future. An experiment to test the behavior of MOCAP in three different soils is underway.

SUPPORTED BY U.S. Dept. of Agriculture

4.1043, BIOLOGICAL DEGRADATION OF AGRICULTURAL PESTICIDES

H.B. GUNNER, Univ. of Massachusetts, Agricultural Experiment Sta., *Amherst, Massachusetts* 01002 (MAS00240)

OBJECTIVE: Identify the products of degradation of insecticides by plants and determine quantitative significance of products. Determine the absorption and translocation of insecticides and degradation products by plants. Investigate mechanisms of decomposition of insecticides by plants.

APPROACH: Representative chlorinated hydrocarbon, organophosphate and carbamate insecticides will be applied to alfalfa, ladino clover, onion, spinach, beet, bean and carrot plants grown aseptically and under natural soil conditions.

PROGRESS: Diazinon, O, O-diethyl O-(2-isopropyl-4-methyl-6- pyrimidinyl) phosporothioate but not its hydrolysis products (2- isopropyl-4-methyl-6-hydroxypyrimidine and diethylphosphorothioate) effected sharp changes in microfloral and microfaunal population distribution. It induced ecosystem stress effects when applied directly to soil or plant, even disrupting an aquatic rhizosphere ecosystem associated with Duckweed (Lemna minor). Diazinon was found to be largely localized in the cell wall components of resistant bacteria. It was able to halt sporogenesis. Anaerobic degradation of Diazinon was enhanced by microbial metabolism.

SUPPORTED BY U.S. Dept. of Agriculture

4.1044, ENVIRONMENTAL OCCURRENCE OF N-NITROSO COMPOUNDS

G.N. WOGAN, Mass. Inst. of Technology, School of Science, *Cambridge, Massachusetts* 02139 (NIH-70-2180)

Independently, and not as an agent of the government, the Contractor shall exert its best efforts to perform a systematic study of the environmental occurrence of N-nitroso compounds.

In performing this effort, the Contractor shall: 1. Develop methodology for isolation, determination, and identification of volatile N-nitroso compounds in foods. 2. Study conditions which are favorable to the formation of various classes of N-nitroso compounds in foods and model food systems. 3. Develop methodology for isolation, determination, and identification of nonvolatile N-nitroso compounds. 4. Determine biological activity (toxicity, mutagenicity, and carcinogenicity) of novel N-nitroso compounds produced experimentally (as above) or discovered in natural sources.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.1045, MONITORING OF PESTICIDE LEVELS IN THE GREAT LAKES

R. REINERT, U.S. Dept. of Commerce, Natl. Marine Fisheries Service, *Ann Arbor, Michigan* 48107

A monitoring program to measure levels of insecticides in various species of fishes and water from each of the five Great Lakes.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

4.1046, QUALITY FACTORS OF LAKE MICHIGAN COHO SALMON FLESH

L.J. BRATZLER, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL03061)

OBJECTIVE: Determine the effect of the spawning process (period) on the quality of Coho salmon flesh. Determine the level of possible pesticide residues in Coho salmon flesh.

APPROACH: Flesh quality characteristics of Coho salmon prior to and during the spawning period will be studied. Such factors as muscle pigmentation change, muscle firmness, protein, fat, moisture, cooking shrink, and taste panel evaluation of aroma, flavor, and acceptance will be used to characterize flesh quality changes that may occur. The effect of freezing and frozen storage will be studied and would include such criteria as defrosting drip loss, rancidity measurements, cooking shrink, and taste panel evaluation. Pesticide determinations would be made on the fresh, cooked fresh, frozen, frozen stored, and cooked frozen salmon. It is contemplated using salmon from three or four periods. These would include fish samples taken from Lake Michigan sometime prior to the normal spawning period as examples of first quality Coho salmon flesh. Samples would also be taken during the spawning period to obtain information relative to quality degradation that may occur due to the physiological process of spawning.

PROGRESS: Coho salmon (78) were obtained that presented 1968 spawning or post-spawning (A); 1969 pre-spawning (B); and 1969 spawning or post-spawning (C) periods. Taste panel scores were highest for B with little difference between A and C; females were scored higher than males. Peroxide values showed more relationship (negative) to taste panel scores than percent protein, fat, moisture, or fish size. DDT levels in uncooked whole salmon steaks ranged from 2.2-13.8 ppm and were 1.7-10.2 ppm in comparable cooked steaks. Trimming fatty regions from the steak reduced residues proportional to the amount of fat removed, but never exceeded 40%. Wide variation between individual samples made comparison of residues between pre-spawning and spawning fish impossible. Results for DDE and TDE showed similar variation.

SUPPORTED BY Michigan State Government

4.1047, TRACE LEVELS OF PESTICIDE RESIDUES IN AGRICULTURAL COMMODITIES IN MARKETING CHANNELS

D.R. DILLEY, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00968)

OBJECTIVE: Methods for the prevention or reduction of pest damage or pesticide residues in agricultural commodities during transportation, processing and/or storage. Processing procedures for the removal, reduction or detoxification of pesticide residues and conversion products in agricultural commodities. Alterations of atmospheric gas composition, treatments with heated water as sprays, drenches and dips, methods to retard senescence and thus to reduce the need for pesticides; and the use of volatile gases will be tested for the control of pests. Devise and test methods and materials for protective packaging. Sterilization within the package, protection against mechanical damage and the use of protective coatings or films will be considered.

APPROACH: Examine the values of washes, water handling, brushing and heat for removal of residues. Study handling and storage sanitation procedures to reduce the need for pesticides.

PROGRESS: Thiabendazole at 250, 500 and 1000 ppm and benomyl at 75, 150 and 300 ppm applied as a post-harvest dip to apples effectively reduced fruit rot caused by Penicillium expansum. No significant effect of either was noted on fruit metabolism as measured by respiratory activity. Orchard applications are under study for this carry-over effect on the fruit during storage. Both materials reduced rot development on carrots and preliminary trials indicate some value for prestorage washes. Residue samples of materials treated with thiabendazole were supplied to the manufacturer to assist their application for clearance on apples. Ethrel hastened the maturation and red color development of Jonathan apples without apparent adverse effect on fruit keeping quality. Alar and 2, 4, 5-TP were of no effect on calcium uptake of Jonathan apples when applied to reduce internal breakdown; calcium nitrate sprays increased Ca content of the fruit and leaves, and its effect on the storage life of the fruit is under test. Paraffin as a surface coating on sugar beet roots reduced respiration and sugar loss more effectively than other coatings tested, however, the effect was insufficient to justify commercial use. Preliminary trials of sub-atmosphere pressure storage of apples

and pears as a substitute for chemical treatment to retard ripening, senescence and decay yielded results that suggest further study.

SUPPORTED BY U.S. Dept. of Agriculture

4.1048, TRACE LEVELS OF PESTICIDE RESIDUES IN AGRICULTURAL COMMODITIES IN MARKETING CHANNELS

J.T. HUBER, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00967)

OBJECTIVE: Develop procedures for the removal, reduction or detoxification of pesticide residues and conversion products in agricultural commodities.

APPROACH: Determine the effect of processing on insecticide residues in dairy products; modify present processing techniques to remove or reduce toxicity of chemical residues in dairy products. Separate and fractionate milk fat containing contaminant DDT and dieldrin into neutral lipid and phospholipids and determine the distribution of insecticide residue in each lipid class; determine with natural and model system whether insecticide is present through fat solubility or through affinity to specific components; apply ion- exchanged resin, molecular sieve and other column techniques to determine effectiveness of removing insecticide residues from milk; study the effects of spray dry on distribution and binding of insecticides in lipid classes; apply techniques developed to present processing techniques at plant level.

PROGRESS: Work is continuing on the problem of developing methods to isolate, purify and crystallize metabolites of dieldrin found in urine, feces, body fat and milk from cows. Studies of the structure of the pesticide metabolites are being made using the mass spectrometer. At present there appears to be one metabolite in milk, blood and body fat. There are five metabolites in feces. The structure of these metabolites have not been determined. It appears that dieldrin metabolites are present in animal food products but the metabolites are not being detected by the routine techniques now used to measure pesticides in meat and milk.

SUPPORTED BY U.S. Dept. of Agriculture

4.1049, TRACE LEVELS OF PESTICIDE RESIDUES IN AGRICULTURAL COMMODITIES IN MARKETING CHANNELS

N.C. LEELING, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00970)

OBJECTIVE: Processing procedures for the removal, reduction, or detoxification of pesticide residues and conversion products in agricultural commodities. Development of improvement of methods for the determination of pesticide residues in agricultural commodities.

APPROACH: Specific attention is to be directed to the determination of the actual site(s) of origin and magnitude of pesticide contamination in dairy products after they enter marketing channels. Research is planned to attempt to develop standard and more flexible techniques for routine analysis of dairy products.

PROGRESS: Following the preliminary studies of chlorinated hydrocarbon insecticide residue reduction due to cooking which was reported last year, more detailed studies were undertaken. Little difference in magnitude of residue reduction was observed due to cooking method (baking, broiling, frying, deep-fat frying or boiling). Each of these methods reduced the total DDT complex (DDT, DDE and TDE) residue level by about 25%. It was further established that trimming off the belly-flap, lateral line and dorsal fatty regions prior to cooking reduced residue levels between 30% and 40%. Thus, the trimming away of fatty regions coupled with cooking reduces chlorinated hydrocarbon insecticide residue levels in coho salmon to about one-half the level found on a fresh-weight basis.

SUPPORTED BY U.S. Dept. of Agriculture

4.1050, ECONOMICS OF PERSISTENT INSECTICIDE RESIDUES

N.C. LEELING, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00957)

OBJECTIVE: Determine the magnitude of the persistent residue problem and associated economic changes.

APPROACH: An intensified survey is proposed at the commercial grower and processor level to determine the economics of Michigan Pest Control Programs and evaluate the costs and problems of adjusting to changes in recommendations and tolerances. Detailed residue studies will be initiated to follow the build-up, degradation and movement of pesticides in relationship to normal agricultural programs.

PROGRESS: A gas chromatographic technique was developed which permits the analysis of methyl parathion with little degradation during the analysis. The system is comprised of an all-gas column and injection port with the following temperature parameters: injection port - 160 , column - 140 , detector 170 . Helium flow was 60 ml/mim. The six foot by 1/4 inch column was packed with 4% diethyleneglycolsuccinate on 60/80 mesh Gas-Chrom Q. A sodium thermionic detector was used which allowed the quantitation of residue levels as low as 0.1 ppm.

SUPPORTED BY U.S. Dept. of Agriculture

4.1051, ROLE AND FATE OF HERBICIDES, ANTIBIOTICS, ETC. IN SOILS

A.R. WOLCOTT, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00123)

OBJECTIVE: Study residual effects of herbicides, antibiotics and plant hormones in different soil types. Find effect of various compounds--herbicides and growth-regulating substances and antibiotics-- on the microbial flora of soils. Find species of bacteria which might prove helpful in bringing about disintegration of herbicides. Determine effect of biuret on plant growth, cause of transformation of urea to biuret, and biuret content of various commercial sources of urea.

APPROACH: Growth regulators and related chemicals are added to different soil types. Residual effect is then determined after regular intervals of time by either biological or chemical tests. In certain instances studies are made to determine the chemical effect on microbial activity and nitrification at different incubation temperatures of 15 , 22 , and 35 C.

PROGRESS: Nine chemicals inhibited ammonium oxidation at 2.5 ppm or less but had no effect on nitrate oxidation in the same nutrient solution cultures at 250 ppm. Two others were equally specific inhibitors of nitrite oxidation. Activity of non-anionic chemicals was greatly reduced in the presence of soil solids but not by aqueous extracts of soil. Synergism was shown for several combinations of chemicals. In perfusion systems, inhibition of ammonium oxidation by amitrole increased as nitrification proceeded and was shown to be accompanied by release of initially adsorbed amitrole into the perfusate. These results have significance for understanding side- effects of chemicals used for specific pest control purposes and suggest a multiple use for some chemicals which inhibit ammonium oxidation at very low concentrations. This effect would promote control of nitrogen stability in soils.

SUPPORTED BY U.S. Dept. of Agriculture

4.1052, EQUIPMENT AND METHODS FOR DECONTAMINATION AND DISPOSAL OF PESTICIDES AND PESTICIDE CONTAINERS

W.C. SHAW, Mississippi St. University, Agricultural Experiment Sta., *State College, Mississippi* 39762 (0710-01-32(GR))

OBJECTIVE: Determine the combustion temperatures and the volatile products of selected pesticides. Investigate the use of chemicals and other materials as aids in the decomposition of pesticides and containers. Investigate the use of indigenous soil microflora as an aid in the decomposition of pesticides in soils. Determine the requirements for pesticide containers that are readily combustible. Develop specifications for an incinerator or other device for the disposal of pesticides and containers.

4. PESTICIDES

APPROACH: Three general avenues of approach will be followed in the investigations concerning decontamination and safe disposal of selected pesticides, their formulations and pesticide containers: combustion, treatment with chemicals, and exposure to microbial flora of soils.

PROGRESS: In combustion studies, pesticide standards and formulations were ashed at 900 C and analyzed by spectrograph and X-ray diffraction. Effects of ashing will be determined after all results are keyed and read. Instrumentation and methodology were developed for analysis of volatile compounds; standard gases were characterized by gas chromatograph and mass-spectrometer. In thermal shock studies, heating of all pesticides was completed and coding is proceeding. A computerized infra-red retrieval search system was procured to facilitate anlytical work. Progress was made in the use of NaOH, sulfuric acid, and several organic solvents as decomposition aids. Mono- and triethanolamine appeared very promising for phosphate insecticides. Of 16 pesticides evaluated in soil studies with indigenous microflora, only carbaryl decomposed readily. Phenoxy herbicides also degraded but less extensively. Except for carbaryl and diuron, the pesticides inhibited microbial nitrification processes. Storage facilities were developed and six container materials - amber and clear polyethylenes, polyprolylene, polyvinylchloride, teflon, and pyrex glass- were evaluated under four temperature regimes for their effects on twenty pesticides, for pesticide effects on the containers, and for interactions between chemicals and containers. Forty-two containers have failed in the continuing test. Of five surveys on disposal methods, one was essentially completed, two others are still in progress, and two remain to be initiated.

4.1053, A STUDY OF THE HORTICULTURE SPECIALTY INDUSTRY IN MISSISSIPPI

UNKNOWN, Mississippi St. University, Agricultural Experiment Sta., *State College, Mississippi* 39762 (MIS-3-206-0732)

OBJECTIVE: Not Provided

APPROACH: Not Provided

PROGRESS: Tomatoes, spinach, turnip greens and green beans were planted from April through December. Recommended herbicides and insecticides were used to control weeds and insects. The crops were harvested at regular intervals and frozen and canned samples were obtained. Samples are being analyzed for pesticide residues, but the analyses have not been completed. The samples analyzed thus far have been below the tolerance level for the pesticide involved, for both canned and frozen samples. Pesticides used were Sevin (carbaryl), dacthal, Treflan (trifluralin).

SUPPORTED BY U.S. Dept. of Agriculture

4.1054, SCREENING AQUATIC INVERTEBRATES TO DETECT AN ORGANISM SUITABLE FOR USE IN A MONITORING PROGRAM

J.W. HOGAN, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Various aquatic invertebrates will be screened in an attempt to find one or more organisms which can be used to monitor for the presence of anticholinesterase agents. Ideally, such an organism should exhibit a reaction to levels of anticholinesterase agents which are not toxic to fish. Should such an organism be found, it could then be used to detect the presence of anticholinesterase agents beofre they can reach levels which are harmful to other members of the aquatic ecosystem. Initially, various invertebrates will be selected on the basis of availability and sensitivity to various anticholinesterase agents as indicated by bioassay test results. Dependent upon initial results, the enzyme system will be characterized in regard to optimum substrate, optimum substrate levels, both in vitro and in vivo reaction to various anticholinesterase agents, sex, date of sampling, etc. After a number of organisms have been screened, one or two of the more promising will be selected for use in an actual monitoring program in the field.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.1055, BIODEGRADATION OF PESTICIDES IN A FRESHWATER ECOSYSTEM - INTERACTION BETWEEN MICROORGANISMS AND PESTICIDES

B.T. JOHNSON, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Degradation of polychlorinated organic compounds by representative organisms from various levels of an aquatic community are investigated. Under controlled laboratory conditions microorganisms, algae, protozoa, crustacea and insects are exposed to environmental levels of both labeled and non-labeled toxaphene and chlordan. Exposure periods are varied in accordance with the organisms investigated. Degradation products are identified and characterized utilizing thin-layer and gas chromatography, infrared and mass spectroscopy, and autoradiography. Potential degradation pathways are postulated. The influence of non- pesticidal polychlorinated biphenyl compounds (PCBs) alone and in combination with chlorinated pesticides is investigated.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.1056, DEVELOPMENT OF TECHNIQUES FOR IDENTIFICATION OF PESTICIDES AND THEIR METABOLITES BY MASS SPECTROMETRY

D.L. STALLING, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

A Perkin Elmer Model 270 mass spectrometer-gas chromatograph will be installed and employed to identify pesticides and their metabolites and other compounds of interest in fish, water, and related samples. Carbon-14 labeled insecticides will be employed to aid in the separation and purification of pesticides prior to mass spectrometric examination. The study of metastable ions by defocusing normal ions will be employed and should greatly assist structure identification.

The initial efforts will be directed toward developing techniques and optimizing operating parameters as well as obtaining standard spectra of pesticides and metabolites. The use of the direct probe for introducing samples chromatographed by thin layer chromatography (introducing the sample while still on the adsorbent) will be studied. The use of capillary columns for separation of compounds by GLC will also be evaluated.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.1057, PREPARATION OF CHLORINE-36 LABELED ORGANOCHLORINE PESTICIDES AND RELATED COMPOUNDS (PCB'S)

D.L. STALLING, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

The use of radio-labeled materials greatly facilitates the determination of residue levels in acquatic organisms resulting from exposure to chlorinated pesticides or other multiple component materials such as polychlorinated biphenyls. Non-radioactive chlorinated materials will be exposed to a flux of thermal neutrons to produce radioactive chlorine-36 labeled compounds. Other short-lived byproducts will be allowed to decay and impurities resulting from radiation damage will be removed by chromatography.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.1058, IMPROVED CLEANUP PROCEDURE FOR THE REMOVAL OF LIPIDS FROM FISH EXTRACTS--CHLORINATED HYDROCARBON RESIDUE ANALYSIS

R.C. TINDLE, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

The objective of this research is to develop improved techniques for the cleanup of fish extracts. This cleanup is necessary as the fatty material removed from fish during extraction causes degradation of gas chromatographic columns and contamination of the detector, as well as giving rise to extraneous peaks which limit the sensitivity and accuracy of the analysis.

Thin-layer chromatographic techniques combined with column chromatography and sweepco-distillation will be used. The function of TLC will be primarily to follow the degree of cleanup; it may also be used as an actual cleanup procedure if the separations which it achieves cannot be achieved with column chromatography.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.1059, EVALUATION OF NATURALLY OCCURRING HALOGENATED COMPOUNDS AS POSSIBLE INTERFERENCES IN PESTICIDE RESIDUE ANALYSIS
R.C. TINDLE, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

It has recently been observed that a group of naturally occurring poly-chloro biphenyl derivatives may often constitute interferences in the analysis of pesticide residues in the environment.

The objective of this work is to review any pertinent available literature and to determine if any of the recurring interferences in our residue analysis are compounds of this type.

Extracts which contain large quantities of interferences will be concentrated and fractionated by gas-liquid and thin-layer chromatography; the resulting fractions will be examined by IR spectrophotometry to determine the presence of chlorine. Substances which are frequently found to interfere will be collected for structure elucidation.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.1060, DEVELOPMENT OF ANALYTICAL METHODS FOR SELECTED HERBICIDES
R.C. TINDLE, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

The purpose of this work unit is to survey the literature for possible methods for use with selected herbicides; and to evaluate any method which seems to show promise. The evaluation process will also include the development of modifications when necessary. Radioactive pesticides will be used when available.

When possible, GLC will be used for the analytical determination, and, consequently, it will be necessary to form derivatives of some of the compounds. Possible derivatives will be prepared on the macro scale for evaluation and for direct preparation of standard solutions.

Reports will be in the form of stepwise procedures for inclusion in the Residue Analysis Handbook. In addition, if the developed method represents a sufficiently new technique, a manuscript for publication will be prepared.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.1061, METHODS FOR EXTRACTION OF PESTICIDES FROM POND MUD PROJECT - METHODOLOGY IN CHEMICAL ANALYSIS AND SAMPLING
R.C. TINDLE, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

The purpose of this work unit is to develop satisfactory methods of extracting pesticides from pond mud. The pesticides considered will include endrin, DDT (and metabolites), methoxychlor, malathion, parathion, diazinon, carbaryl, zectran, 2,4-D, simazine, etc. The analytical methods used in the study will include GLC, TLC, and other types of chromatography, mass spectrometry, IR spectrometry, and other techniques required.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.1062, UPDATING THE 'HANDBOOK OF PROCEDURES FOR PESTICIDE RESIDUE ANALYSIS' - METHODOLOGY IN CHEMICAL ANALYSIS AND SAMPLING
R.C. TINDLE, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

The objective of this work unit is to bring together any material necessary to update the existing handbook. Periodic updating is necessary so that the handbook will reflect the current state-of-the- art in residue analysis. The report for this work unit will consist of a supplement to the handbook which should be ready for review in late fall 1971.

4.1063, ANALYSIS OF PESTICIDE RESIDUES
W.A. AUE, Univ. of Missouri, Agricultural Experiment Sta., *Columbia, Missouri* 65201 (MO00574)

OBJECTIVE: Develop an analytical services and research program for the experiment station for the analysis of pesticide residues and their metabolites in agricultural products and water. Develop simplified, rapid, and accurate quantitative gas chromatographic methods for the determination of residues of pesticides.

APPROACH: This work will be supplemented with thin layer chromatography and other instrumental methods of analysis.

PROGRESS: Service Work: Chlorinated hydrocarbons in soil, tobacco, and water. Several chlorinated hydrocarbons, thiophosphates, and carbonates in leached soils. Research: A number of gas chromatographic columns were developed, in which the liquid phase is chemically bonded to the surface of the support. These columns show excellent chromatographic behavior and minimal bleed. They have been successfully used in the analysis of chlorinated hydrocarbons. The alkali-flame detector has been modified to allow the analysis of crude soil extracts for chlorinated hydrocarbon residues without purification. At present, accuracy and precision of this method are being determined.

SUPPORTED BY U.S. Dept. of Agriculture

4.1064, HERBICIDE RESIDUE METHODS
W.A. AUE, Univ. of Missouri, Agricultural Experiment Sta., *Columbia, Missouri* 65201 (MO00473)

OBJECTIVE: Develop simplified, rapid, and accurate quantitative gas chromatographic methods for the determination of residues of herbicides, i.e., the chlorinated ureas and the symmetrical triazines such as atrazine, simazine, prometone, propazine, and prometryne. Application of the developed methodology in studies on the herbicide molecules and breakdown products present in plant tissues and soils.

APPROACH: Investigations will be conducted to determine the most efficient columns for separation, packed or capillary; types and amounts of substrates and stationary phases; optimum column temperatures, pressures, and other instrumental operating conditions; and column temperature programming.

PROGRESS: Several herbicides have been determined by microwave induced plasma emission after gas chromatographic separation. The sensitivity of detection is comparable to that using the hydrogen flame detector. Several 2-hydroxy-s-triazine metabolites have been silylated and determined by gas chromatography. An initial, twenty nanogram sample of a 2-hydroxy-s-triazine standard can be processed and detected. Studies are presently underway to develop analytical methods for picloram and methylarsonic acid.

SUPPORTED BY U.S. Dept. of Agriculture

4.1065, STRUCTURE ANALYSIS OF TRACE PESTICIDE RESIDUES BY GLC
W.A. AUE, Univ. of Missouri, School of Agriculture, *Columbia, Missouri* 65201

Several gas chromatographic detector systems (alkali-flame, microwave emission, electron capture, etc.) are adopted to give structural information on pesticide metabolites as GLC effluents. Pure decomposition products and bioextracts are derivatized and selectively determined by one or a series of detectors after gas chromatographic separation. An approximation of the empirical formula and other structural information should be obtainable with only micrograms of substance available.

The research project comprises detector and column development , the investigation on various derivatization procedures and, in the final stages of the program, practical applications of the developed methods.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.1066, TOXICOLOGY OF INSECTICIDES
C.O. KNOWLE, Univ. of Missouri, Agricultural Experiment Sta., *Columbia, Missouri* 65201 (MO00571)

4. PESTICIDES

OBJECTIVE: Develop basic studies related to the metabolism and detoxication of insecticidal chemical residues in animals and plants.

APPROACH: Studies will be conducted in vitro to determine the nature of the cholinesterase(s), aliphatic esterase(s), and phosphoryl phosphatase(s) in certain insects. Also, enzymes responsible for insecticide degradation in insects will be studied with regard to type of insecticide destroyed, site of enzymic attack on the molecule, and rate of insecticide destruction. Concurrently, the metabolic fate of certain insecticides will be investigated in plants and animals. Chromatographic, manometric, colorimetric, electrophoretic, and radioisotope techniques will be utilized.

PROGRESS: Before acaricides can be used extensively for mite control on crops, their metabolic fate in plants and animals must be studied. Degradation of the systemic acaricide N'-(4-chloro-o-tolyl)- N,N-dimethylformamidine (Galecron) occurred at a slow rate in and on apple seedlings. When Galecron was applied to the upper surface of apple leaves in situ and the leaves were analyzed after 20 days, 41% of the total applied radioactivity was recovered as the parent compound. Concentrations of Galecron in the leaves and stems (including main stems, branches, and roots) were 17 and 24%, respectively, in terms of total applied radioactivity recovered 20 days after the compound was injected into the main stem. Galecron metabolites characterized from apple seedlings included N'-(4-chloro-o-tolyl)-N-methylformamidine, N- formyl-(4-chloro-toluidine) and 4-chloro-o-tolluidine; the glucoside N- (2-methly-4-chlorophenyl)-D-glucosylamine was tentatively identified. Three benzilate acaricides, chlorobenzilate- C, Chloropropylate - C (isopropyl 4,4'-dichlorobenzilate) and GS 19851- C (isopropyl 4,4-dibromobenzilate) were applied topically to soybean leaves in situ. Analysis of the treated plants revealed that the 3 compounds were quite stable and that they were translocated to other plant tissues to a limited extent.

SUPPORTED BY U.S. Dept. of Agriculture

4.1067, MISCELLANEOUS CHEMICAL INVESTIGATIONS

E.E. FRAHM, Montana State University, Agricultural Experiment Sta., *Bozeman, Montana* 59715 (MONB00225)

OBJECTIVE: Provide for miscellaneous chemical work that is so varied in nature that it cannot be provided for by a current research project. Such chemical work is expected to be limited and of only several months' duration.

APPROACH: Chemical work undertaken is expected to require two to three months attention to complete. If answers sought are not attained in that length of time, a project specific for the problem will be initiated or the work discontinued.

PROGRESS: The Iodine and Nitrate Activity Electrodes are routinely used for the determination of Iodine and Nitrate. The procedures for these determinations have been worked out and could be written for publication after a final check against standard samples. The Vitamin A procedure has been modified from the A.O.A.C. method by using special glassware for digestion and extraction of the sample, and a short chromatographic column. These modifications need to be written up for publication when time permits. Hay, milk and fat biopsy samples have been analyzed for chlorinated insecticide residues during the past year. Analytical procedures used are those adopted from the FDA pesticides manual. Better confirmation methods are presently needed, and are being investigated. The surface lipids of Canada thistle are being investigated in cooperation with Mr. J.M. Hodgson, Assoc. Agronomist, ARS, Crops Research Division, USDA. We are attempting to correlate the surface lipid content and composition to the resistance to 2,4-D. We have identified over 80% of the surface lipids. The content and composition of ten ecotypes of Canada thistle were studied during this past summer but the data have not all been correlated.

SUPPORTED BY Montana State Government

4.1068, MECHANISMS OF THE OXIDATIVE DEGRADATION OF PESTICIDE MALEIC-HYDRAZIDE

R.D. GEER, Montana State University, Agricultural Experiment Sta., *Bozeman, Montana* 59715 (MONB00228)

OBJECTIVE: Conduct coordinated investigations into the fate of pesticide residue on or in plants, animals or soils. Such factors as metabolism growth and climatic variables may be investigated. Conduct coordinated investigations in the prevention, removal, or destruction of pesticide residues in or on treated plant parts, animals, or animal products which may enter marketing channels.

APPROACH: Reaction rates will be determined by following the course of the reaction spectrophotometrically in combination with stopped-flow reactor techniques where needed. Studies to determine the reaction products will be carried out using isotope dilution techniques, employing 14C labeled reactants. Thin-layer, column, and gas chromatography will be employed to purify reactants and isolate products.

PROGRESS: Under the above W-45 regional project title we have been investigating the rates and mechanisms for the autoxidative degradation of DDT and possible metabolic products under model environmental conditions. An apparatus for recording accurately and automatically the rate of autoxidative degradation of pesticides has been developed. Autoxidation rate data for DDT, DDE, (p-fluoro)DDD, and seven analogs (where one or more of the chlorine atoms in DDT and DDE have been replaced with hydrogen) have been obtained in chlorobenzene at 60 C both with and without cumene as co-substrate. The results indicate that under these conditions ALL the compounds investigated form free radicals which are relatively stable to oxygen and tend to inhibit autoxidation of cumene. The autoxidative rate of these compounds increases as hydrogen is substituted for chlorine in the trichloromethyl group. DDT is autoxidized very slowly under these conditions even though DDT free radicals are formed at an appreciable rate. This behavior gives some chemical rationale for why DDT is so persistent in the environment.

SUPPORTED BY U.S. Dept. of Agriculture

4.1069, DEVELOPMENT OF PRINCIPLES AND PRACTICES OF WEED CONTROL FOR NEBRASKA

G.A. WICKS, North Platte Agric. Expt. Sta., *North Platte, Nebraska* 69101 (NEB-43-002)

OBJECTIVE: Study phenological and ecological characteristics of selected weed species. Develop mechanical, cultural, and chemical weed control measures for crops in Nebraska. Study herbicide persistence and modes of dissipation.

APPROACH: Studies will be made on germination and emergence of troublesome weeds as affected by depths and dates of planting, moisture levels, and dates of seed maturation. Mechanical, cultural, and chemical weed control treatments will be directed toward finding satisfactory control methods for weeds in various crop rotations. Studies will be made on the dissipation and persistence of promising herbicides by planting sensitive crops in the field and by bioassaying soil samples taken at various crop rotations.

PROGRESS: Preplant soil incorporation treatments of pyrazon TD283, cycloate, and postemergence application of pyrazon dalapon gave better weed control and more sucrose/A than pebulate applied preplant and soil incorporated. Herbicide-treated sugarbeet plots kept weed-free by handweeding did not differ from the handweed check in sucrose production. Under most conditions, atrazine applied to sorghum at recommended rates will not persist long enough to cause yield losses of winter wheat in a winter wheat-sorghum fallow rotation. Silvex gave the best control of plains prickly pear with the least grass injury when compared with dicamba, picloram, and 2,4,5-T. Rotary hoeing just prior to spraying improved herbicide performance. Weed competition had a more marked effect on sorghum grain yields than did row spacings (20 vs 40- inch rows) or sorghum populations (42 to 50,000 vs 26 to 28,000 plants/A). Sorghum yields were reduced 4, 12, and 18% by delaying weeding of plots 3, 4, and 5 weeks as compared with 2 weeks after planting. Weeds that did not emerge until 4 weeks after planting did not reduce sorghum yields. Normal use rates of atrazine for weed control in corn applied 3 consecutive years at 3 locations across Nebraska had no significant effect on corn yield or 8 corn yield components.

4.1070, RESIDUE OF PESTICIDES - NATURE, DISTRIBUTION AND PERSISTENCE IN PLANTS, ANIMALS AND ENVIRONMENT

R.S. PARDINI, Univ. of Nevada, Agricultural Experiment Sta., *Reno, Nevada* 89507 (NEV00115)

OBJECTIVE: Investigate in detail the effect of selected pesticides on mitochondrial enzyme systems. Study metabolic alterations caused by selected pesticide ingestion.

APPROACH: Mitochondria will be isolated and the effect of selected pesticides on various mitochondrial enzymes determined by published methods. Various selected species of experimental animals will be fed residual amounts of selected pesticides and the resulting metabolic alterations established and studied. Each year the primary research effort will be on the pesticide selected for coordinated study by the W- 45 technical committee.

PROGRESS: DDT, DDE, Kelthane and Methoxychlor inhibited mitochondrial NADH-oxidase and succinoxidase activities in vitro. The site of inhibition by DDT, DDE and Methoxychlor appears to be on the substrate side of cytochrome c in the electron transport chain whereas Kelthane appears to inhibit on the oxygen side of cytochrome c. None of the pesticides checked were as potent as some of the standard electron transport inhibitors. The breakdown products of DDT, p-chlorophenol and dichlorobenzophenone showed little toxicity towards mitochondrial electron transport. Sevin was relatively non-toxic to mitochondrial electron transport. Dihydroxynaphthalene, one of Sevins breakdown products was as potent an inhibitor of mitochondrial electron transport as the most potent chlorinated hydrocarbon tested. Preliminary studies on crystalline carbonic anhydrase indicated that DDT was not a potent inhibitor of the enzyme.

SUPPORTED BY U.S. Dept. of Agriculture

4.1071, PESTICIDE RESIDUES IN ENVIRONMENT AND EFFECTS ON MARKETING AGRICULTURAL COMMODITIES

B.R. PAYNE, Univ. of Nevada, Agricultural Experiment Sta., *Reno, Nevada* 89507 (NEV00155)

OBJECTIVE: Determine what effect pesticide residues in the environment (air, water, and soil) have on the marketability of crops produced in Nevada. Determine if soils in Nevada formerly treated with DDT and other chlorinated hydrocarbons are at a safe residue level to permit crops to be grown without contamination of the crop.

APPROACH: In cooperation with members of the Plant, Soil and Water Division of the University of Nevada and the County Extension Agents, a thorough survey will be made in each of Nevada's major agricultural areas to determine the degree of contamination by pesticide residues of the air, soils and water in areas that have received heavy applications of chlorinated hydrocarbon pesticides. Many of these fields may be unsuitable for growing crops which have a zero tolerance for the chlorinated hydrocarbon pesticides; therefore affecting the marketability of Nevada's export crops. A monitoring of the same soil and water run-off areas for the substituted pesticides and their metabolites will be made to see if any future problems will arise as a result of the switch from the hard pesticides, the chlorinated hydrocarbons, the less persistent pesticides, the organo phosphates and the carbamates.

PROGRESS: In areas of alfalfa seed production, alfalfa hay is commonly grown for commercial shipment within and out of state. These areas produce over 3 million dollars annually of alfalfa hay. Seed growers use heavy insecticide dosages (usually DDT, toxaphene and Systox) to obtain good insect control. Drift of these insecticides to adjoining hay fields could affect the commercial value of hay if residue tolerances are exceeded. Surveys were made to determine the type of insecticides used in alfalfa seed areas and the potential dangers to the commercial hay growers. Drift studies were conducted in several locations and residue data was collected for DDT and toxaphene. Thirty one samples of alfalfa were analyzed for DDT and toxaphene. DDT ranged from 0.02 to 2.17 ppm residue on baled alfalfa, and toxaphene ranged from 0.1 to 4.35 ppm residue on baled alfalfa. A definite residue problem does exist when DDT and toxaphene are used in fields adjacent to commercial alfalfa hay fields.

SUPPORTED BY U.S. Dept. of Agriculture

4.1072, PESTICIDAL RESIDUES OF AGRICULTURAL CHEMICALS

B.R. PAYNE, Univ. of Nevada, Agricultural Experiment Sta., *Reno, Nevada* 89507 (NEV00106)

OBJECTIVE: Screen new pesticides and determine residues under Nevada conditions. Develop improved methods for analysis of pesticides and their degradation products. Determine pesticide results and degradation products on research and field plots in Nevada. Determine residues on hay and other agricultural commodities.

APPROACH: Develop specific methods for determining pesticide residues under Nevada conditions. Determination of residues of pesticides and their metabolites using these methods. The residue information obtained will be used to set recommended pesticide usage in Nevada.

PROGRESS: Applications of Furadan at 0.2, 0.41, and 0.64 lbs. per acre were applied to first crop alfalfa, and 15 samples were collected at various intervals for analysis by Niagara Chemical Co. Guthion was applied at rates of 0.34 and 0.46 lbs. per acre and 10 samples were collected at various dates after application for residue analysis by Chemagro. Results have not been reported. Both products may be useful in alfalfa insect control. Cubing alfalfa from the swath is a new method of handling alfalfa for feed. Eight cubed alfalfa samples were collected in the Yerington and Lovelock areas for methyl parathion analysis. Samples were analyzed to determine if cubing might affect the residues. There was no methyl parathion residue found in the cubed samples. This data agreed with data from samples of baled and dry chopped alfalfa. Due to the nesting habits of pheasants in alfalfa fields and a recent decline in Nevada pheasant populations, extensive lab and field studies were conducted on the effects of methyl parathion on 3, 10, and 17 day old pheasant chicks. Methyl parathion was applied with a ground spray rig at rates of 1/4, 1/2, 3/4, and 1.0 lbs. per acre to each of the three age groups of pheasant chicks and with aerial application at 1/2 lb. rate to the same age groups of pheasant chicks with and without brood hens in field pens. Deaths occurred at 3/4 and 1.0 lb. rates for 3 and 10 day old chicks in lab studies and with and without brood hens for 3 day old chicks in field studies.

SUPPORTED BY U.S. Dept. of Agriculture

4.1073, SEVIN PARATHION ANALYSIS

L.L. STITT, Univ. of Nevada, Agricultural Experiment Sta., *Reno, Nevada* 89507 (NEV00192)

OBJECTIVE: Determine pesticide residues from air and ground applications.

APPROACH: Determine residues on alfalfa from applications of a methyl parathion-Sevin mixture. Data obtained will be used to determine the safety in use of produce from a residue standpoint.

PROGRESS: The Sevin-methyl parathion residue study was an Union Carbide Grant-in-Aid project for 1967-68. The object was to determine the residues on or in alfalfa from the application of the mixture. Material was applied in August of 1967 by air to an alfalfa field in Lovelock and one in Yerington. The mixture was also applied by ground equipment to the plots at the Newlands Field Laboratory. The approximate rate of the mixture was 2.25 pounds which was 1.0 pound actual Sevin and 0.25 pound of methyl parathion. Green alfalfa samples were collected for residues at zero, 3, 7, and 10 days after treatment and alfalfa hay samples were obtained shortly after baling. The alfalfa was cut on the tenth day after treatment. The Division of Biochemistry- Entomology section, University of Nevada analyzed the samples for methyl parathion and Union Carbide analyzed the samples for Sevin. Methyl parathion residues were below the 1.0 ppm tolerance in the green alfalfa samples collected at 7 and 10 days after treatment and for the alfalfa hay samples. Duplicate analyses were made on the green samples from two of the three tests.

Methyl parathion residues at zero day were 7.0, 15.5, 16.5, 19.0, and 18.0. Residues at 3 days after treatment were 1.1, 2.0, 1.8, 1.7 and 1.5. Sevin analyses for all samples were below the established tolerance of 100 ppm; the range was from a high of 43 ppm to a low of 1.64 ppm.

SUPPORTED BY Nevada State Government

4.1074, CLEARANCE OF SAFE, EFFECTIVE CHEMICALS FOR MINOR USES

C.C. COMPTON, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00432)

OBJECTIVE: Evaluate current data and determine research needed for the clearance of chemicals for minor uses on agricultural products.

APPROACH: Pesticide clearances for which the chemical industries will not assume the initiative but which are desired in the public interest will be compiled for all states. Data requirements of the Food and Drug Administration and the Pesticide Registration Division for the clearance of these chemicals will be determined. Available data will be assembled from State Experiment Stations, ARS and industry. Additional data requirements will be met through the conduct of additional research in these agencies. When adequate data for the processing of a clearance on the basis of establishment of tolerance, extension of use involving a tolerance or on a no residue use is available, initiative will be taken to obtain clearance and to stimulate industry to market a product approved and labeled for the desired use.

PROGRESS: A tolerance and registered labels were obtained to cover the use of methyl parathion on sunflowers to control the head moth. Petitions have been submitted for tolerances covering the use of malathion on hops; dichlorvos and calcium cyanide on cucumbers, lettuce, tomatoes, and radishes grown in greenhouses; commercial sulfuric acid for control of weeds on onion and garlic. Label extension problems include detailed data procurement for the clearance of the milky disease bacteria, Bacillus sp. for Japanese beetle control in pastures; calcium cyanamid for the control of mummy disease on blueberries in New Jersey; (4-CPA) to improve fruit set on tomatoes; smear EQ 335 for control of screw-worm in livestock; sodium trichloroacetate as a herbicide in sugar beet and sugarcane plantings; sodium arsenite for the control of black measles, and dead arm on grapes in California; DNOC as a thinning agent for apples; 1-naphthaleneacetic acid on olives; pyrethrins and piperonyl butoxide on stored potatoes, on chickens, and for the control of blow flies on fish and meat; dichlone on mint; 4-(2,4DB) on canning peas and other legumes; 4-MCPB on canning peas, and copper arsenate on pears.

SUPPORTED BY U.S. Dept. of Agriculture

4.1075, FATE OF PESTICIDES

W.A. MACLINN, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00901)

Progress: This is a heavily supported interdepartmental research program involving 8 scientific co-investigators and 12 technicians. The study has involved the reaction of 2 herbicides and 4 pesticides on exposure to sunlight, water, plants, and soils in terms of (a) kinetics of the reactions, (b) environmental conditions affecting the reactions, and (c) identification of the intermediate and final oxidation products. At least one family of herbicides containing analine appears to be catalyzed by microbial enzymes (peroxidase) to azo compounds. Thin layer and gas chromatographic methods were devised for the separation and measurement of residues of diazinon and its possible metabolites. Photolysis products were produced from moban, metobromuron, linuron and monuron. Phototoxicity studies of the phenylurea photoproducts are in progress. Chemical oxidation of an organophosphorus compound, parathion, was studied in water. An intermediate product, Paraoxon, was formed and is considered to be more toxic than Parathion. A herbicide, diphenamid, was shown to reduce absorption of mineral nutrients from the soil in tomato plants. Linuron and chlorobromuron reduced transpiration on a leaf area basis. Degradation of Diazinon and Diazoxon was found to be a function of pH in water. These products undoubtedly have a long residual life in natural waters of a pH of 5.5 to 8.5. The biological oxidation of the herbicide 2,4-D, is tentatively assumed to result in 8CO(2) plus 2H(2) O plus 2HCL. In activated sludge systems the reaction seems to be of zero order kinetics. A technique was developed for recovery, separation and confirmation of four pesticides, their oxygen analogs and their organic hydrolysis products in aquatic environments.

SUPPORTED BY New Jersey State Government - Trenton

4.1076, PESTICIDE RESIDUES IN OR ON RAW AGRICULTURAL COMMODITIES

S.B. RANDLE, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00478)

OBJECTIVE: Develop and standardize sampling and analytical methods for the determination of pesticide residues in or on raw agricultural commodities. Determine composition and persistence of residues resulting from the use of pesticides and plant growth regulators applied to plants and animals, determine how to achieve the purpose of each use with the least residue in or on the raw agricultural product and without undue contamination of other commodities, soil, water or other parts of the environment.

APPROACH: Research will include improvement of methods of residue and metabolite determinations; and determination of residues on forage, animal products, fruits, and vegetables.

PROGRESS: Personnel submitted samples from treated plots for residue analysis. Applications were controlled and environmental factors noted. Disappearance curves were plotted. The experiments completed were: azodrin on cranberries; azodrin, dieldrin and gardona on blueberries; gardona on cranberries; and DDT on lettuce. Other samples are in analysis. Most of the work used gas chromatography for the final determination and positive results were obtained with most of the samples although many were extremely low. The object of the DDT-lettuce experiment was to determine whether a spray program could be devised so that tolerance requirements could be met without removing the outer leaves. There was only one project on development of new methods successfully completed this year. However, numerous modifications were made to accomodate existing methods to the analyses. A modified re- ignition system for the flame photometric detector was developed for use with the Micro Tek gas-liquid chromatograph and it has been submitted for publication. This information is used by our extension specialists in formulating recommendations.

4.1077, BIO-ASSAY OF SMOKE CONDENSATE FROM TOBACCO TREATED WITH AGRICULTURAL CHEMICALS

F.G. BOCK, Health Research Incorporated, *Buffalo, New York* 14203 (709-053-A102(C))

OBJECTIVE: Perform bio-assay of cigarette smoke condensate from experimental tobacco samples to determine carcinogenic activity.

APPROACH: Five cigarette samples, approximately 60,000 cigarettes per sample, will be subjected to bio-assay of smoke condensate using thirty or more rodents per sample. Cigarettes will be made of flue- cured tobaccos produced in North Carolina from fields treated with specified agricultural chemicals used for pest control.

PROGRESS:

4.1078, KIT, OPERATIONS, AERIAL DISPERSAL

R.W. UPHAM, U.S. Army, Med. Equip. Res. & Dev. Lab., *Flushing, New York* 11359

Technical Objective: To design and fabricate a kit that will be used by ground personnel in support of aerial dispersal of insecticides for control of disease vectors affecting troops in the field.

SUPPORTED BY U.S. Dept. of Defense - Army

4.1079, BIOLOGICAL DEGRADATION OF AGRICULTURAL PESTICIDES
J.B. BOURKE, New York State Agric. Sta., *Geneva, New York* 14456 (NYG00022)

OBJECTIVE: Identify and characterize intermediate and end products of agricultural pesticides and the mechanisms and pathways of their biological degradation.

APPROACH: Paper, thin layer, gas-liquid, and column chromatographic techniques will be used to isolate metabolites and end products. Characterization will involve: ultraviolet, infrared, and mass spectroscopy; chemical degradation, elemental analysis, optical rotary dispersion, autoradiographic and chromatographic techniques. Products will be bioassayed on rats and invertebrates. Studies will include effect of enzyme systems isolated from plant tissue, insects and rats. Radioactive and unlabeled materials will be employed.

PROGRESS: Toxicological experiments in which varying doses of the insecticide Torak were fed via stomach tube to male and female rats demonstrated lower LD(50) for females than males. Dietary protein did not appear to affect toxicity. This pesticide was also shown to be rapidly metabolized in both male and female rats and the three metabolites excreted in the urine (60%) and feces (40%). Urinary excretion was predominantly within 24 hours and fecal excretion essentially complete within 48 hours. Absorption of the pesticide into plants was small resulting in very minor translocation, probably as a metabolite.

SUPPORTED BY U.S. Dept. of Agriculture

4.1080, PESTICIDE RESIDUES IN OR ON RAW AGRICULTURAL COMMODITIES
J.B. BOURKE, New York State Agric. Sta., *Geneva, New York* 14456 (NYG00020)

OBJECTIVE: Determine the composition and persistence of residue resulting from the use of pesticides and plant growth regulators applied to plants and animals and determine how to achieve the purpose of each use with the least residue on or in raw products when marketed without undue contamination of other commodities such as soil, water or other parts of the environment. Develop and standardize sampling and analytical methods for the determination of pesticide residues and resulting metabolites as degradation products in or on raw agricultural commodities.

APPROACH: Analysis of residues on samples submitted by station biologists using existing methods or by the development of new methods where necessary.

PROGRESS: The pesticide laboratory has received approximately 900 samples for residue analysis of 42 different chemicals. These represented 17 categories of commodities submitted by station personnel. In addition over 150 feed samples were examined for Dieldrin in an animal feed monitoring program. Only one sample was found to be in excess of the FDA 0.05 ppm action level. Method development resulted in the adoption of the flame photometric gas chromatographic detector. Persistence of Aldicarb and Disulfoton on red raspberry after granular application was studied by laboratory bioassay of single leaves with Amphorophora agathonica to ensure continuance of control data in periods of low field populations of the aphid. Considerable variations were found within each plot. In general, control was optimal within 1-2 weeks after heavy rain and dropped near zero in dry periods.

SUPPORTED BY U.S. Dept. of Agriculture

4.1081, TRACE LEVELS OF PESTICIDE RESIDUES IN AGRICULTURE COMMODITIES
M.C. BOURNE, New York State Agric. Sta., *Geneva, New York* 14456 (NYG00104)

OBJECTIVE: Develop procedures for the removal, reduction, or detoxification of pesticide residues and conversion products in agricultural commodities.

APPROACH: An attempt will be made to devise new methods of washing to remove pesticide residues from the surface of agricultural commodities that are more effective than existing washing techniques. Fruit and vegetable commodities will be washed using new techniques that have been suggested by the fundamental studies on detergency recently published by Bourne and Jennings. In particular, the effectiveness of Dupre washing to remove residues, and methods of making the residues more easy to remove (conversion of species 2 into species 1) will be investigated.

PROGRESS: Apples sprayed with a uniform load of DDT were used to study the effectiveness of the Marangoni effect in removing pesticide residues from sprayed crops. (The Marangoni effect occurs when a solid surface passes through an air-liquid interface). The Marangoni effect removed about one third of the pesticide residue, with most of the reduction occurring in the first 20 dips through the surface, and almost no residue being removed after 40 dips. A test for saturation of the surface of the detergent solution with the removed pesticide proved negative. Agitation of the fruit in the detergent solution helps remove pesticide residue by means of the increased work function. Rome variety apples usually give up more of the DDT residue in washing treatments than do the McIntosh and Golden Delicious varieties.

SUPPORTED BY U.S. Dept. of Agriculture

4.1082, DEVELOPMENT OF APPLE SPRAY PROGRAMS IN RELATION TO SPRAY RESIDUE RESTRICTIONS
E.H. GLASS, New York State Agric. Sta., *Geneva, New York* 14456 (NYG00503)

OBJECTIVE: Develop control programs for apple pests which will produce residues within the limits established by Federal Authorities.

APPROACH: Sample fruits periodically from experimental field plots and conduct residue analyses for quantities of residual pesticides to determine degradation curves and harvest residues under orchard conditions resulting from established or new control programs.

PROGRESS: Several fruit samples were taken from control experimental plots at invervals after treatment and at harvest and sent to the manufacturers for analysis of spray residues. Six seasonal control programs were evaluated and compared with a fungicide check in orchard 12A on six apple varieties. The entire block was treated with appropriate prebloom fungicide sprays and one application of petroleum oil at tight cluster bud stage. Experimental treatments were applied at petal fall and in 6 cover sprays. All programs (Guthion, Gardona, Zolone, Imidan, GS 13005 and Furadan) gave good insect control. Golden Delicious fruits were so badly russeted by early season weather that comparisons between programs were not valid. Gardona caused lenticel enlargment on R.I. Greening and Monroe fruits. GS 13005 caused enlarged lenticels on R.I. Greening, McIntosh and Rome fruits. Residue samples were taken as needed.

4.1083, PESTICIDE RESIDUES IN AND ON RAW AGRICULTURAL COMMODITIES
W.B. DUKE, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00058)

OBJECTIVE: Determine residues of herbicides in or on forage crops from foliage and soil applications, and in animal products produced from these forage crops.

APPROACH: Established stands of bluegrass and timothy will be sprayed with 2,4-D. Residues of 2,4-D will be determined at weekly intervals on the forage produced. Seedling stands of alfalfa and birdsfoot trefoil will be treated with different rates of dalapon and the levels of residue determined at 8, 10, 12 and 16 weeks after treatment. The regrowth after an August harvest will also be sampled. The work on the development of a chemical method for 2,4,5-TP determination in forage will be continued. Crops to be studied are birdsfoot trefoil and timothy. Work will also be initiated on wheat grain under this phase of the project.

PROGRESS: During 1969, studies were conducted to determine the fate of the herbicide VCS 438 in seedling alfalfa. Initial work has been the development of an analytical method of detection of the parent material. A glc method involving column partition clean-up and electron affinity detection seems to be best. Field samplings of alfalfa treated with 2 and 4 lb/A VCS 438 have

been taken at 2, 4, 6 and 8 weeks after application and are being analyzed for parent product disappearance. Residue samples were taken from plots treated with several levels of the herbicide combination alachlor (LASSO) plus atrazine for submission to Monsanto Chemical Company. Other residue samples taken for submission to various companies involved the following material: BASF 2903-H; C- 6313; C-6989; and BASF 2903-H plus atrazine. During 1969, 1700 residue analyses were made including 19 pesticides and 17 commodities. New sensitive analytical methods were developed for 5 compounds. The metabolism of seven new agricultural chemicals (the insecticides Gardona and Hercules 14503 and the herbicides Amiben, Bromacil, Fenac, Herbisan and Planavin) were studied in dairy cows. Analysis of milk, urine and feces was conducted for these compounds and possible metabolites. The possibility of their decomposition in rumen fluid and liver microsomes was investigated to learn possible sites of metabolism. Most of this work has been submitted for publication. Research on analysis and metabolism of pesticides is essential for obtaining federal approval for pesticide use by the public.

SUPPORTED BY U.S. Dept. of Agriculture

4.1084, A STUDY OF RESIDUES RESULTING FROM GROWTH REGULATOR SPRAYS USED IN APPLE INDUSTRY

L.J. EDGERTON, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00226)

OBJECTIVE: Determine by use of tagged chemicals the amounts of residue that may result from these sprays.

APPROACH: Preliminary studies on the absorption of naphthaleneacetic acid (NAA) and naphthaleneacetamide (NAD) by apple leaves using C labeled compounds has indicated that this procedure is suitable for quantitative determination of these growth regulators. The radioactive compounds will be applied at appropriate concentrations with hand sprayer or calibrated pipette to limbs bearing sufficient fruit for periodic sampling and analysis.

PROGRESS: Orchard tests in 1969 confirmed the earlier trials on the effectiveness of preharvest sprays of 2-chloroethylphosphonic acid (Ethrel) for promoting abscission of cherries and apples. Because of the need for such a treatment in connection with mechanical harvesting of these fruit, residue and metabolism studies were conducted using C labeled Ethrel. Following application of the isotope to fruit and leaf surfaces, samples were collected for analysis periodically up to the typical harvest period 7 to 14 days after application. In both sweet and sour cherries Ethrel was found to move into the fruit from adjacent leaves with the residue reaching a peak 1 to 3 days after application. From then to harvest the level decreases as degradation of the Ethrel continues. No labeled metabolites were found to persist in the fruit. Previous work had shown that Ethrel decomposes to ethylene in fruit tissues. Similar results were obtained with apple fruits although the level in the fruit at harvest was somewhat lower than that in the cherry varieties. Good agreement was obtained between these studies with labeled Ethrel and the analytical results obtained on similar fruit samples treated conventionally with cold Ethrel and analyzed with a gas chromatograph using a method under study by the Pesticide Residue Laboratory. Further studies were made on the residues resulting from the use of Alar, alone and combination with Ethrel, on two apple varieties which were mechanically harvested for processing. Samples were collected at harvest for residue analysis and processing trials. Similar trials were also made on Alar-treated cherries and peaches.

4.1085, CYCLING AND EFFECTS OF CL36 LABELED DDT ON SOIL INVERTEBRATES IN AN OLD FIELD COMMUNITY

D.L. DINDAL, State University of New York, School of Forestry, *Syracuse, New York* 12224 (AT(30-1)3974)

The relationships of technical DDT to invertebrates in soil litter are being analyzed in a 10 A field near Urbana, Ohio. DDT residues in the invertebrates are being identified and quantified. Also, storage equilibria and magnification of residues are being determined. Treated and non-treated areas are compared, showing alterations in the invertebrate food-web relationships. This includes the lethal and sublethal effects on the quantity and quality of population densities and changes in species diversity. These objectives will clarify the ecology of non-target invertebrates as affected by pesticides.

The field use of Cl36 labeled DDT permits flexibility in realizing these goals. Assay methods for pesticide residues include liquid scintillation spectrometry, thin layer and gas chromatography, and microautoradiography. Wet and dry funnel extraction methods, and grease plating techniques are employed for invertebrate sampling.

Results: Many accurate illustrations have been made representing more than fifty microarthropod families collected in both treated and untreated sites. These are used to implement the solution of taxonomic problems thus providing understandable records for educational and reporting purposes.

Soil invertebrate population numbers on the treated site show a stimulatory response especially during Nov. and Dec. Between sample variation during each month is greater in treated versus untreated microarthropod populations. Trends in soil microbial respiration are very similar to those in microarthropod populations.

4.1086, MECHANISM OF PHOTOSYNTHESIS INHIBITION BY HERBICIDES

G. ZWEIG, Syracuse University Res. Corp., *Syracuse, New York*

Our studies indicate that certain quinone pesticides cause a disruption of the cell structure of Chlorella. In the coming year, we propose to study in greater detail the effect of quinones on the ultrastructure of Chlorella and to correlate these effects with the observed physiological-biochemical changes. Special attention will be given to characterizing the alterations in the cytoplasmic membrane by both conventional cytological and freeze-etching techniques. The possibility of damage to the cell membrane will also be investigated by studying the release of soluble cellular components from the treated cells. It is hoped that a study of the changes in the cell ultrastructure resulting from treatment with certain quinones will provide additional information on the site of action of these pesticides. It is proposed to extend this investigation to include the effects of the quinones on the ultrastructure of animal cells grown in tissue culture. Such studies will indicate if these pesticides exert effects on animal cells similar to the ones they produce in plant cells, thus enabling us to ascertain their potential as a health hazard.

We have observed that certain quinone herbicides cause an increase in sucrose synthesis accompanied by a reduction in lipids and amino acids in Chlorella. Parallel studies will be conducted to determine if these chemicals produce similar effects on the photosynthetic incorporation of CO_2 by higher plants. Also, the mechanism by which quinones and diquat alter the flow of carbon along various biosynthetic pathways in Chlorella and chloroplasts will be investigated.

The effects of photosynthesis-inhibiting herbicides like substituted ureas and s-triazines on the photosynthetic bacterium Rhodospirillum rubrum will be studied and compared with the effects on the green algae Chlorella. It is hoped such studies may demonstrate photosynthetic reactions common in aerobic and anaerobic organisms.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.1087, EFFECT OF ENVIRONMENTAL PARAMETERS ON PESTICIDAL STABILITY

Z. GAIBEL, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Natl. Insts. of Health, *Durham, North Carolina* 27709

The elaboration of the nature of the degradation products (as well as their rates of formation) of diverse classes of pesticidal agents and related derivatives is of importance in the identification of any potential hazardous agent that may be produced under environmental conditions.

The irradiation of methylenedioxy benzene derivatives such as the isomeric safroles, and the pesticidal synergist piperonyl butoxide, both per se and in polar and non-polar solvents is being in-

vestigated. The irradiation of safrole has been shown to yield a cyclic methylenedioxyphenyl derivative as well as a complex mixture of phenolic products.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.1088, METHODS OF CONTROLLING TOBACCO DISEASES WITH CHEMICALS NOT LEAVING HARMFUL RESIDUES

J F. CHAPLIN, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (0500-03-14(CA))

OBJECTIVE: Develop better methods of controlling certain tobacco diseases including brown spot, black shank, nematodes and black root rot through use of chemicals which leave no harmful residues.

APPROACH: Suitable field sites will be located where the infestation of the various diseases is moderate to high and the disease distributed uniformly throughout the test area. Plants for evaluation of the chemical treatments will include one or more resistant varieties, where available, as well as a susceptible variety. The extent of disease control will be determined by leaf and root examinations, as well as indirectly by yield of leaf produced. Leaf samples will be taken for chemical analysis, including investigations of residual compounds or metabolic products resulting from application of the chemicals.

PROGRESS: Vidden D or DD (1, 3 dichloropropene and 1, 2- dichloropropane), EB-85 (Ethylene dibromide), Telone PBC (1, 3 dichloropropene and related chlorinated C(3) hydrocarbons) and Vorlex (17 percent methyl isothiocyanate, 15 percent chloropicrin, 68 percent DD) reduced incidence of root knot. Telone PBC or Vorlex reduced the incidence of black shank of 4 varieties with resistance from low to high. Several chemicals reduced the incidence of black root rot, but none gave satisfactory control with a susceptible variety. For bacterial wilt, the most effective control and highest value increase over the untreated check were obtained when Telone PBC or Vorlex was used with highly resistant varieties. Dyrene (2,4-dichloro-6-0-chloroanilino-5-triazine), Duter TPTH (triphenyl tin hydroxide), Polyram (zinc polyethylene thiuram disulfide complex), and Maneb (Manganous ethylenebis (dithiocarbamate), and MH-30 (Diethylamine salt of maleic hydrazide) reduce the incidence of brown spot. Chemical analysis of the cured leaf suggest that the balance of alkaloids, sugars, and chlorine was not significantly affected. The bromide content in leaf treated with Telone PBC was 93 ppm compared with 36 ppm in the untreated. No residues from Mocap (O-Ethyl S, S-dipropyl phosphorodithioate) were found in rates of 8 lbs/A. Residues in cured leaf sprayed with Duter ranged from 6 to 12 ppm vs. 0.3 to 0.4 ppm in the untreated. Residues of 13 to 17 ppm were found in leaf from foliage applications of Dyrene; 13 to 18 ppm from Maneb.

4.1089, KINDS AND LEVELS OF PESTICIDES OR METABOLIC PRODUCTS IN TOBACCO LEAF AND SMOKE

J.F. CHAPLIN, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (0500-03-20(CA))

OBJECTIVE: Identification of kinds and levels of pesticides or their metabolic products in tobacco leaf and smoke condensate when treated with various pesticides.

APPROACH: Employ standard chemical methods to identify and determine levels of pesticides and sucker control agents from tobacco leaf and cigarette smoke condensate treated with these chemicals. Three types of cigarette tobaccos will be used, Maryland, burley and flue- cured. Sucker control agents used will include MH-30, Penar, and Methyl caprate. Tobacco plants will also be treated with nematocides and fungicides; and residues will be determined on the material.

PROGRESS:

4.1090, THE CONTROL OF TOBACCO DISEASES BY CULTURAL PRACTICES AND CHEMICALS

C.J. NUSBAUM, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC05028)

OBJECTIVE: Develop, evaluate, integrate efficient tobacco disease control systems involving cultural, chemical treatments - effects on pathogen ecology, tobacco yield quality, leaf analysis.

APPROACH: Long range, standarized field experiments underway and planned at selected sites involve combinations of chemical and cultural treatments to control black shank, Granville wilt, black root rot, root knot and disease complexes in varieties having different resistance levels. Field studies on brown spot control by fungicides, sanitation, cultural practices and harvesting methods. Data obtained on plant stands, growth, pathogen populations, inoculum levels, disease indices, crop yield and value, chemical and residue analysis of cured leaf. Statistical analysis of variance, treatment x location x season interactions, and inoculum x disease correlations.

PROGRESS: Factorial experiments having various combinations of control practices have shown the relative roles of host resistance, crop rotation and chemical soil treatment in complex disease situations involving root knot and black shank or southern bacterial wilt. For varieties susceptible to black shank or southern bacterial wilt, either crop rotation, chemical soil treatment, or a combination of these practices is inadequate. However, performance of resistant varieties, even those with high level resistance is greatly improved either by rotation, or soil treatment and especially by a combination of the two. Moreover, the combination of root-knot resistance with black shank or wilt resistance greatly reduces losses to these diseases whether crop rotation or soil treatment were used or not. For example, in field infested with both the root-knot and black shank pathogens, acre value for variety Coker 254 (highly resistant to both) were $1261, $1270, and $1309 for no rotation and no soil treatment, for rotation and no treatment and for treatment and no rotation, respectively. Comparable values for variety Speight G-36 (highly resistant to black shank but susceptible to root knot) were $931, $1122, and $1257. These performance data were well correlated with black shank development. Disease indices for Coker 254 ranged from 2 to 7 and for Speight G-36 from 24 to 45. In these tests, soil treatment with Telone C (dichloropropene 85% - chloropicrin 15%) was comparable in effectiveness to crop rotation.

SUPPORTED BY North Carolina State Government - Raleigh

4.1091, PESTICIDE RESIDUES IN PLANTS, ANIMALS, SOILS, AND WATER

T.J. SHEETS, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC05015)

OBJECTIVE: Perform analytical phases of research jointly undertaken by the Pesticide Residue Research Laboratory and cooperating departments on the disappearance of pesticides from plants, animals, and soils. Cooperate with IR-4 project personnel to establish tolerances and label clearances for minor uses of pesticides. Determine movement of selected pesticides in runoff from cultivated fields and downward into soil profiles and ground water.

APPROACH: Experimental samples will be collected by personnel in cooperating departments and samples will be analyzed for pesticides at different times after application. Residue data on minor uses of pesticides will be submitted to the IR-4 project coordinator to assist in developing tolerances. Under Objective 3 selected pesticides will be applied to soils under field conditions, and samples of soil and surface runoff will be collected periodically and analyzed for residues.

PROGRESS: An electron-capture gas chromatographic method was developed for the determination of trifluralin and Daxtron in soil and water. The method will detect as little as 10 ppb in soil and 1 ppb in water. Residues of DDT were determined on sweet potatoes removed from storage at several times after dusting for sweetpotato weevil control. Residues on unwashed potatoes ranged from 0.16 to 9.2 ppm. On washed potatoes the range was 0.09 to 2.3 ppm. These data were used to support a request for extension of the 7 ppm tolerance of DDT on sweet potatoes. Experiments were initiated to study (1) movement of DDT, toxaphene, and trifluralin in surface washoff from cotton fields and (2) movement and persistence of the three pesticides in soil. Preliminary results indicate that 50 percent or more of the pesticides in washoff from heavily sprayed fields was associated with suspended particulates that were retained by paper filters.

Concentrations of Daxtron in washoff from peanut fields were greatest during the first two rains after application. Thereafter, concentrations decreased rapidly to low levels (about 1 ppb). About 5% of the Daxtron applied was found in surface washoff from a sprayed sandy loam soil over a 5-month period.

SUPPORTED BY North Carolina State Government - Raleigh

4.1092, PESTICIDE RESIDUES IN AGRICULTURAL COMMODITIES AND ENVIRONMENTS

T.J. SHEETS, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC01073)

OBJECTIVE: Participate in analyses of samples from preplanned cooperative research experiments designed to solve residue problems of regional interest (cooperative sample analysis). Study the movement and ultimate fate of pesticides in plants, animals and soils including toxic intermediate and final breakdown products (Behavior). Determine the rates of disappearance of pesticide residues from agricultural commodities and environments (Dissipation).

APPROACH: Research to be conducted under Objective 1 will be planned jointly by the S-73 technical committee, and selected samples will be analyzed for pesticides in North Carolina as a part of a larger effort to determine variation in analytical results among laboratories. Under objective 2 and 3 soils and plants will be treated with pesticides and samples assayed periodically for the parent compounds and their degradation products.

PROGRESS: Residues of diazinon, chlordane, and Bayer 39007 (Baygon) on dishes in storage cabinets were determined at five intervals from 0 to 28 days after application for control of household pests. Over the 28-day period residues of diazinon decreased from 325 to 0.7 micrograms/dish; residues of chlordane dropped from 281 to 23 micrograms/dish; and those for Bayer 39007 dropped from 570 to 56 micrograms/dish. Several experiments have been initiated since this project was approved in July 1969. Research now in progress includes a cooperative study with Louisiana State University on residues of DDT, carbaryl, azinphosmethyl, and SD-8447 (Gordona) on sweet potatoes after application for sweetpotato weevil control; surveys of manufactured tobacco products and cured tobacco leaf from different market areas for insecticide residues; and the effects of oral administration of phenobarbitol and charcoal on levels of DDT in milk from contaminated cows.

SUPPORTED BY U.S. Dept. of Agriculture

4.1093, PEPTIDE HYDROLASES IN PESTICIDE METABOLISM BY PLANTS

G. GRAF, North Dakota State University, Agricultural Experiment Sta., *Fargo, North Dakota* 58103 (ND-H-02-013)

OBJECTIVE: Isolate and purify peptide hydrolase enzymes from plants. Evaluate quantitatively the role of these enzymes in pesticide metabolism.

APPROACH: Proteinases and peptidases that may be responsible for metabolism of certain pesticides (carbamates, thiocarbamates, ureas, anilides) by hydrolysis will be isolated and purified to obtain enhanced specific activities. Individual enzymes will be characterized and the kinetics and the mechanism of pesticide degradation will be investigated.

PROGRESS: N -benzoyl-DL-arginine p-nitroanilide activity is quite widespread in the roots and shoots of many crop plant seedlings. Similar activities could be detected with the related chromogenic p- nitroanilides of L-lysine, L-cystine, succinyl-L-phenylalanine, glutaryl-L-phenylalanine and L-leucine. Three amidohydrolases have been isolated from the shoots of soybean seedlings and one amidohydrolase from soybean roots has been purified fifty-fold. A soluble peptide hydrolase has been insolated from sunflower roots and purified thirty- fold through salt precipitation, gel filtration and hydroxylapatite chromatography. An attempt has been made to develop new chromogenic substrates to detect amidohydrolase activity. o-Nitroacetanilide can be used as a direct chromogenic substrate to assay enzymatic deacylation and the usefulness of this compound was demonstrated by using it as a substrate with isolation and partial purification of deacetylase enzymes. The survey for the detection of herbicide hydrolase activity seems to indicate that Taraxacum officinale (dandelion), Hordeum jubatum (squirrel tail) hydrolyzes propanil, whereas Asclepias syriaca (milkweed), Triticum durum (wheat) and Pisum sativum (pea) hydrolyzes IPC, fenuron and propanil.

SUPPORTED BY U.S. Dept. of Agriculture

4.1094, PESTICIDE RESIDUES IN AGRICULTURAL COMMODITIES

D.C. NELSON, North Dakota State University, Agricultural Experiment Sta., *Fargo, North Dakota* 58103 (ND-H-12-014)

OBJECTIVE: Effects of pesticides on acceptability and/or nutritive value of agricultural commodities.

APPROACH: Work will be concentrated on trace levels of 2,4-D in potato tubers; determine the level or residues found in potato tubers after harvest and in storage, study the effect of storage on the retension or breakdown of residues, evaluate the effects of trace levels of 2,4-D on market quality of potatoes. Residue analysis will be by standard gas chromatographic techniques on appropriate tuber samples obtained at harvest and during storage to determine levels and retension of 2,4-D. Quality will be measured by evaluation of skin color and sheen of red varieties, skin blemishes, keeping quality in storage and uniformity in size and shape, and cooking quality.

PROGRESS: Effort in 1968 has been limited to developing the methodology for and analysis of 2,4-D residues in potato tubers. A method developed earlier under this project by Smith & Klosterman for potatoes was abandoned in favor of the Yip method because of wide-spread use of the Yip method on other crops. Good quantitative results were obtained with acid fractions of 2,4-D from potatoes sprayed with 2 ounces or more of 2,4-D and analyzed after harvest, 2,4-D acid residues in samples left in storage for 6 months were too small to quantify unless rates of 4 ounces per acre or more had been used. The sample clean-up of acid fractions using the method of Yip was satisfactory. A more general procedure used for both acid and esters has not been completely satisfactory, with the ester portion particularly difficult to clean-up. The microcoulometric detector has at times picked up halogen containing compounds in the potato extracts that are naturally occurring, 2,4-D metabolites or florisil contaminants. The PGBE esters have been difficult to elute from the florisil columns, and work is continuing to develop a satisfactory technique to separate these ester(s) from potatoes. Continuing problems, particularly with our microcoulometric detecter as well as some other instruments have caused appreciable delays in this work.

SUPPORTED BY U.S. Dept. of Agriculture

4.1095, FATE AND PHYSIOLOGICAL EFFECTS OF CHEMOSTERILANTS AND OTHER COMPOUNDS

A.C. TERRANOVA, U.S. Dept. of Agriculture, Metabolism & Radiation Lab., *Fargo, North Dakota* 58103 (00ENTQ0101360100)

OBJECTIVE: Study the absorption, storage, excretion, metabolism, and mode of action of chemosterilants, certain insecticides and potential insecticides such as natural products extracted from various insect species and develop analytical methodologies for these chemicals and for their metabolites.

APPROACH: Develop analytical methodologies for those chemosterilants that probably will be used in pilot eradication tests in order to assess residue hazards and stability of the chemosterilant in medicated diets, baits, and other formulations. Determine the metabolic fate of chemosterilants in invertebrates and vertebrates. Determine the pathological, physiological, and biochemical effects of chemosterilants and potential insecticides on vital life processes in insects.

PROGRESS: Among a number of new juvenile hormone analogs synthesized, none showed unprecedented activity. The monohydrogen phosphate ion in phosphate buffers strongly attacks alkylating chemosterilants. A novel synthesis was developed for 3-aryl-2- oxazolidone. A series of phenyl aziridines and their precursors were synthesized and the activation of substituents on benezene by other substituents was determined in order to explain and predict structure activity relationships of chemosterilants. The colorimetric analytical procedure for alkylating agents

was adapted for busulfan, automated and used to determine the persistence of busulfan in boll weevils and to determine the uniformity of busulfan in medicated diets. 10-epoxy farnesenic acid ethyl ester sterilized newly emerged female house flies.

SUPPORTED BY U.S. Dept. of Agriculture

4.1096, METABOLITE FORMATION IN METABOLISM OF TRIAZINE HERBICIDES BY THE ANIMAL

E.J. THACKER, U.S. Dept. of Agriculture, Metabolism & Radiation Lab., *Fargo, North Dakota* 58103 (039900870136)

OBJECTIVE: Isolate and identify metabolites produced in animal metabolism of triazine herbicides.

APPROACH: Synthesize ring- and side-chain analogues of Propazine, Simazine, Atrazine and Prometone to administer to rats, goats, and sheep. Rats will be used to develop techniques, determine constancy of metabolism, effect of adaptation to chemical and dose level on metabolism. Lactating goats and sheep will be used to determine metabolite formation in ruminants. Techniques of isolation will include all forms of chromatography and other chemical procedures depending on chemical properties of the compound. Identification procedures will involve physical characterization by spectrometry (infrared, ultraviolet, nuclear magnetic resonance mass) and comparison with properties of synthesized hypothesized metabolites.

PROGRESS: Metabolic studies with the experimental triazine herbicide, 2-methoxy-4-ethylamino-6-sec-butylamino-5-triazine (I) and its 2-hydroxy analogues, 2-hydroxy-4-ethylamino-6-sec-butylamino-5- triazine (II), 2-hydroxy-4-amino-6-sec-butylamino-5-triazine (III), and 2-hydroxy-4-ethylamino-6-amino-5-triazine (IV) have been conducted with the rat. Compounds I, II, and III were excreted in the urine (70%) and feces (20%). Fifty percent of the administered dose of compound IV appeared in the urine. No radioactivity appeared in the expired CO(2) or as residual in the animal carcass from these compounds. The urinary excretion from compound I was separated into 16 metabolites. Four of these, constituting 90% of the urinary radioactivity, were identical to the major metabolites isolated from cow and goat urine. Ammilene (2- hydroxy-4,6-diamino-5-triazine) was the major metabolite of compound I metabolism in the rat, goat, and cow. Comparison of the metabolic pathway of compounds II, III, and IV with that of I suggests that the metabolism of these triazines by the rat may be directed by the type of substitution of the 2-position. With a 2-methoxyl group N-demethylation is extensive (90%); with a 2-hydroxyl group no N-demethylation occurred, but minor N-debutylation (9%) and significant butyl hydroxylation (79%) took place.

SUPPORTED BY U.S. Dept. of Agriculture

4.1097, METABOLISM OF CHLORINATED HYDROCARBON INSECTICIDES IN LIVESTOCK

E.J. THACKER, U.S. Dept. of Agriculture, Metabolism & Radiation Lab., *Fargo, North Dakota* 58103 (039900570136)

OBJECTIVE: Analyze physiological conditions related to metabolism of chlorinated hydrocarbon insecticides in livestock.

APPROACH: Deildrin, a typical chlorinated hydrocarbon, will be fed sheep in a factorial design with 120 head at 0, 0.5, 1.0, 2.9 mg. dieldrin per kg. body weight at restricted, carbohydrate or fat supplemented energy levels. Two treated sheep will be slaughtered at 0, 4, 8, 16 and 32 weeks. Various tissues, fluids, and whole carcass samples will be saved for fat, dieldrin, and metabolite analyses. Radiolabeled dieldrin will be administered sheep at high dieldrin intake, each energy level and slaughter period to trace metabolism and identify possible metabolites.

PROGRESS: Rats were fed three levels of dieldrin, 0.04, 0.2, and 2.0 ppm, with total feed consumption fixed. Equilibrium between dieldrin intake and excretion was reached in 42 and 49 days, respectively, by male and female rats. When the rats were killed at the end of 273 days, 5% of the total dose remained in the carcasses of the females and 2% in the carcasses of the males regardless of the level fed. Sheep are being fed two levels of C dieldrin, 0.04 ppm and 2 ppm. It appears that plateauing will also occur in sheep with the C of dieldrin being approximately equally distributed between feces and urine. Chickens have been fed diets containing 10 and 20 ppm dieldrin or 100 and 200 p,p-DDT to determine the effects of these insecticides under normal dietary conditions on egg production, shell thickness, and liver microsomal enzymes. Analysis of egg production and shell thickness data is not completed, although preliminary evaluation suggests no effect of treatment on these parameters. Hydrolylase enzyme activity was reduced in those chickens fed DDT; and demethylase and P 450 enzyme activities were higher in those fed 20 ppm dieldrin. In rats o,p'-DDA; o,p'-DDD; and o,p'-dichlorobenzhydrol have been identified as products of o,p'-DDT metabolism. Oxidized p'-DDT and DDD and these oxidized forms with an added CH(2)O group have been isolated and partially identified. An apparent conversion of o,p'-DDT to p,p'-DDT in rats has been associated with the preferential accumulation in the body fat of less than 0.1% p,p'-DDT contamination of the o,p'-DDT dose.

SUPPORTED BY U.S. Dept. of Agriculture

4.1098, GASTROINTESTINAL ABSORPTION OF AGRICULTURAL CHEMICALS IN ANIMALS

E.J. THACKER, U.S. Dept. of Agriculture, Metabolism & Radiation Lab., *Fargo, North Dakota* 58103 (039900470136)

OBJECTIVE: Identify agricultural chemical structure related to gastrointestinal absorption, effect of tissue secretions on absorption rate, chemical degradation, and gastrointestinal function.

APPROACH: Analyze gastrointestinal absorption of radiolabeled carbamate pesticides of high and low toxicities in intestinal loops and everted sacs by perfusion techniques in swine and rats. Analyze samples of perfusate, lymph, arterial and venous blood for parent compound and metabolites. Characterize mechanism of absorption. Select and synthesize structural variations of chemicals on basis of absorptive mechanism to enhance or obliterate absorption.

PROGRESS: The small intestines of male rats were divided into three equal parts and everted. The serosal space of the sacs was filled with 4 ml of Krebs-Ringer medium containing either 10 M 1-naphthyl-1- C methylcarbamate (carbaryl) or 10 M 1-naphthol-1- C at pH 6.5. The sacs were individually incubated for 2 hours in 100 ml of the same medium (mucosal fluid) under an atmosphere of 95% 0(2)-5%CO(2). After incubation, the mucosal and serosal fluids were recovered separately and lyophilized. The major polar metabolite was extracted from the dried residue and isolated by column chromatography. The major water-soluble metabolite isolated from the respective mucosal and serosal fluids of the sacs was identified as naphthyl glucuronide by comparison of its infrared spectrum with that of authentic 1-naphthyl-beta-D-glucuronide. Hydrolytic, probably enzymatic, liberation of naphthol from carbaryl, and its subsequent conjugation with glucuronic acid is apparently an active intestinal function. Hydrolysis is more active in the cranial section of the intestinal tract than in the caudal section. Substantial facilitated transport of naphthol glucuronide from mucosal to the serosal side occurred at all levels of the small intestine. However, the rate of transport in the caudal sac was approximately 3 times that in the cranial sac. These data indicate that the gastrointestinal tract plays an important function in the metabolism and/or detoxification of pesticidal chemicals.

4.1099, METABOLISM OF AGRICULTURAL CHEMICALS BY RUMEN MICROORGANISMS

E.J. THACKER, U.S. Dept. of Agriculture, Metabolism & Radiation Lab., *Fargo, North Dakota* 58103 (039900670136)

OBJECTIVE: Determine anaerobic metabolism of agricultural chemicals by ruminants.

APPROACH: Three calves will be maintained in isolation to provide predictable populations of single species of ruminal ciliated protozoa and constant bacterial populations. Agricultural chemicals (insecticides, herbicides, steroids) will be examined with these populations to determine respiration response, growth, volatile fatty acid production, use as a carbon source. Chemicals causing a microbial response will be examined further for production of metabolites and characterization of metabolites by chemical and physical methods. Ability of microbes to adapt to agricul-

tural chemical substrates will be tested by in vitro and in vivo methods. Initial experiments are to be with the triazine herbicides.

PROGRESS: Certain obligately anaerobic gram-negative bacteria isolated from rumen digesta were demonstrated to degrade tributyrin and di-n-butyl succinate (Tabutrex). Sonified cell preparations of these bacteria degraded alpha-naphthylacetate to alpha-naphthol and acetic acid, and fluorescein 3', 6'-diacetate (FDA) to fluorescein and acetic acid. Incubation of the sonified cell preparations with pesticides for 30 minutes, followed by a FDA assay for esterase activity, indicated that Mobam, Bidrin, Paraquat, and Phosdrin were inhibitory at the 50% level. Other compounds showing inhibition of esterase activity were alpha-naphthol, Tabutrex, lauryl sulfate, sodium fluoride, manganese chloride, cobalt chloride, and tributyrin. No inhibition was shown by NaCl, acetylcholine chloride, Trifluralin, and IPC. An acetone precipitate from a sonified isolated rumen bacteria degraded FDA, alpha- naphthyl acetate, and Mobam. The degradation of Mobam with the acetone precipitate appears to be enzymatic and specific. Snake venom 'esterase' did not degrade Mobam. Trifluralin, a herbicide, has been shown to be degraded by rumen microflora. The bacterium Selenomonas ruminantium has been shown to degrade Trifluralin to similar products. Methallibure, an estrous control agent, is not degraded by rumen digesta when incubated in the dark. Methallibure was shown, however, to be unstable to fluorescent light, with the resultant formation of a thiadiazole by the loss of H(2)S to form a ring-structured compound.

4.1100, METABOLIC FATE OF PESTICIDES IN ANIMALS

E.J. THACKER, U.S. Dept. of Agriculture, Metabolism & Radiation Lab., *Fargo, North Dakota* 58103 (039900370136)

OBJECTIVE: Determine metabolic fate of pesticides in terms of quantitative distribution of compound and metabolites in animal tissues, milk and excreta.

APPROACH: Administer in a single oral dose radiolabeled pesticides to rats, sheep, and lactating goats and cows. Collect and analyze respired CO(2), urine, feces, milk, organs, and tissues for distribution of radioactivity. The radiolabel will be generally C with, if necessary, both the ring-and the side-chain-labeled compound used. Experiments will employ at least 14 rats and 2 sheep, goats, and/or cows. CO(2), urine, feces, and milk will be collected at periodic intervals over a period of 72 hours. Tissue samples will be taken from liver, heart, blood, muscle, kidney and omental fat, kidney, spleen, lung and brain. Metabolic fate of triazine herbicides is currently being determined.

PROGRESS: A series of sheep have been dosed with the C ring- labeled and C side-chain labeled sheep defleecing chemical, cyclophosphamide (2- bis(2-chloroethyl)amino tetrahydro-2H-1,3,2- oxazophosphorine-2-oxide). Seventy-two hours after dosing with the ring-labeled, chemical, 99% of the radioactivity was recovered with the urine containing 84%, feces 6%, and expiratory CO(2) 9%. With the side- chain labeled compound, 96% of the radioactivity was recovered in the urine, 4% in the feces, and 1.8% in the expiratory CO(2) 72 hours after dosing. Residual radioactivity was determined in various organs and tissues of sheep 24, 48, and 72 hours after dosing with radiolabeled cyclophosphamide. Calculations of the time required to reduce tissue residues by one-half gave values of approximately 24 hours. This suggested that residues of cyclophosphamide equivalents would be reduced to levels of 0.01 ppm in 10 days or less. Determination of residues in tissues of sheep slaughtered 7 days after dosing did not verify this calculation. Examination of the data indicated that cyclophosphamide had been metabolized to the extent that a portion of its radioactive carbon had joined the anabolic carbon pool of the body. Cyclophosphamide was metabolized to at least six urinary metabolites. Tentatively, the major metabolite has been identified as oxidized cyclophosphamide.

4.1101, PHOTOLYSIS OF PESTICIDES

D.D. BILLS, Oregon State University, School of Agriculture, *Corvallis, Oregon* 97331

The objectives of this proposal are: 1. To evaluate photolysis coupled with gas chromatography as an analytical method for the identification of certain pesticide residues in foods. 2. To identify photolytic products of certain pesticides irradiated with ultraviolet light under laboratory and field conditions. 3. To investigate the parameters influencing the photolysis of certain pesticides.

Photolysis of pesticides will be carried out in model systems and in selected food systems following clean-up procedures. The degradation pattern as detected by gas chromatography will be evaluated as a means of confirming the identity of each pesticide. Identification of hitherto unidentified products of photolysis will be made by mass spectrometry, infrared spectroscopy and other means. The parameters influencing degradation will be investigated, and mechanisms of degradation will be elucidated when possible. Photolysis under both laboratory and field conditions will be studied.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.1102, PESTICIDE RESIDUES IN FOOD PRODUCTS

L.C. TERRIERE, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00085)

OBJECTIVE: The development of suitable methods for the measurement of pesticide residues on or in food products entering market channels. Use of these methods in cooperation with pest control specialists to develop control measures with minimum pesticide residue hazards. The study of the metabolic fate of pesticides in plants and animals.

APPROACH: Projects will be planned and executed in cooperation with other scientists, such as entomologists or engineers, so that both field and laboratory phases of the work are covered. In the case of the basic studies the experiment will involve intact plants or experimental animals or they will use in vitro systems prepared from plant or animal tissues. In the case of research aimed at the establishment of tolerances or label registrations the final step will be the preparation of an adequate technical report describing the experiments and the results.

PROGRESS: The development of methods for measuring pesticide residues in hops and in peppermint hay and oil received major emphasis during the year. Two phosphate insecticides, phorate and disulfoton, were applied to hops in Oregon and Washington and samples collected at intervals up to and including harvest. The analyses which have been completed show that the soil or foliage treatment of hops results in total residues, for parent compound and all metabolites, of less than 0.2 ppm on dry hops. This information supplements that gathered last year and will support registration requests for these pesticides. Similar tests with azodrin have not been completed. Phorate and azodrin were applied to peppermint in Washington and Oregon and samples collected during the season are being analyzed. Results to date show that peppermint oil from fields treated with phorate contain up to 2 ppm combined phorate and metabolites. The work on azodrin has not been completed. The loss of insecticides during and immediately after their application to the soil was studied with the insecticides dyfonate and zinophos. The application process was monitored at several points by analysis of appropriate samples. The data show that approximately 25% of the insecticides are lost during application. Root tissue of seedling bean, pea, and corn has been compared as a source of the enzyme system which converts aldrin to dieldrin. Conversions of up to 12% of the substrate have been achieved.

SUPPORTED BY U.S. Dept. of Agriculture

4.1103, ANALYTICAL METHODS FOR PESTICIDES AND PESTICIDE DEGRADATION PRODUCTS

C.D. ERCEGOVICH, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01527)

OBJECTIVE: Development of improved analytical methods for residues of pesticides and their degradation products.

APPROACH: Existing methods for the determination of pesticide residues and degradation products will be critically examined for sensitivity, accuracy, reproducibility and simplicity. Special emphasis will be placed on pesticides in common use, and on pesticide degradation products, soil, water, and other media.

PROGRESS: Compounds possessing nitro groups are reduced to the corresponding amino group, then diazotized with nitrous acid and coupled to fibrinogen. Antibodies of the azoprotein are developed in rabbits over a 30-day period. Ring precipitation and passive hemagglutination tests demonstrate that the antibodies yield a high degree of specificity to dilutions of 1:10 parts of azoprotein antigen, but that impurities in the antigen cause undesirable cross reactions. Improved methods for removal of impurities from azoprotein and changes in injection schedule may increase specificity, sensitivity and reduce cross reactions. Present methods for analysis of CIPC residues in alfalfa and clover are unsatisfactory. A more efficient method has been developed using the Bleidner apparatus for hydrolysis and recovery of CIPC and cellulose column chromatography for removal of interfering plant materials after color development. The procedure is sensitive to .04 ppm. Work indicates possibility of detecting less than 1 ng of chlortriazines by electron capture GLC. Method is based on reacting the herbicide with HFBI and using an OV-210 column. Search for proper reaction conditions for soil and plant samples is necessary to achieve same sensitivity attainable with in vitro samples. Separation of chlorotriazines from their metabolites in ethanolic plant extracts by ion-exchange chromatography has been restudied.

SUPPORTED BY U.S. Dept. of Agriculture

4.1104, FATE AND PERSISTENCE OF PESTICIDES AND PHYSIOLOGICALLY ACTIVE DEGRADATION PRODUCTS

D.E. FREAR, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01532)

OBJECTIVE: Follow the disappearance of pesticide residues in media other than raw agricultural commodities. Qualitatively and quantitatively identify the degradation products resulting from the breakdown of pesticide residues in media other than raw agricultural commodities.

APPROACH: Measure quantitatively pesticide residues remaining at known time intervals following application in various types of soils, water, plant by-products, silage, dairy products, feed stuffs. By gas chromatographic methods. Identify and measure any pesticide degradation products which may result from hydrolysis or decomposition caused by heat or processing or other physical or chemical forces. These will be separated by thin layer, column or gas chromatographic means and identified by infrared or other spectral analyses and the use of labelled compounds.

PROGRESS: The disappearance of total chlorphenamidine and its metabolites during the growing season and the residue of these materials at harvest on six fruit crops and Hagerstown silt loam soil has been studied. Of three identified metabolites only N-formyl-2-methyl-4- chloroaniline and the parent compound were found at harvest. Neither chemical nor enzymatic degradation appear to occur in any of these crops. Environmental factors and growth dilution seem most responsible for its disappearance from fruit. The half-life of total chlorphenamidine residues in soil of 20% moisture at 20 C is about 20 weeks. Microbial activity seems to be primarily responsible for its disappearance from soil. Trace amounts of 4,4'-dichloro-2,2'- dimethylazobenzene (DDAB) were detected after six months in non-sterile but not in sterile soil treated with 2000 ppm of chlorphenamidine. The formation of DDAB under field conditions through the practical use of chlorphenamidine appears to be of little significance. The uptake of DDAB in cabbage and corn plants grown in soil containing 50 and 500 ppm was detected at 14 days, but not at 50 days. Evidence of DDAB degradation in corn and cabbage plants has been observed by thin layer chromatography. The persistence of aminotriazole, dalapon, diuron, paraquat and simazine in orchard soils has been investigated and long term studies of Lovozal have been initiated.

SUPPORTED BY U.S. Dept. of Agriculture

4.1105, DEVELOP MICROANALYSES FOR DETECTION OF HERBICIDES AND METABOLITES IN PLANT TISSUE

C.R. SWANSON, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (0750-09-07-(GR))

OBJECTIVE: Develop new methods and adapt existing methods for the detection of herbicides and determine the sites of accumulation of herbicides and their metabolites in plant tissues and cells.

APPROACH: Representative major herbicides will be tritium labeled and used to treat experimental plants. The harvested plants will be radioautographed by macro and micro methods in order to localize the herbicide and its metabolites. Biochemical separation techniques will also be employed. Other procedures to be explored as possible means of micro detection and assay include microspectrophotometry, specific staining, fluorescence tagging, electron probe detection, and mass spectrometry of gas chromatography effluents.

PROGRESS: A major metabolite of (2,4-dichlorophenoxy)acetic acid (2,4-D) in bean plants was shown to be 2,5-dichloro-4- hydroxyphenoxyacetic acid. A minor metabolite was 2,3-dichloro-4- hydroxyphenoxyacetic acid. Both products existed primarily in plant as glycosides. These metabolites also occurred in wheat and oat plants, but in these species the major metabolite was the glucose ester of 2,4- D. The other major research project, in which the data are not yet fully evaluated, consisted of cytological studies with soybean leaf or callus tissue cells treated with tritiated 2,4-D, atrazine, or diuron to determine sites of localization within the cell. A major metabolite of atrazine in sorghum plants contained both hydroxyatrazine and amino acid residues.

4.1106, AEROBIC AND ANAEROBIC BIODEGRADATION OF DETERGENTS

A.J. STIRTON, U.S. Dept. of Agriculture, Eastern Utilization Res. Div., *Wyndmoor, Pennsylvania* 19118 (E6-3-92)

OBJECTIVE: Develop new uses for inedible animal fats through studies on the mechanism of aerobic and anaerobic biodegradation of fat- based detergents and surface active agents.

APPROACH: The mechanism of biodegradation will be investigated by a method which permits automated analyses for chemical oxidation demand, methylene blue active substance and sulfate ion. Anaerobic biodegradation will be studied by a method based on the volume of methane evolved. Other methods for measuring biodegradation will also be explored. Results will direct the development of improved detergents and help solve present water pollution problems.

PROGRESS: A method for following the course of aerobic biodegradation of anionic detergents by automated analysis for C, MBAS (Methylene Blue active substance) and sulfate ion showed tallow alcohol sulfates, ether alcohol sulfates, alpha-sulfo esters and linear alkylbenzenesulfonate (LAS) to decrease in ease of biodegradation in that order. Completely anaerobic conditions for biodegradation are seldom realized but are approximated by relatively common microaerophilic conditions under which biodegradation occurs at a low oxygen level of about 1 ppm or less. A method based on the river water test was developed for simultaneous measurement under both aerobic and microaerophilic conditions. Tallow alcohol sulfates, sulfated alkanolamides, ether alcohol sulfates, alpha-sulfo esters and LAS were examined. Tests were carried out in river water containing 5 or 10 ppm of the detergent at 25 or 35 C. Aerobic and microaerophilic experiments were stirred by a continuous stream of air or nitrogen, respectively. Biodegradation was followed by analysis for MBAS using an autoanalyzer. Tallow alcohol sulfates and tallow-based sulfated alkanolamides were the most easily degraded under either condition and LAS the most resistant.

SUPPORTED BY U.S. Dept. of Agriculture

4.1107, AGRICULTURAL CHEMICAL RESIDUES IN PLANT AND ANIMAL PRODUCTS

J. SINGMASTER, Univ. of Puerto Rico, Agricultural Experiment Sta., *Mayaguez, Puerto Rico* (PR00104)

OBJECTIVE: Development, of chemical, instrumental and biological methods of residue analysis. Behavior of chemicals as related to residues in agricultural commodities. Residues and their metabolites in agricultural commodities and in their environment.

4. PESTICIDES

APPROACH: Gas chromatography with an electron capture detector will be used for analysis of pesticides especially Di-Syston. Studies on adaptation of existing methods of pesticide residue analysis will be made on such tropical crops as sugarcane, pineapple, coffee, pigeon peas, plantains, yautia (tanier Xanthosoma Caracu) and yuca (cassava, Manihot Esculenta). Studies of the residues of Di-Syston in leaves of coffee, pineapple and sugarcane from soil applications under different conditions will be made. The discovery that 'green coffee' beans have almost undetectable residues from recommended Di-Syston applications while the pulp from same treatment has up to 3 ppm will be examined, possibly with radioactive Di-Syston, to see if Di-Syston or its metabolites ever enter the bean. Determination of residues and their metabolites will be done in the following crops: for Di-Syston: in tomatoes, lettuce, peppers, and cabbage; for DDT: papaya and pigeon peas; for Diazinon: in pangola grass and sugarcane; for Parathion: in coffee; for Sevin: in pangola grass; for Dieldrin: in yams, yautia, yuca, coffee, and plantains.

PROGRESS: A new extraction procedure for residue analysis in various fruit pastes was successfully developed, as well as an analytical method for Ametryne in tuber crops and pigeonpeas. The latter method, slightly modified, may also be applied to coffee. Analysis of DDT in pigeon peas revealed residues up to 3 ppm in peas from plants treated 15 to 23 days before harvest using several spray schedules. Several small samples that had to be hand shelled had considerably less (ca. 1/3) residue than other replicates with the same treatment, which were machine-shelled. Studies were conducted on a U.V. method for analysis of toxaphene residues without success so far. A new method for urea herbicide analysis was tested, but results were unpromising.

SUPPORTED BY U.S. Dept. of Agriculture

4.1108, DEVELOPMENT & APPLICATION OF QUANTITATIVE TISSUE CULTURE METHODS TO ENVIRONMENTAL PROBLEMS IN CHEMICAL TOXICOLOGY

B.H. PRINGLE, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Narragansett, Rhode Island* 02882

The development of a sensitive, reliable system for general toxicological studies involving chemical pollutants. The methods of quantitative tissue culture have been successfully applied to investigate nearly every conceivable process at the level of the cell. It is possible that such a system could be adapted for our needs, which would include the study of both fresh water and marine organisms.

A program was designed to evaluate the possible usefulness of quantitative cell culture for this particular purpose. The overall objectives include an evaluation of comparative toxicity, determination of the presence or absence of genetic effects, and the development of methods permitting the identification of 'no-threshold' chemicals.

Accomplishments of 1970: Initial efforts were started with a study of cadmium early in FY-1970. Full-time studies were initiated in January, 1970. Within this time, a titration end point for the toxicity of divalent cadmium to cultured mammalian cells has been established, and kinetic studies using four different concentrations of this metal are well underway. A reliable technique has been established for conducting kinetic studies and these are currently in progress.

Objectives for 1971: A. The immediate objectives for FY-1971 will include completion of the kinetic studies and the establishment of the kinetic curves. A quantitative model will then be constructed to describe these curves, and the model parameters interpreted in terms of cell structure and/or cell transport processes. B. Autoradiography techniques using electron microscopy will be investigated in an attempt to determine the amount of cadmium taken up by mammalian cells at 'threshold' doses. It is hoped that such studies will be instrumental in clarifying the physical meaning of the 'thresholds' observed in the kinetic studies. The feasibility of autoradiographic techniques with cadmium depends upon the availability of a suitable cadmium isotope, and to a lesser extent, the amount of cadmium taken up by the cells at 'threshold' doses. C. The toxicity of NTA and one additional trace element (mercury or arsenic) will be studied in the cell system and compared with data already available for rotenone and cadmium. It seems clear that comparative data for several classes of chemicals will be required before any evaluation of the technique can be made.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.1109, BEHAVIOR OF SPECIFIC HERBICIDES IN PLANTS AND SOILS

B.J. GOSSETT, Clemson University, Agricultural Experiment Sta., *Clemson, South Carolina* 29631 (SC00756)

OBJECTIVE: Determine the effects of climatic and edaphic factors on movement, persistence, and toxicity of herbicides in the soil.

APPROACH: The effects of edaphic and climatic conditions on the movement, persistence, and degradation of prometryne (2,4-bis(iso propylamino)-6-methylthio-s-triazine) and C-2059 (3-(n- trifluoromethylphenyl)-1,1-dimethylurea) will be investigated. Such factors as sunlight, soil moisture, temperature, pH, and organic matter content on the persistence and activity of these herbicides will be determined. Undisturbed soil profiles will be obtained by forcing a hollow cylinder into the soil to a depth of 3 feet. These soil columns treated with the two herbicides will be exposed to varying amounts and intensity of simulated rainfall. Bioassays will be conducted to determine the depth to which the herbicides moved in phytotoxic concentrations. Under field conditions, studies will be conducted on various soil types to determine the effect of soil incorporation and depth of incorporation on the performance of these herbicides.

PROGRESS: Under field conditions the performance of trifluralin and fluometuron was investigated as influenced by various spray volumes and incorporation into the soil at maximum uniformity and controlled depths. The rate of each herbicide used was 1/3x, 2/3x, and 1x of the suggested rate. With both herbicides, spray volumes near concentrate levels gave poorer weed control than conventional spray volumes. However, spray volumes as low as 2 gallons per acre gave weed control equal to that of conventional spray volumes. Better weed control was obtained with both herbicides when incorporated at maximum uniformity to a depth of 2 inches than at the 1- or 4-inch depths of incorporation. Incorporation of fluometuron at the 2-inch depth provided better weed control than when applied to the soil surface in the conventional manner and followed by irrigation. The response of cotton did not appear to be significantly influenced by any treatment, but statistical analysis are not complete.

SUPPORTED BY U.S. Dept. of Agriculture

4.1110, ECONOMIC EFFECTS OF PESTICIDE RESIDUES ON FOOD AND FEED PRODUCTS

L.D. MALPHRUS, Clemson University, Agricultural Experiment Sta., *Clemson, South Carolina* 29631 (SC00749)

OBJECTIVE: Study food and feed products with respect to the development of commercial marketing and processing techniques for the detection, removal and/or neutralization of pesticide residue effects. Estimate costs of alternative techniques for the commercial reduction of pesticide residues in food and feed products.

APPROACH: Reduce levels of toxaphene, guthion and parathion residues on harvested coastal bermuda grass and collards. Analyze sample data collected by Federal and State regulatory agencies of pesticide residues in selected food and feed products. Estimates would be made of the variability among lots of a product in the level of pesticide residues and the amount which would have to be removed from the market to comply with residue tolerances. Removal cost estimates would also be made. A cost analysis could be made of marketing or processing techniques identified or discovered under Objective 1 for the identification, reduction or neutralization of pesticide residues in food and feed products.

PROGRESS: No pesticide residue in excess of tolerances was found in 238 samples of cabbage collected in South Carolina retail stores during three seasons of 1966 in 8 cities. Fifty-four percent of the samples had measurable quantities of residues. Sixty three percent of 97 sweet potato samples collected in fall of 1966 had measurable quantities of pesticide residues within established tolerances and three samples had BHC for which no tolerance was established. Some breakdown and some loss of

parathion was noted when flour and bread containing it were heated to bread-baking temperatures. Fourteen to 17 percent of the parathion was unchanged by baking. Results were confirmed by a bioassay with German cockroaches in which toxicity was not increased but remaining parathion was accounted for.

SUPPORTED BY U.S. Dept. of Agriculture

4.1111, PESTICIDE RESIDUES IN PLANT AND ANIMAL PRODUCTS

J.K. REED, Clemson University, Agricultural Experiment Sta., *Clemson, South Carolina* 29631 (SC00827)

OBJECTIVE: Development, adaptation and standardization of chemical, instrumental and biological methods of residue analysis. (Methodology). Investigations on the behavior of chemicals as related to residues in agricultural commodities. (Behavior). Determination of residues and their metabolites in agricultural commodities and in their environment.

APPROACH: Biological assay, using Daphnia pulex in water, is used to verify analyses of pesticide residues in animal products, crops, soil, water, etc. Improvements are sought in methods of chemical analysis, chiefly in extraction, clean-up, and detection of the pesticides. Gas-liquid chromatography is being used extensively. The metabolism of trifluralin in fish is being studied in conjunction with the over-all area of retention, breakdown, and movement of pesticides in plants, soil, and water. The movement of DDT and trifluralin from soil into tobacco and soybean plants during growth is being followed to evaluate residues to be expected from growing crops on contaminated soil. Analyses of residues in samples of forage crops, vegetable crops, etc. are determined to facilitate securing labels for products used on minor crops where the volume of pesticide to be sold would not justify the cost to the responsible company.

PROGRESS: In a laboratory study fish accumulated DDT to a much higher level from water than from food even though the level in the food was much higher than in the water. DDT and malathion at sublethal levels caused a decrease in the total hemolymph protein and an increase in the number of non-protein amino acids found in the hemolymph of the crayfish, Cambarus bartoni Fabr. This may indicate interference with protein synthesis in some way. Monitoring of pesticide levels in wild deer populations has been continued for another year. To date only DDT and its metabolites have been positively identified in deer tissues but other unidentified chemicals are present at low levels. The level of DDT in turkeys penned on soil contaminated with DDT up to 40 lbs per acre is being followed to establish expected levels in turkeys reared on abandoned cotton fields where DDT has been heavily used.

4.1113, QUAIL MANAGEMENT ON FOREST AND ASSOCIATED LANDS IN WEST TENNESSEE

R.W. DIMMICK, Univ. of Tennessee, Agricultural Experiment Sta., *Knoxville, Tennessee* 37916 (TEN00003)

OBJECTIVE: Determine quail population levels in selected forest and associated land habitats. Determine timber and quail production with various land-management practices. Evaluate the economics of quail production systems.

APPROACH: Selected replicated sites will be described. Quail censuses will be taken. Populations will be related to site characteristics. Effects of selected management practices, such as burning and thinning, will be determined and related to quail and timber production. Economic analysis of timber and quail production will be performed.

PROGRESS: On the 2100-acre research area quail density was 83 coveys (1033 quail) in March 1969, and 73 coveys (1007 quail) in December 1969. These data indicate that a marked decline in quail density occurred during the summer period, the first decline in numbers since the study originated in 1966. A total of 177 nests were located during the 1969 nesting season. Success of nests was determined for 93 which contained eggs or egg fragments when found. Thirty-four (36.6%) were successful, 45 (48.4%) were destroyed, and 14 (15.0%) were deserted. Mean clutch size for 44 complete clutches was 12.6 eggs; however, only 75% of the eggs in 20 successful nests hatched. A total of 614 crops from quail collected on the research areas from December 1966 through March 1969 were examined. Identification of foods was completed, data were processed for IBM analysis, and analysis was completed. A thesis describing the food habits of quail is in final stages. A study of the behavior of wild quail in winter is in progress. Birds are now being trapped, marked with visible wing markers and/or radio transmitters, and released for observation. A total of 31 quail were collected during September 3 & 4 for analysis of pesticide residues.

SUPPORTED BY U.S. Dept. of Agriculture

4.1114, AGRICULTURAL CHEMICAL RESIDUES IN PLANT AND ANIMAL PRODUCTS

W.A. KRUEGER, Univ. of Tennessee, Agricultural Experiment Sta., *Knoxville, Tennessee* 37916 (TEN00049)

OBJECTIVE: Development, adaptation and standardization of chemical, instrumental and biological methods of residue analysis. (Methodology) Determination of residues and their metabolites in agricultural commodities and in their environment. (Dissipation)

APPROACH: Work will include development and adaptation of methods for the extraction and clean-up of samples of hay and animal products for the determination of heptachlor, heptachlor epoxide, DDT and other residues by means of the gas chromatograph. The fate of various residues during food processing, such as washing, cooking, and canning will be studied. Also, residues will be determined in agricultural products, including forage crops, vegetable crops, animal products and fruit crops to establish recommendations for safe usage, disappearance rates, and tolerance levels.

PROGRESS: Turnips were grown in control plots and plots treated with DDT and/or heptachlor epoxide. Samples were taken for residue analysis after spraying, at harvest, after washing and after blanching. Washing and blanching of turnip greens reduced TDE and DDT residues but did not affect DDE, heptachlor or heptachlor epoxide content. None of the processing treatments significantly affected root residues. Thermal processing effected a rise in TDE, but had no effect on DDE or DDT. The results of this study indicate that the processing treatments examined do not reduce insecticide residues to acceptable Food and Drug Administration standards.

SUPPORTED BY U.S. Dept. of Agriculture

4.1115, THE BIOLOGY AND CONTROL OF INSECTS AND MITES ATTACKING SMALL GRAINS

N.E. DANIELS, Southwestern Great Plains Ctr., *Bushland, Texas* 79012 (TEX01020)

Objective; Determine ecological and physiological factors which control small grain pests. Determine effectiveness of experimental insecticides on small grain pests. Determine influence of various farm practices on small grain insects and mites. Evaluate inheritance of greenbug resistance in small grains and the basis of resistance.

Approach: Studies of population densities in the oversummering and overwintering source areas of the greenbug and other selected species will be made. Research on the effects of temperature on reproduction, development and survival, development of winged forms and the existence of biotypes will be conducted. New experimental insecticides will be tested. Samples of treated crops will be analyzed for harmful residue. Evaluations on the effect of farm practices. The evaluation of greenbug resistant small grain sources.

4. PESTICIDES

Progress: Greenbugs infested both wheat and grain sorghum in 1966, 67 and 68 and were extremely heavy on grain sorghum during the summer of 1968. They were collected from field grain sorghum and reared alternately in the greenhouse, on wheat and grain sorghum. The adults of greenbugs collected from wheat were heavier than those collected from grain sorghum. Adult greenbugs reared outdoors were also heavier than those reared indoors. Grain sorghum yields were increased 5 percent by controlling, with parathion, a greenbug infestation of 22050 greenbugs per plant (164 greenbugs per gram of plant) while plants were in the boot stage and 31 inches tall. Plants 5 inches tall, that received no chemical treatment, died within 4 days after the population reached 2700 greenbugs per plant (900 greenbugs per gram of plant). Plants 19 inches tall, with no chemical treatment died within 14 days after a population peak of 13500 (337 greenbugs per gram of plant). Of 9 insecticides tested against the greenbug, in wheat, dimethoate and methyl parathion demonstrated the best control. Malathion gave good control of the false chinch bug in wheat and diethyl parathion satisfactorily controlled the insect in sugar beets. Efficient transmission of the virus Maize Dwarf Mosaic was achieved with the greenbug. Of 20 grain sorghum lines tested for greenbugs resistance none were found with significant resistance. After insecticidal soil treatments, endrin was the most prevalent in carrots the first year after treatment and dieldrin the second year.

SUPPORTED BY Texas State Government - Austin

4.1116, DEVELOP METHOD FOR QUANTITATIVELY CHARACTERIZING PESTICIDE DRIFT

L.F. BOUSE, Texas A & M University System, U.S.D.A. Agric. Eng. Res. Div., *College Station, Texas* 77843 (209-056-A126)

OBJECTIVE: Develop a standard method of making quantitative measurement of the driftability of a spray formulation or a spray formulation device.

APPROACH: Experimental measurement of spray driftability in the laboratory is considered the most practical method of quantitatively assessing spray materials and devices. A wind tunnel will be constructed with test section about 2' x 4' x 20'. A blower will provide air movement as desired. Controlled drop sizes will be provided by means of spinning disks. The movement of the droplets will be recorded by means of high speed photography. A device will be developed sufficiently simple and compact that any research agency, manufacturer, or regulatory agency can duplicate it.

PROGRESS: A low speed wind tunnel with controlled environmental facilities was constructed to study spray drift. This equipment permits precise measurements of factors affecting spray drift. The environmental factors controlled were air speed, temperature, humidity, and turbulence. The tunnel procedure will be used to compare the spray drift from the following carriers: 1) water, 2) diesel oil-in-water emulsion, 3) glycerol-water mixture, 4)cetyl alcohol-water mixture, 5) paraffin oil. Methods and techniques were developed for producing homogeneous herbicidal sprays by inducing harmonic disturbances in low- velocity jetstreams. Harmonic disturbances in the audiofrequency range applied to small low-velocity water jets formed by perforated orifice plates produced homogeneous sprays ranging from 100 to 450 microns drop diameter. This technique will be refined for utilization on prototype herbicide sprayers. Instrumentation and techniques were developed to measure electrostatic charges on houseflies. These techniques are being used to determine if insects respond to a pesticide on the basis of electrostatic charge on their bodies. Preliminary results indicate that respiration of an individual fly can be measured and that the amount of charge is related to length of time till death in a gas chamber. Further tests indicate that physical activity, food in the body, and the living versus death process can charge the electrical capacitance of the fly's body.

SUPPORTED BY U.S. Dept. of Agriculture

4.1117, AGRICULTURAL CHEMICAL RESIDUES IN PLANT AND ANIMAL PRODUCTS

H.W. DOROUGH, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (TEX02221)

OBJECTIVE: Development, adaptation and standardization of chemical, instrumental and biological methods of residue analysis. (Methodology) Investigations on the behavior of chemicals as related to residues in agricultural commodities. (Behavior) Determination of residues and their metabolities in agricultural commodities and in their environment. (Dissipation)

APPROACH: Determine and compare the effects of environmental conditions on the reproducibility of biological analysis of pesticide residues utilizing Musca domestica L., Determine methods of activation and detoxification of insecticides plant and animal tissues. Determine residual properties of pesticide.

PROGRESS: Insecticide residues were detected in the forage and seeds of soybeans planted in soils treated with chlordane and heptachlor. Heptachlor applied to soil at 6 lbs./a. 8 days prior to planting resulted in 0.9 ppm residues in the soil at planting time, 0.08 ppm in the plants at pod formation, and 0.11 ppm in mature seeds. Residues of approximately one-half these levels occurred when heptachlor was applied at 3 lbs./a. chlordane applied at 12 lbs/a. resulted in the following residue levels; soil, 0.8 ppm; plants, 0.07 ppm; and seeds, 0.04 ppm. Spraying sunflowers 2 or more times with malathion, methyl parathion, diazinon or endosulfan at a rate of 1 lb/a resulted in very low levels of residues in the seeds at harvest. Even when the last spray was applied 14 days before harvest, residues of endosulfan in the seeds were less than 0.2 ppm; for the other insecticides, the residues were only one-half to one-tenth this magnitude. The data indicate that residue problems would not prevent the use of these chemicals for the control of insect pests of sunflowers. Continued progress was made in defining the metabolic pathways of several carbamate insecticides in plant and animal systems. Temik and Furadan still appear to have excellent potential for becoming commercially available insecticides, although their use in some case may be highly restricted. Ensilage samples were taken from grain sorghum treated with several insecticides, some with ULV and low volume formulations, and some at different rates. Also, samples of seeds were taken from sunflower plants treated with insecticides not included in the residue tests reported above (para. 2).

4.1118, REDUCTION OF ADVERSE EFFECTS OF PESTICIDE RESIDUES ON FOOD PRODUCTS

A.R. HANKS, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (TEX02323)

OBJECTIVE: Study food and feed products with respect to the location and persistance of pesticides residues in market products.

APPROACH: Vegetables (including root, crops, squash, and tomatoes) contaminated with pesticides will be obtained from the Food and Drug District Laboratory in Dallas and from markets in areas where the crops are produced in the State. Penetration and distribution of the residues will be determined by sectioning the vegetables before and following storage under varying conditions of temperature, humidity, and time. Attempts will be made to remove the residues present in the surface of the vegetable by washing with aqueous solutions of surfactants at different temperatures.

PROGRESS: A total of 62 feeds were analyzed by gas chromatography for 14 chlorinated and 4 phosphate insecticides. 90% of the feeds analyzed contained measurable levels of chlorinated residues but no phosphate residues were detected. A total of 21 residues were at the 0.05 ppm level or greater. Contrary to the previous report (1968), the most commonly encountered pesticide was DDT (81% of all residues at or above 0.05 ppm). Dieldrin-previously the most common residue-was the second most commonly encountered residue; however, only one dieldrin residue was above 0.05 ppm. These results support previous findings indicating that there may exist a greater pesticide residue problem in animal feeds than in foods sold for direct human consumption. In view of established FDA residue tolerances and USDA recommended limitations on uses for treated crops (forages and grains), it would appear that a majority of the dairy feeds examined contain unacceptable amounts of pesticides. These residues are contributed, most probably, by the various feed components (corn, oats, sorghum, etc.).

SUPPORTED BY U.S. Dept. of Agriculture

4.1119, COMPARISON OF NUTRIENTS OF PEANUTS FROM SOILS WITHOUT AND WITH LINDANE TREATMENT

C.M. LYMAN, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (HN1-24(C))

OBJECTIVE: Determine whether lindane-treated soil changes amino acid, fatty acid, and B-vitamin content of raw and roasted peanuts as compared with nuts from untreated soil.

APPROACH: Analyze for: lindane residue, total lipids, fatty acids, total N, amino acids, and B-vitamins in raw and roasted peanuts prepared by methods approximating commercial practices. Samples represent crops grown on replicated untreated and lindane-treated soils for 2 years.

PROGRESS: Peanuts grown in experimental plots on soil treated with lindane as compared to those from untreated soil as control were analyzed, raw and roasted, for riboflavin, fatty acids of the lipids, protein, and the individual amino acids. This crop did not show a small increase in protein in peanuts grown on the lindane treated soil as indicated by the previous year. No differences were found in amino acids, fatty acids, and riboflavin of peanuts from treated and untreated soils.

SUPPORTED BY U.S. Dept. of Agriculture

4.1120, HARVEST-AID CHEMICAL RESIDUES IN COTTONSEED

C.S. MILLER, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (TEX01332)

OBJECTIVE: Develop suitable methods and techniques for determining amounts of harvest-aid chemicals or their metabolites that remain as residues in cottonseed or other parts of the cotton plant. Study the absorption, translocation and metabolism of defoliants and desiccants and develop suitable methods for identifying their metabolites. Investigate extraction and purification techniques for isolation of residues from large quantities of plant material.

APPROACH: Radioactive isotope-labeled cotton defoliants and desiccants, representing the principal chemical classes now in commercial use, will be applied to plants with bolls of different stages of maturity. The amount of the chemicals or their metabolites, by contact or translocation remaining on the lint, seed coat and in the seed meal oil will be assayed. The absorption, translocation and metabolism of commercial cotton defoliants will be studied by application of radioactive labeled materials to cotton plants, followed by their harvest at different intervals. Radioautograms of entire plants and chromatograms of extracts will be used.

PROGRESS: Arsenic acid residue studies were continued through obtaining 1100 pounds of cottonseed which contained 7 ppm arsenic. The seed were hulled, solvent extracted and the meal desolventized by the Oilseed Products Research Center for subsequent extraction and isolation purposes. About 242 pounds of cottonseed meal was extracted with water, screened, centrifuged, pH adjusted, centrifuged, reduced in volume, acetone precipitated, partitioned, volume reduced and stored in a freezer awaiting further purification. The arsenic was contained principally in two fractions, one of which was composed of 58% protein, was initially of axle-grease consistency and converted to an acetone powder.

SUPPORTED BY Texas State Government - Austin

4.1121, NUTRIENT COMPOSITION OF PEANUTS GROWN ON LINDANE TREATED SOIL

J.M. PRESCOTT, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (TEX01616)

OBJECTIVE: Plan and conduct investigations to determine the effects of lindane treatment of the soil on amino acid, fatty acid, and B-vitamin composition of raw and roasted peanuts.

APPROACH: Determine existing lindane level in plots of land to be used for investigations. Apply lindane to one-half of the plots, and leave one-half untreated to be control plots. Plant and produce for at least two successive years at least eight plots of a single variety of peanuts, using usual irrigation methods. Harvest and process peanuts produced, roasting one-half of treated and one-half of untreated peanuts. Conduct laboratory analyses, using chromatographic procedures, to determine lindane content in representative subsamples of all groups of roasted and unroasted peanuts from treated and untreated plots. Conduct laboratory analyses to determine component nutrients in those subsamples. Statistically analyze and evaluate data and results obtained.

PROGRESS: Analytical work on this project is complete and the data have been analyzed statistically. The final report is in preparation after which the project will be open for publication only.

SUPPORTED BY Texas State Government - Austin

4.1122, PESTICIDE ANALYSIS, COLLEGE STATION

R.A. STOKES, Texas A & M University System, U.S.D.A. Entomology Res. Div., *College Station, Texas* 77843 (00ENTM0305460100)

OBJECTIVE: Determine routes and rate of absorption, translocation, and breakdown or dissipation of systemic insecticides in cotton plants and soil.

APPROACH: Obtain information through analysis on rate of release of systemic insecticides from formulations into the soil, rate of adsorption on and desorption from soil, routes and rate of their absorption, translocation, and breakdown or dissipation in cotton plants, and identity and persistence of metabolites in the plants.

PROGRESS: A gas chromatographic procedure was developed for the analysis of dimethoate in aqueous samples and formulations. This method utilized a U-shaped glass column (2.5 ft. x 3 mm. i.d.) packed with 5% QF-1 on 60/80 mesh Gas Chrom Q and a flame photometric detector equipped with a 524-mmu interference filter for detecting phosphorus-containing compounds. A gas chromatographic procedure was developed for analyzing the four monoterpene components in a synthetic preparation of the boll weevil (Anthonomus grandis) sex pheromone with a single injection. The compounds were detected by hydrogen flame ionization after chromatography on a column loaded with 10% fluorosilicone (QF-1).

SUPPORTED BY U.S. Dept. of Agriculture

4.1123, INACTIVATION AND LOSS OF PESTICIDES FROM SOIL

A.R. SWOBODA, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (TEX02621)

OBJECTIVE: Determine inactivation and loss of pesticides from soil by: volatilization; retention and release; microbiological degradation; non-microbiological degradation; movement of water through and over soil for the purpose of identifying primary loss processes, relating these processes to soil properties, and predicting pesticide persistence.

APPROACH: Loss of pesticides from soils will be measured in the laboratory using vapor trapping devices. Retention and release of selected pesticides by soils will be studied using adsorption isotherms and column chromatography. The movement of pesticides through and across the soil will be studied in field experiments. Pesticides will be monitored in leaching and runoff waters.

PROGRESS: Work on the movement of DDT and Toxaphene in watersheds in Central Texas was continued. Due to the lack of runoff causing rainstorms during the past year few water were collected. Work was completed on the toxicity of arsenic to cotton and soybeans in two Texas soils. Arsenic was found to be very toxic to soybeans, especially on Amarillo fine sandy loam soil. Soil tests were investigated to determine toxic levels of arsenic. Arsenic was also found to become very soluble under flowed soil conditions. This reduced soil condition may cause arsenic to become more toxic to plants during rainy period during the growing season.

4.1124, PESTICIDE RESIDUE ANALYSIS, KERRVILLE
H.V. CLABORN, U.S. Dept. of Agriculture, Entomology Research Division, *Kerrville, Texas* 78028 (00ENTM0303461100)

OBJECTIVE: Determine the amount, persistence, and fate of residues of new insect control chemicals and their metabolites in animals, milk, poultry, and eggs.

APPROACH: Obtain information through analysis on rate of deposition, distribution, persistence, and fate in animal and poultry tissues of residues of chemicals applied for insect control and of their metabolites. Determine identity, amount, and fate of residues in milk and eggs. Analyze pesticide formulations to be used in experiments on insect control.

PROGRESS: Studies were made to determine the amount, distribution, and rate of disappearance of Shell Compound 4072 in eggs and the body tissues of chickens confined in houses treated with the insesticide for house fly control; of ronnel and its oxygen analog in the fat of cattle dipped one and two times in a 0.25% emulsion of ronnel, of CIBA 9491 and its oxygen analog in the body tissues of two calves sprayed with 0.25% and 1.0% emulsions of CIBA 9491; and of Dursban and its oxygen analog in the body tissues of cattle following multiple dippings in 0.025% emulsions of Dursban.

SUPPORTED BY U.S. Dept. of Agriculture

4.1125, METHODS OF ANALYSIS FOR PESTICIDES, KERRVILLE
H.V. CLABORN, U.S. Dept. of Agriculture, Livestock Insect Laboratory, *Kerrville, Texas* 78028 (00ENTM1103461100)

OBJECTIVE: Develop sensitive, accurate, specific methods of analysis for new insect control chemicals and for their residues and metabolites in animal and poultry tissues, milk, and eggs.

APPROACH: Study chemical and physical properties and reactions of new insect control chemicals and their metabolites to find specific measurable characteristics; develop quantitative analytical methods based on these characteristics. Develop efficient procedures for extraction and cleanup of residues for animal and poultry tissues, milk, and eggs preliminary to analysis.

PROGRESS: Sensitive methods were developed for determining CIBA 9491 and its oxygen analog in the body tissues of cattle and the oxygen analog of ronnel in the body tissues of cattle. A method was developed for determining the concentration of Dursban in dipping vats.

SUPPORTED BY U.S. Dept. of Agriculture

4.1126, REDUCTION OR ELIMINATION OF PESTICIDE RESIDUES ON FOOD AND FEED PRODUCTS
S.J. RITCHEY, Virginia Polytechnic Institute, Agricultural Experiment Sta., *Blacksburg, Virginia* 24061 (VA-0626106)

Objective: Study food and feed products with respect to location and persistence of pesticide residues in market products, effects of pesticide residue on quality characteristics.

Approach: The effects of processing techniques, cooking methods and length of storage on the persistence of certain pesticide residues in broilers will be studied. Tissue will be analyzed by recognized procedures of sampling, extraction and cleanup of samples and by gas chromatographic methods for analytical work at the time of slaughter and after periods of storage in the cold and before and after cooking. Muscles of the cooked broilers will be evaluated for flavor, odor, juiciness and tenderness. Chemical measurements of changes in fatty acid content will be done.

Progress: Data have been obtained on the effects of various cooking methods on residues of chlorinated pesticides in muscle tissues of chickens raised to market weight (8 weeks). The feed contained 10 ppm of aldrin, dieldrin, endrin, heptachlor and lindane. The 10 ppm level of endrin resulted in mortality of 75% of the birds. The various cooking methods were baking, frying and pressure cooking. Raw tissue was used as a control. In addition to the above methods, one bird from each pesticide treatment was further tested by baking sections of muscle for 30, 60, or 90 minutes.

SUPPORTED BY U.S. Dept. of Agriculture

4.1127, PREVENTING INSECT DAMAGE TO TOBACCO AND TOBACCO PRODUCTS IN MARKETING CHANNELS
D.P. CHILDS, U.S. Dept. of Agriculture, Market Quality Research Div., *Richmond, Virginia* 23240 (SP16)

OBJECTIVE: Investigate effect of environmental factors on physiology and reproduction of the cigarette beetle; evaluate insecticides for toxicity against adult cigarette beetles and determine residues in tobacco; and develop improved programs for controlling stored-tobacco insects.

APPROACH: Ecological studies to determine influence of environmental factors such as temperature, atmospheric humidity and moisture content of tobacco on the physiology, reproduction and behavior of the cigarette beetle. Compounds to be evaluated for residual, vapor, repellent and attractant action to adult cigarette beetles. Determine performance and nature of insecticide residues remaining in tobacco. Develop improved programs for insect prevention and control where tobacco is stored or processed.

PROGRESS: Movement of late stage larvae of the cigarette beetle from hogsheads of tobacco under semicontrolled warehouse conditions occurred twice. The larvae responded to a temperature gradient in tobacco located near the hogshead perimeter. All stages of the cigarette beetle remaining in the tobacco were killed by low temperatures. Temperatures near the center of tobacco hogsheads were below 40 F. for 90 days. The Bacillus disease of the cigarette beetle remains unidentified. Tests have shown mode of transmission to be mechanical. Gravid cigarette beetles were induced to oviposit on nonfood substances treated with ethanol extracts of attractant food materials. Mean number of eggs deposited on filter paper per female was 30.5 and viability was 91.2%. Efficiency of electric grid traps with BL lamp versus the standard trap to capture the cigarette beetle was approximately 3X in tobacco storages and 10X in a tobacco factory. About the same exposure time was required with 100 p.p.m. phosphine as with 500 p.p.m. to kill all stages of the cigarette beetle. Louvered warehouses were sealed satisfactorily for fumigation with phosphine when draped with tarps of 2-mil polyethylene. Overseas freight containers in sound condition were sufficiently gastight for fumigation of tobacco cases with phosphine. The fumigant was evolved from aluminum phosphide pellets used at 165 per 1,000 cubic feet and exposure was for 72 hours at tobacco temperatures above 60 F., and for 96 hours at tobacco temperatures below 60 F.

4.1128, THE BIOLOGY AND CONTROL OF INSECTS AND MITES ATTACKING STONE FRUITS
E.W. ANTHON, Washington State University, Agricultural Experiment Sta., *Pullman, Washington* 99163 (WNP01090)

OBJECTIVE: Determine the biology of new pests of stone fruits. Determine the most economical control measures of pests attacking stone fruits; also, pests that are resistant to standard insecticides now in use. Spray and collect fruit for residue analysis.

APPROACH: Explore the specific use of insecticides which would promote the use of natural biological agents. Test various insecticides for controlling stone fruit pests and continue biological studies of temperatures in relation to San Jose scale crawler stage.

PROGRESS: The peach twig borer was successfully reared on wheat germ diet through two generations under laboratory conditions. The adding of more alphacel to the diet and a germicidal lamp treatment to the freshly made medium assisted in drying the media enough to allow the larvae to move about freely. Wheast (a yeast cultured on cottage cheese whey) when added to the diet made it more acceptable to the neonatal larvae. The neonatal larvae were induced to eat the medium when confined in tightly lidded plastic jelly cups placed in complete darkness. Integrated mite control studies on prunes indicated that an early prebloom supplemented by a mid-season mite spray provides sound and economical control. Laboratory and field testing in-

dicated that Plictron, omite, TH-467-I Hoc. 2960, Fundal and Humble plus Collier oil plus omite provided good control of mites on stone fruits. The materials most promising for aphid control were Fundal, American Cy. 72613, Stauffer R 15552 - 15792, Baygon and Azodrin.

SUPPORTED BY Washington State Government - Olympia

4.1129, PHYSICAL METHODS OF IDENTIFICATION AND DETERMINATION OF PESTICIDES AND THEIR DEGRADATION PRODUCTS

D.R. COAHRAN, Washington State University, Agricultural Experiment Sta., *Pullman, Washington* 99163 (WNP01793)

Objective: Develop improved methods for the separation, identification and determination of pesticides and their degradation products.

Approach: Initial work will be on gas chromatography, with emphasis on selective detection methods which give qualitative as well as quantitative information on the composition of the material being chromatographed. The use of such detectors will greatly simplify the identification of materials resolved by gas chromatography. The detectors under consideration include electron capture, hydrogen flame, mass spectrometer, and spectrometric glow discharge.

Progress: Preliminary work was done on a radio-frequency glow- discharge gas chromatographic detector utilizing the spectrum of the light produced by the discharge to identify the material detected. Progress was slow, however, and the project was dropped when Cooke published the design of a detector operating on the same principle. Work was done on a swept-voltage electron capture detector for gas chromatography. Such a detector should give information about the structure of the compound being detected. Initial experiments were not successful, due to the very slow response of available electron capture detectors to voltage change. This idea is not being pursued at present, but work will be resumed under another project when fast-responding detectors become available. A phosphorus-sensitive Gas Chromatographic detector of greatly increased stability was developed and the design was published. An improved version is now commercially available. This detector has been of great value in the analysis of organo-phosphate pesticide residues.

SUPPORTED BY U.S. Dept. of Agriculture

4.1130, METHODS OF ANALYSIS FOR PESTICIDES, YAKIMA

L.M. MCDONOUGH, U.S. Dept. of Agriculture, Entomology Research Division, *Yakima, Washington* 98902 (00ENTM1104500809)

OBJECTIVE: Develop sensitive, accurate, specific methods of analysis for new insect control chemicals and for their residues and metabolites or breakdown products in agricultural crops, animal tissues, and soils.

APPROACH: Study chemical and physical properties and reactions of new insect control chemicals and their metabolites to find specific measurable characteristics; develop quantitative analytical methods based on these characteristics. Develop efficient procedures for extraction and cleanup of residues from plant and animal tissues and soils preparatory for analysis.

PROGRESS: An analytical method was developed for the determination of residues of carbofuran, its hydroxy- and its keto-metabolites by the preparation of a trichloroacetate derivative and subsequent analysis by EC-GLC. It has been applied to tomatoes, tomato foliage, soil, potatoes, lettuce, and cucumbers.

SUPPORTED BY U.S. Dept. of Agriculture

4.1131, INTERFERING SOIL CONSTITUENTS IN DETERMINATION OF PESTICIDE RESIDUES IN SOIL AND WATER

C.W. CARLSON, Univ. of Wisconsin, Agricultural Experiment Sta., *Madison, Wisconsin* (SWCW8-BELT-19)

OBJECTIVE: Determine the most effective method for extracting and purifying pesticides from soil types and runoff and drainage waters and develop accurate analytical procedures for estimating pesticide concentrations.

APPROACH: Conduct investigation bases designed to determine accurate analytical procedures for the determination of extremely small concentrations of organic pesticide residues in soils and runoff and drainage water. All soil components which interfere with the final analytical determination will be completely evaluated and the methods and necessity for removal investigated. Analytical procedures which will completely extract pesticides residues from different soil systems and waters will be developed; interferring substances from soil extracts will be identified and methods for effectively removing them developed.

PROGRESS:

SUPPORTED BY U.S. Dept. of Agriculture

4.1132, THE BIONOMICS AND CONTROL OF INSECTS ATTACKING VEGETABLE CROPS

J.L. LIBBY, Univ. of Wisconsin, Agricultural Experiment Sta., *Madison, Wisconsin* (WIS01605)

OBJECTIVE: Study the bionomics of and develop control programs for vegetable crops insects. Determine insect resistance to control measures and the effects of control materials on the environment.

APPROACH: Determine vegetable crops pest species and populations, their life cycles and habits. Utilize chemical and biological agents to develop control programs for pest species in field studies. Determine insect resistance to control agents in field studies. Analyze plant and soil samples by gas chromatography to determine insecticide residue levels and any environmental contamination.

PROGRESS: Chemical and biological control materials were applied to aid in determining effective controls for cabbage worms, root maggots, leafhoppers and flea beetles on cabbage, beans, rutabaga and potatoes. Phytotoxicity studies were conducted in all these plots. Bacillus thuringiensis Berliner will provide an alternative to chemical control of cabbage looper, Trichoplusia ni Hubner only when used at relatively high dosages at regular weekly intervals. Phytotoxicity studies showed the soil applied systemics phorate and disyston to have an adverse effect upon the production of Norland variety potatoes at 3 lbs. and 6 lbs. active ingredient per acre. Three pounds is the generally recommended dosage for commercial application to potatoes.

SUPPORTED BY U.S. Dept. of Agriculture

4.1133, ENVIRONMENTAL IMPLICATIONS OF PESTICIDE USAGE

E.P. LICHTENSTEIN, Univ. of Wisconsin, Agricultural Experiment Sta., *Madison, Wisconsin* (WIS01387)

OBJECTIVE: Devise and improve sampling, extraction, and analytical techniques to facilitate quantitation of pesticide residues and degradation products in soils, plants, and animals. Examine the action, persistence, degradation, and translocation of selected biocides and their metabolites in plants, animals, and microorganisms. Describe the evaluate biocide cycling through the soil and water environments, particularly in reference to food chains.

APPROACH: Strictly controlled laboratory tests, accompanied by field tests at the U.W. farms are being conducted. Generally, attempts will be made to further answer questions as the reasons for observed effects. Studies on a subcellular level will be conducted.

PROGRESS: Polychlorinated biphenyl plasticizers were found to synergize the toxicity of several insecticides. Their interference in analyses of insecticides was also demonstrated. Enzyme systems were isolated from subcellular plant components that epoxidize aldrin to dieldrin. Contrary to animal enzymes, those from plants were specific for aldrin. A ten year field study showed that the 'persistent' insecticides, aldrin and heptachlor, disappeared (although relatively slowly) from soils through metabolism into non-toxic compounds and through volatilization. Effects of various insecticides on soil fungi were studied. Interactions between insecticides and aspirin on human cells in tissue culture were investigated and the effects on synthesis of DNA, RNA and protein were determined. Aspirin showed effects similar to those that were observed with the insecticides. Fate and metabolism of the organophosphorus insecticide Guthion was studied under both field and laboratory conditions.

SUPPORTED BY U.S. Dept. of Agriculture

4.1134, STUDY OF THRIPS TABACI, ITS BIOLOGY AND ECOLOGY, A VIRUS VECTOR ON TOBACCO

B. TODOROVSKI, Inst. of Tobacco, *Prilep, Yugoslavia*
(PL480E30ENT9)

OBJECTIVE: Determine biology and ecology of tobacco thrips, its effect on yield and on virus transmission.

APPROACH: Study life history and development of tobacco thrips; effects of environmental factors on movement and population fluctuations; differences in varietal susceptibility to thrips injury and virus transmission, and characteristics of direct injury and virus- vector relationships. Develop methods for control and determine pesticide residues in tobacco.

PROGRESS: Continuing yellow pan surveys indicated that the highest population of onion thrips appeared late in August 1969 as compared to July 1968. Onion thrips' populations varied considerably on different varieties of tobacco. Certain pesticides control thrips well on some tobacco varieties but not on others. Biochemical research to determine the reason for these differences in pesticide efficiency on certain varieties and not others is being initiated. The LV3 virus was purified by ultracentrifugation, and electron micrographs of the material will be made to determine form and particle size. It was noted that tobacco from LV3 virus infected plants is of low quality. This was attributed to the decrease in soluble carbohydrates and polyphenols in the tobacco leaves which resulted in a weak taste.

5.0001, STRONTIUM-90 LEVELS ON THE DIETS AND BONES OF CHILDREN
D. BENINSON, Comision Nac. De Energia Atom., *Buenos Aires, Argentina* (AT(30-1))

The objective of the project is the determination of parameters governing the contamination of bone as a function of age and the levels of strontium-90 in the diet.

Turnovers of strontium have been determined independently of Sr to Ca discrimination factors by placing emphasis on specific activity measurements.

Radium-226 measurements have been carried out for comparison of its behavior with that of strontium. It is proposed to complete the project with one more year of work at about the same intensity, improving the reliability of the estimates of metabolic parameters.

Results: From determination of Sr-90/Sr specific activity and strontium to calcium ratios in bones and diets, bone turnover rates and strontium to calcium discrimination factors have been estimated for several age groups, but some of the estimates should be qualified by substantial uncertainties.

SUPPORTED BY U.S. Atomic Energy Commission

5.0002, DETERMINATION OF U-235 ENRICHMENT IN UNIRRADIATED URANIUM BEARING STREAMS
N. BACHVAROV, Bulgarian Acad. of Sciences, *Sofia, Bulgaria*

Non-destructive analytical techniques are urgently needed for the accurate determination of the fissile content of process streams, analytical samples and, in particular, for scrap material. The existence of such techniques would make a major contribution in the ability of promptly detecting diversion of fissile material from the fuel cycle.

In anticipating the particular problems of safeguarding enrichment facilities we are trying to develop different methods and techniques to cope with the safeguard task for this part of the fuel cycle. In particular, attention is being focused on development of techniques to determine the enrichment in the flow of UF6.

The objective of present work is to investigate prospective instrument techniques of x-ray fluoresecence and gamma measurement for analysis of U-235 in U-bearing streams, using ratio of intensities of 185 KeV gamma rays from U-235 and K x-rays from total uranium. Spectrometry will utilize semiconductor system with 4000 channel analyzer DIDAC.

The programme of work shall include optimizing the geometry of the detector(s) and assessing a number of possible radiation sources such as Co-57 and Se-75 required for K x-ray fluorescence excitations; and studying the accuracy of the method.

Test will be made initially on UF4 sample. Subsequently, the method will be further developed and tested on UF6 samples.

5.0003, METEOROLOGY FOR NUCLEAR TESTING
UNKNOWN, Meteorology Research Inc., *Altadena, California* 91001 (011624)

To develop an atmospheric model of diffusion over large distances: (a) Design and execute a cooperative experiment with NASA consisting of a field program measuring relative spread of clusters (2 to 4) of tetrooms as a function of travel time and meteorological conditions; (b) Processing of the data on cluster spread; (c) Preliminary development of an advanced model for large cloud quasi instantaneous source diffusion in simple two dimensional shear flows using results of the field program as input parameters; (d) Recommend for further testing and development of the model.

The field program has been completed in so far as funds have been available and the data are in hand. Interpretation in terms of field parameters and first effort towards developing the model are essentially complete. The model has not been tested and its suitability has not been determined.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

5.0004, THE FATE OF TRITIUM RELEASED BY NATURAL GAS STIMULATION AND STORAGE EXPERIMENTS USING NUCLEAR DETONATIONS
L.R. ANSPAUGH, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

An important area of the Peaceful Uses of Nuclear Explosives program over the next several years will be in the areas of the stimulation of natural gas production and the creation of reservoirs for the storage of natural gas. Both activities will produce large amounts of tritium which will present one of the greatest potential hazards. Two such events, Gasbuggy and Rulison, have already been detonated, and there will possibly be one additional experiment per year over the next five years with the goal of achieving actual commercial usage at the end of the five-year period.

The primary objectives of this program would be to determine the movement of tritium through the biosphere and to assess the ultimate exposure to man from the release of tritium into diverse ecosystems. To accomplish our objectives, we intend to follow the movement of tritium through different trophic levels of exposed ecosystems and to determine at each point the relative partitioning of tritium between organic matter and unbound water. One of the major objectives is to carefully evaluate possible isotopic fractionation mechanisms between trophic levels and between organic matter and unbound water. Such isotopic fractionation mechanisms have been observed for both deuterium and tritium although the possible significance of such mechanisms remains to be adequately evaluated.

Results: This is a proposed new project and no experimental work has been done. An evaluation of the potential biological hazards associated with Project Rulison has been made and published.

5. RADIATION

SUPPORTED BY U.S. Atomic Energy Commission

5.0005, STUDIES OF DEPOSITION AND REDISTRIBUTION OF DEBRIS FROM SPECIFIC NUCLEAR EVENTS
L.R. ANSPAUGH, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

The broad objectives of this program are to document the amounts of radioactivity released by specific nuclear events, and to study the transport, the deposition, and the redistribution of the debris. Physical methods of measurement will be used primarily. Biological studies may be done if deemed appropriate, but only when the physical parameters are measured first or simultaneously. Field instrumentation stations have been developed and will be improved upon as the requirements are established. These stations will be used in a network that will furnish radioactivity (specific radionuclides) concentration in the air and ground deposition as a function of time. Appropriate micrometeorology parameters may be measured. Provisions have been made for collecting as a function of time, samples that may be used in establishing fallout particle characteristics. The measurements from these stations will aid the refinement of predictive transport and deposition models.

Field studies were conducted on the Plowshare Cratering experiment, 'Schooner', at the Nevada Test Site. Redistribution over a 1000 hour period following the experiment was documented. This was the first time quantitative studies have been carried out on a Plowshare experiment, with the resultant verification of significant redistribution. Over 20 different radionuclides were studied and quantitated.

5.0006, RADIOECOLOGY OF DEBRIS RADIONUCLIDES AT INTERMEDIATE DISTANCES FROM NUCLEAR CRATERING EVENTS
R.J. GRABSKE, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

The objective of this program is to evaluate the movements in the local ecosystems of radionuclides produced by nuclear cratering events and deposited at distances between 30 and 150 miles from the detonation site. Significant results are to be expected from such a study for two reasons. First, this distance range includes these areas of land outside the Nevada Test Site that are most likely to receive fallout from the test. Second, any debris falling in these areas may more closely resemble in particle size and chemistry the debris that could fall in distant populated areas than debris falling close to the test site.

The measurements proposed include analyses of gamma-emitting radionuclides in the local soils, water, plants, and animals. These materials will be rechecked periodically in areas showing the evidence of fallout for several months after the event or until the radiation levels fall too low for adequate monitoring. These field studies will be supplemented by studies of radionuclide uptake in common food plants grown in the laboratory in radioactive soils collected in Nevada.

Results: Following the Schooner event a survey was made to the north and east of the detonation. Soil, plant, water and wildlife samples were collected. All samples were analyzed for gamma radioactivity. At Livermore a number of species of plants were grown in contaminated Nevada soil to determine the soil-to-plant transfer coefficients for W-181, the major radionuclide.

SUPPORTED BY U.S. Atomic Energy Commission

5.0007, CHARACTERIZATION OF RADIOACTIVE PARTICLES PRODUCED BY NUCLEAR DETONATION
R.E. HEFT, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

Objective; To determine how the individual radionuclides produced by nuclear detonation are distributed according to particle type and particle size.

Reason; The mode of interaction of the radionuclides with the biosphere depends on the physical and chemical properties of the particles population. Thus, a radionuclide which is volume distributed in 500 micron particles has an entirely different biological interaction potential than one which is surface distributed on 10 micron particles. In order to predict the potential biological effects of a given nuclear detonation, it is necessary to be able to predict radionuclide distribution in the particle population.

Procedure; Early time, close-in, aerial filter and fallout samples from a specific nuclear detonation are systematically separated according to particle type and size. The separated fractions are subjected to high resolution gamma spectrometry in order to determine individual radionuclide abundance, and hence radionuclide distribution.

Test Objects and Agents: Close-in particle samples.

Results; Radionuclide distribution for cratering detonations can be understood in terms of a two-stage condensation process. The radioactive plasma produced by the detonation is initially completely contained by a molten rock cavity liner. Depending on a Henry's law interaction, each radionuclide condenses to some extent in the molten liner. When the liner ruptures, venting occurs and the uncondensed radionuclides escape from the temperature cavity and rapidly deposit on the surface of particles produced in the overburden by the shock wave.

SUPPORTED BY U.S. Atomic Energy Commission

5.0008, ECOLOGICAL STUDIES OF RADIONUCLIDES IN ECOSYSTEMS AT NUCLEAR DETONATION SITES
J.J. KORANDA, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

This program is concerned with the distribution and movement of long-lived radionuclides, especially tritium, in ecological and biological systems occurring at nuclear detonation sites. Comparative ecological studies are conducted elsewhere to provide specific information when it is not available. The movement of tritium through soil, plants and animals of a single ecosystem has been studied in the desert environment of the Nevada Test Site, and in the tropical rainforest in Puerto Rico. Current studies are being conducted in other environments, and with agricultural plants as well as natural vegetation.

Continuing studies will be concerned with the half-time of tritium from either a liquid or vaporous exposure in selected plant species, in soils, and in diverse ecosystems. These tracer studies will be conducted at Livermore, NTS, and in other areas of the U.S. Long-term studies will be continued at Sedan crater where the emphasis will be upon half-residence time measurements, and physiological studies in plants and animals.

Results: Research conducted at Sedan crater in the Nevada Test Site has indicated that the half-residence time of tritium in the ejecta or soil around the crater is of the order of 15-18 months. Evaporation, transpiration by plants, and losses to deeper soil water compartments accounts for this loss rate. Comparative data obtained in the tropical rainforest in Puerto Rico show that the half-residence time of tritium in that environment is considerably shorter, and on the order of 77 days for a watershed.

SUPPORTED BY U.S. Atomic Energy Commission

5.0009, ANALYSIS OF RADIONUCLIDE TRANSPORT AND DEPOSITION FOR PREDICTION OF UPTAKE AND DOSES FROM RELEASE OF RADIONUCLIDES
Y.C. NG, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

This analysis of the transport and deposition of radionuclides is a main category of a predictive program designed to provide the following kinds of information: (1) guidance for radiation safety analysis of proposed applications involving nuclear energy, (2) guidance for documentation of the release of radionuclides to the biosphere, and (3) guidance for design in applications involving nuclear energy. This portion of the prediction program deals specifically with the transport of radionuclides from the source of their production estimates and biological uptake relationships to arrive at estimates of the burden and dosage to man. The overall approach is described in a series of reports. The fallout deposition by washout or rainout, provide new information that will be used to update the atmospheric transport phase of our predictive approach.

Results; Fallout depositions that were measured subsequent to Project Schooner of the Plowshare cratering program have been examined and correlated with the radionuclide concentrations that were reported in the milk and feed of dairy cattle following the event, and the implications of these results of a proposed Plowshare cratering experiment have been discussed.

SUPPORTED BY U.S. Atomic Energy Commission

5.0010, THE STUDY OF THE LIFE HISTORY OF RADIONUCLIDES RELEASED INTO A MARINE AND TERRESTRIAL ECOSYSTEM AT THE SITE OF A SMALL BOILING-WATER REACTOR

P.L. PHELPS, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

Primary emphasis will be placed on following the movement of tritium through both the marine and terrestrial environments. The measurement of deposition velocity, residence time in the biota, and quantitative relationships will be studied. These measurements will be related to atmospheric and surface conditions. Transport mechanisms and concentration in biota of other radionuclides will be included in the program. Data derived from these studies will be applicable to model development for future reactor siting.

SUPPORTED BY U.S. Atomic Energy Commission

5.0011, BIOLOGICAL AVAILABILITY TO DAIRY PRODUCTS OF MAN-MADE RADIONUCLIDES

G.D. POTTER, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

This project has been designed to determine the 'biological availability' of metabolism and transport of orally administered radionuclides in the lactating dairy cow and in the calf. Special emphasis has been placed on the secretion of these nuclides in milk and their deposition in tissues. Since a large portion of the diet in this country consists of milk, milk products and beef it is important to determine and understand mechanisms responsible for the secretion of radionuclides into milk and their deposition in tissues as potential pathways in the diet of man. Data obtained from such studies should single out those radionuclides which could present major problems and may also suggest possible countermeasures for the reduction or removal of these radionuclides from the diet of man. The radioisotopes are administered orally to lactating cows or calves as single radioisotopes, as mixtures, or in the form of debris from nuclear events (specifically Plowshare nuclear cratering events). Analysis of the total milk, urine and fecal output of the cows is carried out using sodium iodide detectors for single isotope experiments and lithium-drifted germanium detectors (Ge(Li)) for complex mixtures and debris studies. Similar methods are used for tissue distribution studies in the calves. Uptake and disappearance curves are constructed for individual radionuclides in milk, urine, feces, plasma and erythrocytes. These studies have been extended to Beta-emitting radionuclides including tritium.

Results: Studies on approximately 35 radionuclides have been completed on lactating cows, and about 12 radionuclides have been run in calves. In addition, studies have been completed on cows fed debris from several Plowshare nuclear cratering events. Portions of this material have been submitted and the remainder is being prepared for publication.

5.0012, DISTRIBUTION AND INTERRELATIONSHIP OF ELEMENTS IN BIOLOGICAL SYSTEMS

G.V. ALEXANDER, Univ. of California, Lab. of Nucl. Med. Rad. Biol., *Los Angeles, California* 90024 (AT(04-1)GEN-12)

The primary goal of this project is to determine the distribution and interrelationships of the elements present in biological systems. Of fundamental importance to this goal is the development of efficient analytical methods which will produce accurate results. To meet these requirements an emission spectrometric analytical system has been developed which requires little sample preparation, is simple to operate and is capable of simultaneously determining some 25 elements commonly observed in plant and animal tissues.

Frequently very little is known of the element pattern that would permit a differentiation between a diseased state, radiation damage, ageing and the 'normal' state. The application of multielement analysis and the use of the resulting element interrelationships adds a new and important dimension to this type of differentiation.

Results: During the past year over 11,000 plant samples have been analysed . For the most part these samples are related to the studies of element translocation in desert plants of the Nevada Test Site Region. The cycling of radionuclides and stable elements in areas under study at the Nevada Test Site is being investigated. Related problems such as species variability in accumulation of radionuclides and other elements are also under investigation.

5.0013, INFLUENCE OF SOIL HEATING ON THE GROWTH AND ELEMENTAL COMPOSITION OF BEAN PLANTS

H. NISHITA, Univ. of California, Lab. of Nucl. Med. Rad. Biol., *Los Angeles, California* 90024 (AT(04-1)GEN-12)

The soil in the immediate vicinity of a nuclear detonation may not only be contaminated with radionuclides, but is exposed to heat ranging in temperature well above that causing vaporization down to ambient level. One of the unknown factors arising from these detonations is the influence of soil heating on the availability of the soluble radionuclides in the soil-plant-animal cycle.

Another interesting aspect is the effect of soil heating on the availability of the essential nutrient and the non-essential elements to plants. It is necessary to know the effects of these factors in determining the relationship between ionizing radiation and plant growth in areas exposed to nuclear detonations. Thus, the objective of this project is to determine the growth and elemental composition of plants as a result of soil heating. Experiments are being conducted in the greenhouse using beans as test plants.

Results: The effect of soil heating on the following soil properties were examined: weight loss, particle size distribution, pH, organic matter content, total N, cation exchange capacity, electrical conductivity of saturation extract, and seven NH4OAc extractable cations. The plant leaves were analyzed for 2 radionuclides and 19 stable nuclides in one experiment. The determination of the extractability of different elements in heated soils is in progress.

SUPPORTED BY U.S. Atomic Energy Commission

5.0014, PHYSIOLOGICAL ECOLOGY STUDIES OF DESERT VEGETATION

A. WALLACE, Univ. of California, Lab. of Nucl. Med. Rad. Biol., *Los Angeles, California* 90024 (AT(04-1)GEN-12)

Life histories of major perennial shrub species occurring in the Nevada Test Site are being studied. Phenological records including dates for vegetative growth, flowering, fruiting, leaf fall, dormancy are being kept. Age structure, plant size and weight, and annual productivity are being determined. Annual productivity is also being determined for herbaceous plants. Special studies are being undertaken to determine rates of growth and standing biomass of roots. Mineral nutrients in plant parts are being determined as is similar data for other biotic components and that of the soil for mineral cycling evalution. Special emphasis thus far has been placed on nitrogen and phosphorous. Many of the plant species have been vegetatively propagated and these materials have been used for glass-house studies and effects of environmental variables on those species. Air and soil temperatures have been studied in some detail and important interactions on some shrub species have been determined. Responses of plants to soil pH and salinity are being investigated to explore ecological aspects of the distribution of these species in nature. Effects of these factors and rates of photosynthesis and water use are being studied. It is expected that these studies are to serve as guide lines and integral parts of additional studies concerning effects of radiation on plants and on cycling of radionuclides in desert ecosystems.

Results: After 5 years of gamma irradiation of a plot at the Nevada Test Site wth a 33,000 curie Co60 source to give a cumulative exposure of about 30kR, only one of the plant species, 'Ephedra nevadensis', seems to have been affected. In 1969 this species essentially failed to flower and very few fruits were set relative to plants in non irradiated areas. Progress has been made on all aspects of the project.

5.0015, RESEARCH ON FAULTS AND FAULT ACTIVITY FOR LAND-USE PLANNING

M.G. BONILLA, U.S. Dept. of the Interior, Geological Survey, *Menlo Park, California* 94025

States to which project pertains: Worldwide in scope.

To review and summarize the historic record regarding those aspects of fault activity which are especially important in land-use planning, with particular emphasis on nuclear power reactor siting.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

5.0016, GEOCHEMISTRY STUDIES WITH STABLE AND RADIOACTIVE SPECIES

S. EPSTEIN, Calif. Inst. of Technology, Graduate School, *Pasadena, California* 91109 (AT(04-3)-767,07)

The evolution of lead influx into our society will be examined by making lead analyses of artifacts and of ores from old civilizations and by examining early metallurgical processes in which lead was involved.

Natural suites of zircons of known crystal radiation damage and of known U-Th-Pb content will be exposed to high temperature and pressure fluids simulating hydrothermal conditions within the earth's crust to permit interpretation of natural hydrothermal conditions to which the zircon has been exposed during its geologic processes.

The problem of interpreting isotope data of lead in feldspars from ancient granites will be attacked by extracting lead from different parts of the feldspars. These techniques should provide information regarding the mobility and redistribution of the lead in the feldspar crystals during modifying geologic processes.

Additional zircon samples from Precambrian basement rocks underlying the Colorado Plateau will be analyzed for the high uranium anomaly to ascertain the history of uranium distribution in the area. Basement rock samples brought up from deep oil wells and by volcanic activity will be the most promising source of samples at this time.

Improved mass spectrometer techniques in measuring small quantities of lead for its isotopic composition permit investigation of single microscopic crystals of U-Th-containing minerals, provided it is possible to eliminate the lead contamination and complex chemistry in preparing the lead for the mass spectrometer.

A survey of the Si30/Si28 ratio of the various natural materials is to be made to establish the possible existence of some systematic pattern in the variations, similar to that observed for the O18/O16 ratio in silicate rocks and minerals.

The establishment of the D/H ratio partition between some hydrous minerals should permit a better understanding of the D/H record in some hydrous minerals. D/H analyses should provide a possible 'temperature' of their formation and an isotopic composition of 'primary igneous water'. The D/H ratio may tell us whether the ocean formed all at once in the early history of the earth or gradually accumulated with continuous degassing of the earth. As a by-product of these investigations, we may be able to learn whether the early forms of life on earth originated in fresh waters or marine waters. (Text Abridged)

5.0017, CHEMICAL REACTIONS INDUCED BY ULTRAVIOLET AND IONIZING RADIATION

G.S. HAMMOND, Calif. Inst. of Technology, Graduate School, *Pasadena, California* 91109

Air Force flight operations involve potential exposure of materials and personnel to harmful radiation. Means are required to inhibit radiation induced damage in order to assure mission completion. This research reveals basic chemical and physical effects of radiation at the molecular level by which energy is dissipated. Specific guidance is afforded design, selection, and synthesis of new materials of increased radiation resistance. Special research emphasis is afforded studies of the detailed kinetics and mechanisms of chemical change induced by high energy radiation - alpha particles, gamma rays, and protons. Prototype studies will be made with chemical systems already well characterized photochemically - using less energetic photons of light radiation. High energy radiation produces many kinds of short-lived chemical species - ions, free radicals, and molecular excited states. These species are precusors of eventual, stable chemical products. Use of systems of well defined photochemistry permits identification of those parts in the radiochemical systems following photochemical reaction pathways. The study of the residual chemistry following other paths is much simplified. Corrollary photochemical studies are designed to reveal systematic relationships between molecular structure and chemical reactivity.

5.0019, A STUDY OF LASER DAMAGE TO BIOLOGICAL MATERIALS

F.S. BARNES, Univ. of Colorado, School of Engineering, *Boulder, Colorado* 80302

This coming year, it is proposed to do a detailed study of the generation of acoustic waves by means of a Q-switched laser and their damage to biological materials. In particular, we expect to make measurements of a peak pressure and peak pressure gradients of acoustic waves generated by a Q-switched laser as a function of the geometry absorbed laser beam and the power input. Additionally, we expect to measure the characteristics of reflected and transmitted acoustic waves from soft tissue. The objective is to obtain detailed information in the interaction between acoustic waves and biological material including power absorbed, the velocity of propagation, the pressure, and the peak pressure gradients. Additionally, we expect to determine the peak pressure or peak pressure gradients for threshold damage to biological materials.

5.0020, CENTRAL NEVADA GEOLOGIC INVESTIGATIONS

E.B. EKREN, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

State(s) to which the work listed herein pertains: Nevada.

The first and principal objective of this project was to determine the suitability of Central Nevada as a supplemental test site for underground nuclear testing. Geologic studies, deep drilling, and one nuclear underground test have demonstrated this suitability. Current objectives are to complete mapping eight 15' quadrangles and specific parts of two others, continue to upgrade our knowledge of stratigraphy and structure in order to provide precise data when they are needed by the AEC, AEC contractors and cooperative agencies. As long as the AEC is involved in Central Nevada, we will continue to refine our geologic knowledge. We will publish quadrangle maps at scales of 1:48,000, write intermittent administrative reports for the AEC, and depending on the continuation of the area as a test site, will start a final report in 1971 or 1972.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

5.0021, PLOWSHARE SPECIAL STUDIES
F.W. STEAD, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

Specialized geologic and hydrologic studies by the Geological Survey will provide data for evaluation both of technical feasibility and of public safety of proposed Plowshare nuclear detonations. Recommendations and suggestions to AEC will be made outlining further studies and tests needed to resolve problems in using nuclear explosives effectively and safely in various environments.

Proposed peaceful applications of nuclear explosives are sponsored and primarily funded by industry (Project Sloop--the in situ leaching of an oxidized copper ore body; Project Rio Blanco--stimulation of natural gas production from low permeability reservoir; Project Utah--shattering of oil shale preparatory to in situ retorting), and by government (Project Aquarius--water management in the State of Arizona). Within the next year or so, under the Non-Proliferation Treaty (NPT), Plowshare projects probably will be requested by foreign countries, with coordination through the International Atomic Energy Authority (IAEA).

5.0022, INSTRUMENT DEVELOPMENT LABORATORY
W.W. VAUGHN, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

States to which project pertains: All states.

The purpose of the Instrument Development Laboratory is to originate and develop analytical techniques that are beneficial to geochemical and geologic investigations. A multi-disciplinary approach including electronics, physics, and chemistry is used to economically devise new methods or modify existing techniques to our specific needs. Of general interest are the adaptation and interpretation of the physical characteristics of the electromagnetic spectrum as determined by absorption, interference, reflectance, and fluorescence observations with special interest on the volatile or highly mobile elements.

Current objectives of the project include a two-way development program of simple reliable instrumental techniques using atomic absorpton and nuclear radiadion techniques for volatile or transitory elements occurring naturally. The two techniques will provide analytical data that is unique to each procedure and at the same time serve as correlative measurements to further validify values in the ppb (parts per billion) range of interest in geochemistry.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

5.0023, RADON PROGENY INHALATION EXPOSURES TO URANIUM MINERS
K.J. SCHIAGER, Colorado State University, School of Veterinary Medicine, *Fort Collins, Colorado* 80521

Objectives: This research was initiated as part of an integrated program to determine the effects of inhalation of radon and its daughters upon the induction of bronchogenic carcinoma in uranimum miners. Forty actively working uranium miners were selected from two mines on the Colorado plateau along with ten control subjects residing in the area who had no known occupational exposure to radon progeny or mine environments. The miners were equipped with personal dosimeters consisting of a battery-operated air sampling pump and a thermoluminescent dosimeter (TLD) worn on the miner's hat and designed to sample and measure the radioactivity in the air which the miner actually breathed. Blood and whisker samples were collected on a regular basis for measurement of polonium-210 and lead-210 to determine the correlation between the measured Working Level Month (WLM) exposures to radon progeny and the subsequent deposition of long-lived radioactive decay products in the whiskers. The objective was to develop a reliable bioassay procedure that would indicate cumulative exposures over definite time periods.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0024, A STUDY OF UNSUPPORTED 210 PO ION EXCHANGE IN SOILS, UPTAKE IN VEGETATION AND COMPARISON WITH DIRECT AERIAL DEPOSITION
R.L. WATTERS, Colorado State University, School of Veterinary Medicine, *Fort Collins, Colorado* 80521 (AT(11-1))

It is proposed to continue studies on the distribution coefficients of 210PoO2 in agricultural soils. Uptake in plants will be determined under various soil modification schemes. The chemical forms of the 210Po in soil and soil solution will continue to be investigated. Foliar deposition experiments are designed to determine migration in plant tissues, retention as a function of time and leaf alpha radiation dose effects.

Results: Distribution coefficients have indicated retention in the top soil layers. The distribution coefficients can be predicted from soil pH and silt content. Chemical species of 210Po in soil solution examined by electrophoresis and dialysis experiments indicated positive and negative species existed. Foliar absorption of 210PoO2 is appreciable.

5.0025, FIXATION OF CESIUM 137 BY SOIL CLAYS
B.L. SAWHNEY, Conn. Agric. Expt. Station, *New Haven, Connecticut* 06504 (AT(30-1))

The objectives of the proposed research are to determine the mechanism of Cs fixation by layer silicates and to investigate Cs sorption and fixation by whole soils

To determine the effect of the origin of charge on interlayer collapse and hence the Cs fixation, collapse in two trioctahedral montmorillonites was investigated during the past year. The lack of collapse and regular interstratification in these montmorillonites was similar to dioctahedral montmorillonites. Interlayer collapse will now be determined in dioctahedral vermiculites. Precise estimates of the collapsed layers in interstratified mixtures formed on sorption of Cs and K ions will be made using Fourier synthesis of the x-ray diffraction maxima.

Studies with an electron microprobe of the distribution of sorbed Cs in whole soils during the past year revealed that sand-sized weathered biotite particles in a soil core sorbed almost 8 times as much Cs as the clay. Sorption and distribution of some non-fixing type cation, as Ca, will be determined by the microprobe and compared to Cs distribution. Then, sorption and fixation of Cs by different soils of the region will be studied and related to structural and mineralogical characteristics of the soils.

5.0029, REACTOR SITE INVESTIGATIONS
E.H. BALTZ, U.S. Dept. of the Interior, Geological Survey, *Washington, District of Columbia* 20242

States to which project pertains: Various parts of the United States.

The project chief serves as consultant and advisor to the U.S. Atomic Energy Commission concerning the identification and evaluation of the regional and local geologic and seismologic factors and the foundation conditions that are pertinent to the suitability of designated sites and that may have a bearing on the design and construction of nuclear reactors, fuel reprocessing plants, and other nuclear facilities. Consultation includes reviews, as requested by the Commission, of data submitted by applicants as part of the Commission's licensing procedures for commercial nuclear facilities, and reviews of other independently determined geologic data relevant to the designated sites.

Advice and consultation is provided to the Commission for delineating investigations and research on the various geologic and seismologic factors to be considered in the evaluation and licensing of proposed nuclear facilities. Accumulating experience indicates that the knowledge of various regional and local geologic conditions, when applied to evaluations of specific sites, allows the engineering design criteria to be adapted closely to the environment with resulting increases in safety and decreases in cost of design and construction.

5.0030, RADIOACTIVE FOOD-CHAINS IN THE SUBARCTIC ENVIRONMENT
J.K. MIETTINEN, Helsingin Yli. Helsing. Univ., *Helsinki, Finland* (AT(30-1)-3446)

Whole body counting of Laplanders has revealed about 40 times higher body burdens of Cs-137 in them than in the average for other groups in the northern hemisphere. Environmental studies in Finnish Lapland have elucidated three food chains which cause these elevated body burdens. The most important of these leads from lichens through reindeer meat, another from flooded pastures through horsetails and sedges to cow's milk and the third one from the extremely nutrient- deficient fresh waters through plankton and fish to man.

The purpose of this project is to follow the future trends of the radioactivity in Lapps by the regular counting of the Cs-137 content by a mobile whole body counter and to analyze the radionuclide content in plants and animals to interpret the body burden. Average body burdens of reindeer breeders were maximum in April 1965, 1.5 microcurie with the highest individual values about 3 microcurie. Since then a decrease has taken place, the average value being in March 1970 0.5 microcurie. Sr- 90 and Fe-55 are other artificial fallout nuclides enriched by similar food chains, although not so efficiently as Cs-137. Pb-210 and Po-210 are 'natural fallout nuclides' enriched in Lapps similarly. Body burdens of all these nuclides are estimated from blood, placenta, teeth and urine analyses. They are about 3 to 15 times higher than the average. The food chains causing the elevated levels are being elucidated in detail.

Analyses of Pb-210 and Po-210 in surface waters and fish have revealed hydrospheric food chains efficiently enriching these natural nuclides. The beginning of the food chains at the lowest trophic level will be investigated.

5.0031, INVESTIGATION OF THE UNUSUAL BEHAVIOR OF CESIUM-137 AND OTHER RADIONUCLIDES IN THE FLORIDA ENVIRONMENT
J.F. GAMBLE, Univ. of Florida, School of Engineering, *Gainesville, Florida* 32601 (AT(40-1)4066)

For some time it has been recognized, but unexplained, that for equal fallout deposition, levels of cesium-137 in diet and man in Florida are higher than the U.S. national averages. The objective of this research is to determine the rates and mechanisms of environmental transport of cesium-137 in Florida relative to the human body burden of cesium-137 and to define the extent of unusual radioecological behavior in this location. Results of the program will have significance to power reactor siting, radioactive disposal, and the use of nuclear explosives for engineering applications in sub-tropical climates.

The persistence of cesium-137 in the diet (for example, in milk) during periods of low fallout rate indicates that in Florida the soil- root pathway plays an important part in transferring cesium-137 to the diet. The initial experimental design involves field, laboratory, and greenhouse investigations of cesium-137 behavior in Florida soils, including soil characteristics and soil-plant relationships.

Radioecological studies will be made in highly managed agricultural ecosystems, and to some extent in more natural ecosystems such as a hardwood forest. Concurrently, studies will be carried out to inventory the passage of cesium-137 through important food chains such as the beef and milk food chain to man.

5.0032, FIELD EXPERIMENTS ON THE FLUX OF RADIONUCLIDES THROUGH A SALT MARSH ECOSYSTEM
L.R. POMEROY, Univ. of Georgia, School of Arts, *Athens, Georgia* 30332 (AT(40-1))

The salt marshes of Eastern U.S. are well suited for ecological systems analysis, because they are simple, stable, and accessible. On the basis of 15 years of research we have constructed a compartmental model of the flux of phosphorus through the system. Simulation of the flux, using non-linear transfer coefficients, is being performed with an IBM 360-65 computer and a hybrid computer system consisting of a Philbrick analog computer and an RCA-55 digital computer. The model is responding in a stable, realistic way, and its complexity will now be increased.

A program of field research at the University of Georgia Marine Institute runs in parallel with the computer simulation, with as much interaction as possible between them. Emphasis is presently on flux of material through the grass, Spartina alterniflora, and the fiddler crabs, Uca spp.

Results: We have a 20-compartment flux diagram and a 5-compartment mathematical model. The latter is stable in computer simulation and is being used to explore the effects of variations in standing stocks and transfer rates in each compartment. The field program is being used to find and quantify pathways between compartments.

5.0033, RADIOMIMETIC EFFECT OF DRUGS AND FOOD ADDITIVES
K. SAX, Univ. of Georgia, Graduate School, *Athens, Georgia* 30601

The discovery by Levan and Kihlman in Sweden that caffeine is radiomimetic and breaks chromosomes, led us to study the effects of drugs, food additives, home insecticides and carcinogenic agents. We have found that caffeine, alcohol, sucaryl, various antioxidants used in foods, several home insecticides, cycasin which produces cancer in cattle, Veratrum which produces birth defects in sheep, and the carcinostatic drug Vinblastin all break the chromosomes of onion root tips grown in dilute solutions of these agents.

Recent work done in the winter of 1969 indicates that the type of absorbant paper used on which the seeds are grown may

modify the effect of the agent tested, although there is no difference in their effect on the water controls.

We want to continue research on the factors involved in the variation of the effects of radiomimetic agents caused by the various types of paper towelling used for seed germination. Metabolic changes are known to be a factor in the effect of radiomimetic agents ingested by animals.

We would also like to do more work on the synergistic effects of combined radiomimetic agents, such as caffeine and sodium cyclamate (sucaryl).

5.0035, CONTROLLED ENVIRONMENTAL RELEASE TEST (CERT) PROGRAM

P.G. VOILLEQUE, U.S. Atomic Energy Commission, Health Services Laboratory, *Idaho Falls, Idaho*

The CERT Program has the following broad objectives: (1) define variables which affect the transfer of radionuclides from the point of release to the atmosphere to a human receptor, (2) perform controlled experiments to measure the variables influencing the observed phenomena, and (3) develop and test predictive models of the processes involved. The transport of radioiodine through the milk-food chain has been studied since the inception of the CERT Program. Currently, the emphasis of the Program is shifting to analysis of (1) the air-to- vegetation transfer of radioactive particles and other radioactive gases and (2) mechanisms of removal of radioactivity from vegetation. Field tests involving the release of radioactive gases and aerosols are conducted over the 27-acre pasture of the Laboratory's Experimental Dairy Farm at the NRTS. The pasture is primarily mixed pasture grass but areas of other crops (e.g., alfalfa, sudangrass) are grown as required. Documented field releases will be used to obtain data to relate transfer rates and retention halftimes to variables which define meteorological and pasture conditions. Studies of the influence of specific variables on transfer and retention will be performed in controlled environment chambers in the Laboratory. Results of both types of experiments will be used in the development and testing of models.

Results: The transfer of radioiodine gas (I-2) from air to Manchur Bromegrass has been found to be dependent upon the percent of leaf area composed of open stomata. When the stomata are fully open, about sixty percent of the total transfer to the grass is via the stomata. It was also shown that Bromegrass sorbs only 2 - 5 percent of the I-2 which reaches the plant surfaces.

5.0036, BIO-ENVIRONMENTAL STUDIES

S.S. BRAR, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

The objective is to determine empirically the inventory, particularly of radioactivity, in various segments of the environment, and the flow through the environment from one compartment to another. Considerable emphasis is placed upon man as the ultimate receptor. Segments of the environment examined are air, precipitation, soil, water, and biota. The movement of material (initially nuclear weapon debris, more recently a host of industrial effluents, primarily airborne) through the atomosphere via precipitation to the surface is documented. Further movement in soil, water, and through foodchains is also examined. Gamma-ray emitters among the fallout radionuclides have been of prime interest, and neutron activation is employed in analyzing for stable elements. With the initiation of the Argonne Great Lakes Research Program, much of the effort in this category has been directed at radionuclide and trace element dynamics in Lake Michigan.

Results: A running inventory of gamma-ray emitting fission products has been maintained since the mid-1950's in air, soil, foodstuffs, and water. Levels of environmental radiation from fallout and natural sources has been measured for a number of years. The reconcentration of specific radionuclides in aquatic and terrestrial ecosytems has been identified. More recently, the degree of vertical mixing within Lake Michigan has been determined by using tritium and short-lived fission products as environmental tracers.

5.0038, A DETAILED STUDY OF THE ENERGY FLOW THROUGH THE BIOTA OF DOE RUN, MEADE COUNTY, KENTUCKY

L.A. KRUMHOLZ, Univ. of Louisville, Graduate School, *Louisville, Kentucky* 40208 (AT-(40-1)-3540)

The ecosystem of Doe Run, a torrent spring stream in north-central Kentucky, has been under intensive study since 1959 in an attempt to determine the pathways and fates of radioactive fission products within the system. Data gathered just before and after the series of Russian and American nuclear tests that began in September 1961 indicated that there was prompt uptake of fission product fallout from those tests. That accumulation reached a maximum in 1964 and by the summer of 1966 the amounts of radionuclides in the biota had returned essentially to the levels of the summer of 1961.

On the basis of those data it was proposed to inoculate the source of Doe Run with relatively short-lived radioisotopes of the two biologically important fission products, strontium 90 and cesium 137. Accordingly, the stream has been inoculated with cesium 134 on four occasions, in December 1966, in June and December 1967, and in June 1968. Also, it has been inoculated with strontium 85 in December 1968. The discharge at the source of the stream was different on the occasion of each inoculation, and the data on stream flow show that at low discharge (14-18 cfs) the concentration of radionuclide moved relatively slowly downstream, but became linearly dispersed over a relatively great distance, where as at high discharge (85 cfs) the concentration moved quite rapidly and remained compact.

Much of the cesium 134 was adsorbed to the bottom sediments and was rendered unavailable to the biota. Plants in the stream took up the cesium rather rapidly and in relatively high concentrations shortly after the inoculation, but most of that radioactivity had been lost with a month.

A study on the biology of the western blacknose dace, Rhinichthys atratulus meleagris Agassiz, was completed and is being prepared for publication in open literature.

A detailed study of the contribution of riparian leaf fall to the energy budget of Doe Run is underway as is a study of the biology of the white sucker Catostomus commersoni (Lacepede).

5.0039, ACCUMULATION AND MOVEMENT OF FISSION PRODUCTS IN SOILS AND PLANTS - II. MOVEMENT OF RADIONUCLIDE IONS IN SOILS

M.H. FRERE, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Beltsville, Maryland* 20705 (AT)

A large gap exists between knowledge of details of the chemical behavior of individual ion species in soils and the ways in which these interact in controlling their movement to and uptake by plant roots. The use of mathematical simulation of the overall process with the aid of high-speed computers permits the analysis of the systems to identify the dominant factors and to test the validity of various assumptions that can be made to simplify its description.

5. RADIATION

The development of the necessary computer programs describing the movement of calcium, potassium, nitrate, and bicarbonate ions has reached the operational stage. These are the dominant ions in fertile agricultural soils. The effects of water movement and the influence of salt content on the diffusion coefficients and the uptake of these and other ions will be examined for roots of different uptake requirements. The resulting data will provide insight into the treatments necessary to reduce the uptake of exchangeable radionuclide ions from contaminated soils.

Results: Simulations have been made to determine the influence of varying mass flow rates, and exchange capacity using a mathematical model, which takes into account the ion exchange capacity of the soil, mobility of the ions in the system, rate of water flow, and electrical potential. In several simulations it was concluded that the behavior of Sr and Cs can be deduced from the behavior of Ca and K as a first approximation. However, refinements are needed to interpret the effects of intermediate ranges of mass flow and other factors.

5.0040, DEVELOP METHOD OF REMOVING RADIO-ACTIVE CONTAMINANTS FROM AGRICULTURAL LAND

P.E. JAMES, U.S. Dept. of Agriculture, Agricultural Engin. Res. Div., *Beltsville, Maryland* 20705 (901-054-001(AEC))

OBJECTIVE: Develop and evaluate methods of safely producing crops on land contaminated by radioactive fallout.

APPROACH: Develop methods for reducing uptake of radioactive material by plant roots which are not as expensive or as difficult to perform as removal of top soil. Study practical application of punch planting which leaves radioactive material on the surface so tht roots feed primarily in uncontaminated soil. Also study cocooning method whereby top layer of soil is wrapped in a plastic envelope and plowed under. Plastic wrapper theoretically prevents entry of roots and subsequent uptake of radioactive elements.

PROGRESS: Manuscript was prepared for a Technical Bulletin entitled 'An Engineering Appraisal of Radioactive Fallout Decontamination Methods.' This manuscript describes preparation, distribution and measurement, and errors in measurements of radioactive tracers used as contaminants. It describes soil types, surface roughness and vegetation coverage of land decontaminated. Results of decontamination using farm machinery, earth-moving equipment and street sweepers are compared, and contaminant burial by a large plow is discussed. Effects on uptake of radioactive elements by plants grown through the surface of undisturbed land covered by radioactive fallout are compared with planting in soil having radioactive material plowed into it. Exploratory studies indicated corn leaves grown from mercurial treated, Ceresan M. seeds contained from 400 to 450 parts of mercury compared to 25 to 29 parts per billion in leaves from corn having no mercurial treatment.

SUPPORTED BY U.S. Dept. of Agriculture

5.0041, DEVELOP TECHNIQUES FOR DECONTAMINATING SOILS POLLUTED WITH RADIOACTIVE MATERIALS OR HEAVY METALS

W.D. KEMPER, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Beltsville, Maryland* 20705 (SWC-025-AB-4)

OBJECTIVE: Minimize the potential hazard of the accumulation of radioactive fission products or heavy metal elements in soils and plants from either chronic low levels or catastrophic high levels of contamination.

APPROACH: Basic studies are conducted on the soil chemistry of fission products, naturally occurring radioactive materials or heavy metals acting as soil poilutants and their accumulation by plants used as sources of human or animal food. Techniques for the prevention of this accumulation are developed. The uptake of the radioactive or polluting metals is studied in relation to soil management practices, the rooting habits of plants, and radiation damage to plant tissue.

PROGRESS: Studies were conducted with corn to evaluate soil and air as primary sources of Pb in plants. When air was the source, the lead content was higher in the nodes of the upper stalk than in those of the lower ones. When soil was the source, the reverse situation occurred. Corn tassels served as indicators of the particle size distribution of aerial lead. When most of it was in the smaller size fraction, the lead content of the tassels was higher than when most of the lead was in the larger size fraction of the aerosol. Zinc-cadmium interactions were studied. The addition of zinc in concentrations sufficient to suppress the accumulation of cadmium by radishes grown in a nutrient solution caused a considerable decrease in radish yield. The exchange behavior of lead and cadmium in soils with vermiculite- montmorillonite, illite, and kaolinite type clays followed the valency and concentration concepts normal under conditions where specific adsorption effects are absent.

5.0042, ACCUMULATION AND MOVEMENT OF FISSION PRODUCTS IN SOILS AND PLANTS - III. TREATMENT OF SOILS CONTAMINATED WITH RADIOACTIVE STRONTIUM

H M. KUNISHI, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Beltsville, Maryland* 20705 (AT)

Previous work has demonstrated that the addition of large amounts of soluble phosphates to surface soils can reduce the mobility of Sr-90 fallout that has accumulated in surface layers. Considerable phosphate reacts directly with the soil minerals and is not available for precipitation of strontium ions as inactive phosphates. Further examination of the precipitation processes will be undertaken to improve the effectiveness of the immobilization reaction by suppressing the reaction with soil minerals. The net effect of what happens to P will be followed by equilibrating samples in solutions containing different initial levels of P, to characterize the adsorption reactions at different rates of phosphate and lime addition.

The possibility of displacing strontium from soils using calcium in leaching waters will also be investigated since Sr ions and Ca ions adsorbed with approximately equal energy on soil materials.

Results: Alkaline orthophosphate salts can immobilize up to 98% of the divalent ions including radiostrontium in the upper layers of soil. Savings in the total amount of material that must be used for similar immobilization can be obtained by using a mixture of phosphate and fluoride instead of phosphate alone. In soils with exchange capacities no greater than 3meq/100g, the top 60 cm can be cleared of Sr ions by addition of 12 tons or less of gypsum and slow leaching. Enough sandy soils exist to provide adequate vegetable production after leaching following generalized contamination by radioactive strontium.

SUPPORTED BY U.S. Atomic Energy Commission

5.0043, CHEMISTRY, ACCUMULATION, AND MOVEMENT OF RADIOCATIVE MATERIALS

R.G. MENZEL, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Beltsville, Maryland* 20705 (SWCW8-AB-8)

OBJECTIVE: Minimize the potential hazard of fission product accumulation in soils and plants in case of either chronic, low-level contamination or catastrophic, high-level contamination.

APPROACH: Basic principles are studied affecting the accumulation of fission products and naturally occurring radioactive materials in plants that are used as sources of human food. Techniques for the removal of contaminated surface soil are worked out. The uptake of radioactive materials by plants is studied in relation to soil management practices, the rooting habits of plants, and radiation damage to plant tissues.

PROGRESS: Work is continuing on the nature of radiation damage to plants, and factors affecting the movement of radioactive materials in soils and their uptake by plants. Low doses of X-irradiation interfere with the bioelectric potential required for the normal photoreversible response of barley and ming bean roots. Ion movement and availability in soil and soil solution is characterized by equilibrium constants. Calculations for systems involving Na, K, Ca and Mg showed that a variation of any equilibrium constant affects the distribution of all the ions. Further work on methods to immobilize Sr in contaminated soil demonstrated that this can be achieved through the use of calcium hydroxide or

diammonium phosphate but it is impractical to use on a large scale.

SUPPORTED BY U.S. Dept. of Agriculture

5.0044, HEALTH HAZARDS OF URANIUM MINERS OF THE COLORADO PLATEAU
F.E. LUNDIN, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Natl. Insts. of Health, *Bethesda, Maryland* 20014

This project is to study the cause-specific mortality experience of underground uranium miners in relation to standard medical examination findings, cigarette smoking, and airborne radiation exposure data. To determine the quantitative relationship between airborne radiation and the incidence of respiratory cancer. To delineate the role of a number of factors which might influence carcinogenic response to airborne radiation. To develop realistic models for relating environmental exposure to cancer and other chronic diseases.

Study is made of miners and millers of the Colorado Plateau area who volunteered for at least one medical examination performed between 1950 and 1960. These workers are followed annually to ascertain their health status. Deaths are ascertained by review of local newspapers and the Social Security Administration. Death certificates are obtained and classified as to cause of death. Medical information is obtained from hospital and physicians' records.

Approximately 12,000 radon or radon-daughter measurements have been made from 1950 through 1963 and continue to be made with increasing frequency. These are used for quantitating the carcinogenic response to radiation.

5.0045, EXPERIMENTAL RADIONUCLIDE STUDIES
D.F. CAHILL, U.S. Environ. Protection Agcy., Twinbrook Research Laboratory, *Rockville, Maryland* 20852

The objectives of this program element are to determine some of the environmental characteristics and biologic effects of a wide spectrum of important radionuclides such as tritium, krypton, plutonium, strontium, and transuranic elements which are actual or potential environmental contaminants.

Attempts to attain these objectives will be pursued primarily through the definition of the dose-effect relationships of low-levels of environmental radionuclides in a variety of animal species with long- term observation of exposed animals for radiation-induced teratogenesis, carcinogenesis, and mutagenesis.

The Environmental Protection Agency is responsible for the definition of ambient radionuclide levels which strike a proper balance between the benefits and risks entailed. In the past, the NCRP and FRC have made recommendations on this subject but often their decisions on specific radionuclides were, of necessity, based on extrapolations from general dose-effect principles or on 'effects' data from similar radionuclides. This program element would fill some of the data gaps which exist for specific environmental radionuclides.

The results of this program element will be a series of reports on the biological and physico-chemical effects of specific environmental radionuclides on various stages of the ecosystem. Internally, these reports will be relayed to the Division of Criteria and Standards to assist in the formulation or revision of Radiation standards. Externally, reports will be made to the scientific community at large through publication of the experimental results in the open literature.

5.0046, HIGH TEMPERATURE STUDIES OF RADIOACTIVE FALLOUT PARTICLE FORMATION
C.E. ADAMS, U.S. Navy, Ordnance Laboratory, *Silver Spring, Maryland* 20910 (AT(49-7)3051)

The objective is to determine the rate-determining mechanisms which govern the uptake of radioactive vapors by molten or solid particles formed in the fireball of a nuclear explosion. Data on the actual uptake rates of selected radioactive vapors by various substrate materials will be obtained. This information will be used as input data for a computer-based model designed to predict the areal distribution and intensities of radioactive fallout fields resulting from nuclear explosions.

The laboratory work has utilized a two-temperature, vertical tube furnace in which radioactive vapors are generated in the low-temperature zone and are carried up into the high-temperature zone where they interact with the substrate samples. The vapor uptake rates have been measured as a function of vapor partial pressure, temperature and substrate particle size.

Results: Measurements of the uptake rates of the vapors of MoO3, TeO2, Rb and RbCl on substrates of a clay loam soil and a calcium ferrite have been completed. It was found that the rates of uptake could be described by an expression involving the condensation coefficient of the vapor on the substrate Henry's law constant for the vapor-substrate system and the diffusion constant of the condensed vapor material in the substrate. In cases where the condensation coefficient was less than approximately 10 the minus 3rd power the rate of uptake of the vapor was limited by the rate of diffusion of the vapor molecules through the air.

SUPPORTED BY U.S. Atomic Energy Commission

5.0047, RADIOACTIVE FALLOUT FORMATION
C.E. ADAMS, U.S. Navy, Ordnance Laboratory, *Silver Spring, Maryland* 20910

Technical Objective: Measure the kinetics and discover the rate- determining mechanisms which govern the condensation reactions between certain vaporized radioactive oxides and various molten or solid oxide substrates. This information is put into a physical-chemical model that can predict radiological fallout exposure-rate patterns.

SUPPORTED BY U.S. Dept. of Defense - Navy

5.0048, FUNDAMENTAL STUDIES IN FALLOUT FORMATION PROCESSES
I.J. RUSSELL, Boston College, School of Arts, *Chestnut Hill, Massachusetts* 02167 (AT(30-1))

A 9000 joule exploding wire facility is being used to study the incorporation of trace radioelements (fission products) in the condensed products of iron, aluminum and other metals in air and inert atmosphere explosions. Fractionation as a function of particle size can be large and qualitatively is in accord with the condensation behavior of the elements or their oxides in their pure states. Explicit investigation of the importance of the nature of the matrix and the concentration at the tracer level in determining the fractionation behavior of the elements will be studied in argon and air, over a range of specific energies.

Vapor phase uptake of trace fission products by molten oxides of various compositions is also being investigated. Systematizations are shown between uptake factors, the composition of the molten oxide, and the acid or basic character of the trace fission product oxide. For example the relative uptake of molybdenum and cesium vapors by a series of binary and ternary oxide substrates of differing ratios of Na2O, CuO, Al2O3, Fe2O3, and SiO2, exhibits an inverse relationship.

Electrochemical measurements of the oxide ion activity of oxide melts as a function of composition will be correlated with vapor phase uptake factors in forthcoming work.

5.0049, THE METABOLISM OF THE RARE EARTHS FOLLOWING INHALATION - PATHOLOGIC AND BIOCHEMICAL RESPONSE IN THE LUNG AND OTHER ORGANS
H.L. BERKE, Wayne State University, School of Medicine, *Detroit, Michigan* 48207 (AT(11-1))

The increased availability and widespread use of the rare earth poses the problem of their toxicity to the animal, particularly when inhaled. This study is concerned with the individual and comparative distribution and excretion in the Sprague-Dawley rat of scandium, yttrium, europium and ytterbium (and/or thulium) following exposure to aerosols of these isotopes. Modifications in the rate of lung clearance under normal and

varied conditions of intake, short term pathology and diagnostic tests of injury are particularly of interest. Specifically, a study designed to indicate the effects of pulmonary clearance following repetitive exposures using europium 152 and europium 154 is planned.

Results: Most of the distribution data for the various rare earths are now available and will be evaluated. A micro-separation technique for the blood lymphocyte has been developed. Using this technique, morphological changes in the peripheral lymphocyte have been observed following parenteral injections of uranyl nitrate in the rat similar to that after radiation insult. The peritoneal macrophage as transport agent for injected europium chloride as evidenced by blood leucocyte activity has been observed and the data is in preparation. Further investigations on the effects of added carrier, food, etc. on gastrointestinal absorption of europium is in progress.

5.0050, AEC OFF-SITE RADIOLOGICAL SAFETY PROGRAM

M.W. CARTER, U.S. Environ. Protection Agcy., Western Environ. Research Lab., *Las Vegas, Nevada* 89114

This program element will document external exposures to people living in the vicinity of nuclear testing activities and radioactivity levels in all pertinent environment media that occurs from those testing activities.

Nuclear testing activities of the Atomic Energy Commission provide the potential for releases of radioactivity to the environment. A program of continuous off-site radiological surveillance is necessary to document exposures and assure public safety.

A comprehensive off-site radiological safety program for nuclear testing activities including testing of weapons devices, underground engineering applications of nuclear explosives, and testing of experimental nuclear engines for propulsion of spacecraft, will be provided. Major program elements include ground and aerial monitoring, continuous environmental sampling and analysis, cloud and effluent tracking and sampling, public education and community relations, and provisions of medical and veterinary services to individuals claiming radiation injury.

The Western Environmental Research Laboratory maintains 105 air sampling stations in 22 western states for collecting daily air samples. Approximately 250 standby milk stations are activated annually, and about 36 routine milk stations and 95 routine water sources are sampled monthly. Thermoluminescent dosimeters are placed on 60 off-site residents and at 95 stations in the off-site area. Gamma exposure rate recorders are operated continuously at 32 of the air sampling stations. Complete radiological laboratory facilities handle all routine and special sample analyses. Medical direction and support is provided by the WERL Radiation Medicine Office and veterinary services are available from the Radiological Research Program.

5.0051, PHYSICAL AND CHEMICAL CHARACTERISTICS OF AEROSOLS PRODUCED FROM SOLUTIONS OF POLYVALENT NUCLIDES

G.M. KANAPILLY, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

The physical and chemical nature of aerosols produced from solutions of polyvalent metallic nuclides are being determined under various conditions. The physical and chemical nature of radioactive aerosols produced from solutions of nuclides by spills, explosions and fire are poorly understood at present. The specific and general information obtained in this study should provide valuable information in predicting the probable physical and chemical nature of the aerosols produced from solutions of radionuclides and thus enable one to estimate the relative health hazard of an inhalation exposure. The relative effects of various factors on the physical-chemical nature of aerosols is being investigated with solutions of metallic ions (Co, La, Ce, Sb, Ru, Zr, Nb and Mo) in one or more anionic (chloride, lactate, citrate, acetate, EDTA, hydroxide, oxalate, acetyl acetonate and tartrate) forms. Production of aerosols consists of nebulization of the desired solution, drying, degradation at temperatures up to 1100 degrees C and cooling at different rates. Electron microscopic studies, density measurements and determination of aerodynamic properties are being used for physical characterization. The chemical nature of aerosols is studied by tracer techniques, infrared absorption spectrometry, thermal analysis and other methods as applicable for specific cases.

RESULTS: The physical nature of the aerosols is affected by rate of drying, droplet sizes and rate of high temperature heating. Pure solutions of metal organic chelates tend to give hollow particles while micelle containing solutions yield relatively solid particles. The degradation temperature is important in determining the chemical nature of the aerosol particles. However, even at a degradation temperature of 1150 degrees C about 5% oxycarbonate or oxychlorides were found to be present in the aerosol particle produced from organic chelates or chlorides, respectively.

5.0052, BIOLOGICAL RESPONSE TO SMALL, DISCRETE, HIGHLY RADIOACTIVE PARTICLES

W.H. LANGHAM, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

Attempts are continuing to create mathematical models and biological data for a probabilistic approach to assessment of population risk from discrete, high specific-activity particles of exotic fuel forms such as those in various SNAP and SNP systems. Based largely on assumptions of biological parameters, computer models are being devised to estimate dose to cells in tissue as a function of residence time of the discrete source and distance from it. The model is extended further to relate probability of biological effect to number of cells at risk from the continuum of doses. Animal experiments are being conducted to observe tissue and cellular response around discrete sources as a function of time and calculated dose in an attempt to provide more experimental data to correlate with and extend the theoretical modeling.

The model developed in the previous year is undergoing continued updating as more data become available. Three of the skin lesions produced on monkey skin by particles of fissioned 235UC2 have been excised for histopathological examination. The examination has revealed no indication of neoplastic transformation, although changes in the germinal layer at the 472,000-rad site are atypical and should be thoroughly investigated. The monkey is being held for continued observation for possible long-term effects at those sites not excised. The period of observation of lesions produced in lungs of rats by particles of 238PuO2 and 239PuO2 has been extended to over 600 days.

5.0053, PHASE II PLANNING STUDY FOR EVALUATION OF RADIOACTIVE CONTAMINATION OF THE FOOD CHAIN

C.L. COMAR, State University of New York, School of Veterinary Medicine, *Ithaca, New York* 14850 (AT(30-1))

Preparation of a comprehensive and interpretive report on Fallout in the Food Chain utilizing data and concepts that have been developed and/or derived from program evaluations, experimental studies and worldwide fallout monitoring networks: Coverage will include: (1) The scope and significance of fallout levels observed throughout the world since regular reporting began following the 1957-58 nuclear test cycle (2) Review of remedial measures available for accidental and intentional releases considering alternatives, feasibility and relative effectiveness and (3) Review of nature and extent that typical dietary adjustments can be utilized or developed to minimize the internal hazard from radiocontaminants.

Appraisal of the needs for continuing an interpretive program dealing with fallout and similar environmental contaminants: Concepts developed under fallout programs should have greater application to peaceful program uses and can greatly assist in developing techniques for a better understanding of long-term behavior studies in other environmental problem areas (pesticides, pollutants, radionuclides in aquatic environments,

etc.) Environmental studies of a proposed nuclear power reactor site have been developed for the local area despite its remoteness from routine reporting networks. Information from previous studies, experimental programs and a ready source of worldwide data and literature have made such an appraisal possible.

5.0054, BIOLOGICAL EFFECTS OF IMPLANTED NUCLEAR ENERGY SOURCES FOR ARTIFICIAL HEART DEVICES (ABBREV)

F.A. KALLFELZ, State University of New York, School of Veterinary Medicine, *Ithaca, New York* 14850 (AT(30-1))

This study is designed to determine the biological effects from nuclear power sources which might be used to power artificial hearts in human beings. Continuation is planned of work along the following lines: implantation in Labrador retrievers of simulated sources containing appropriate amounts of californium 252 and strontium 90; clinical observations of implanted animals; further dosimetric studies. It is also planned to initiate preliminary studies using a plutonium 238 source.

Results: Dosimetric procedures have been worked out for the californium 252-strontium 90 sources; surgical procedures have been perfected for the implantation of the radioactive sources in the dog; clinical observations have been made on dogs that have carried these sources for several months. Part 3 of 7.

5.0055, PREDICTION OF TOTAL CONSUMPTION OF FALLOUT RADIONUCLIDES BY HUMANS FROM MILK (ABBREV)

F.W. LENGEMANN, State University of New York, School of Veterinary Medicine, *Ithaca, New York* 14850 (AT(30-1))

This phase has as its purpose the development of a model that will allow prediction of the total human intake of radioiodine, -cesium and -strontium from milk following contamination of pastures. The model is intended to apply to various conditions of biospheric contamination and to use a minimum number of samples to assess a nuclear incident. In the coming year we will utilize data developed in this laboratory to develop equations for predicting 90 Sr and 89 Sr intakes and to make error estimates for the predicted total intakes of radiocesium from milk.

Results to date: In the past year the model for prediction of radionuclide intake from milk has been broadened to apply to the situation where deposition of radioactivity takes place over a period of time. Of necessity, the sample requirements are greater; in addition to milk samples there is now a need to measure the rate of deposition of radioactive material in order to apply the models to any particular situation. Part 7 of 11.

5.0056, TISSUE CULTURE RESEARCH AND PLANS FOR ITS EXTENSION

E.J. HALL, Columbia University, School of Medicine, *New York, New York* 10032 (AT-(30-1)-2740)

Projects include the following: a) A measurement of the oxygen enhancement ratio for the mixed gamma-neutron radiation from californium-252, together with a study of the relative biological effectiveness of this radiation compared with radium gamma rays. b) A study of cells arrested at the G1/S interphase as an example of a cell population exhibiting recovery without progression - and the use of this system to study the effect of hypoxia in the recovery of sub-lethal damage.

Other projects that have been started in the past year include the effect of ultra high dose rate on the survival of mammalian cells and ultrasonic radiation damage produced in plant seedlings.

SUPPORTED BY U.S. Atomic Energy Commission

5.0057, RADIOACTIVITY AND TRACE ELEMENTS IN HUMAN BONE AND DIET

E.P. HARDY, U.S. Atomic Energy Commission, Health & Safety Laboratory, *New York, New York* 10014

Since the major source of radiation dose from fallout is the ingestion of contaminated food, a systematic program for estimating the dietary intake of selected radionuclides was undertaken in 1960. Quarterly samplings of foods representing 19 categories are carried out in New York City and San Francisco. In addition to Sr-90 which is assayed routinely, measurements have been made of the average daily per capita intake of Cs-137 and Ra-226 and natural strontium, barium and calcium. Since 1961, specimens of human vertebrae from accident victims or from persons whose metabolism could reasonably be assumed to have been normal before death, have been obtained in New York City and in San Francisco, for Sr-90 analyses. The purpose of these measurements has been to see if mechanisms of contamination of the diet and of the human skeleton could be deduced that could then be used to infer diet and bone Sr-90 concentrations at times and places where continuous measurements have not been made.

Results: Average bone and diet concentrations of Sr-90 slightly lower in 1968 compared to 1967. The average per capita intake of Sr-90 by San Francisco residents is less than half of that measured for New York City residents. The Sr-90 to Ca ratios of vertebrae from San Francisco children were correspondingly about one-half as great as those from New York City. There is some evidence that the peak in Sr-90 concentration in bone is shifting to older children. This is to be expected as dietary Sr-90 levels decline.

SUPPORTED BY U.S. Atomic Energy Commission

5.0058, LEVELS OF NATURAL RADIOACTIVITY IN MAN AND HIS ENVIRONMENT

G.A. WELFORD, U.S. Atomic Energy Commission, Health & Safety Laboratory, *New York, New York* 10014

This program documents the levels of naturally-occurring radionuclides in man and his environment. Special emphasis is placed on diet and subsequent deposition in man.

Uranium is presently being measured in lung, liver, and vertebrae samples from approximately 80 adults from the New York City area who had no occupational exposure to uranium.

Results: The dietary intake of lead-210 in New York City has been documented and is estimated to be 1.2 pCi/day. The highest individual diet category is shellfish (7.6 pCi/kg) but low intake makes this category insignificant in total intake of lead-210.

Additional radium-226 data for the average bone and daily intake levels observed in New York City, Chicago, and San Francisco showed: (pCi/gCa) Bone-Diet: New York City 0.036-1.7, Chicago 0.035-1.1, San Francisco 0.031-0.8.

SUPPORTED BY U.S. Atomic Energy Commission

5.0059, MEASUREMENT OF RADIONUCLIDES IN ESTUARINE AND MARINE ENVIRONMENTS (A COOPERATIVE AGREEMENT WITH THE ATOMIC ENERGY COMMISSION)

D.A. WOLFE, U.S. Dept. of the Interior, Bureau of Commercial Fisheries, *Beaufort, North Carolina* 28516

Many scientists have been concerned with the potential effects on marine organisms of low-level radioactive wastes from nuclear reactors on land as well as those on ships and submarines. Additionally, fission products from nuclear weapons are now found in the biosphere. To evaluate the ecological effects of radionuclides on organisms of commercial importance, it is necessary to know the quality, quantity, and form of radionuclides in estuarine and marine environments. These data are needed now so they can be utilized to establish base lines for existing levels of radioactivity in various components of estuarine and marine ecosystems, and so the mechanisms of uptake in the passage of radionuclides through food chains can be investigated.

Large samples of biological materials (1 kg.) are collected for analyses. These samples are either dry ashed or wet ashed to reduce the volume and to provide homogeneous samples. The gamma activity of the samples is then measured with a low background detection system consisting of a multichannel analyzer and a 4 x 4-inch sodium iodide crystal-detector housed in a 7-ton shield. The data for each sample are stored on binary-coded punched tapes which can be used in a computer for comparisons with the radioactivity of future or past samples.

5.0060, INTERAGENCY REVIEW OF THE HEALTH HAZARDS OF URANIUM MINING - COMPARISON OF EXPERIMENTAL TO EMPIRICAL RESULTS
P.J. WALSH, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Natl. Insts. of Health, *Durham, North Carolina* 27709

This project is part of a Federal, Interagency Review of the health hazards of uranium mining. Scientists from all the federal agencies are participating in providing information for the review and in reviewing the total body of information available on radiogenic lung cancer. The sub-group dealing with radiogenic lung cancer has identified responsible agencies and due dates for the various parts of the review. The NIEHS is the responsible agency for a comparison of empirical and experimental information on radiogenic lung cancer.

5.0061, RADIATION PATHWAYS STUDIES
B. KAHN, U.S. Environ. Protection Agcy., Natl. Environ. Research Center, *Cincinnati, Ohio* 45213

The object of this study is to investigate through field and laboratory research, the behavior, movement, and fate of radionuclides in the aquatic, terrestrial, and air environments for the purpose of assessing the radiation dose to man resulting through these multiple pathways. Radioactive materials may be discharged into the environment as a result of their use in nuclear power generation, in medical, industrial, and research applications, and in peaceful uses of nuclear energy as exemplified by stimulation of gas from rock formation by nuclear explosion.

Laboratory research studies will investigate pathways by which radionuclides, such as Pu239, Fe55, I129, Zn65, and tritium move through the environment to man. These investigations will deal primarily with metabolic studies concerned with uptake of selected radionuclides by specific environmental media, particularly living organisms. Field studies will also be conducted at selected sites such as at environmental nuclear power stations operating at full power. Boiling water reactor and pressurized water reactor facilities will be of primary concern for investigating the types, amounts, and environmental movement of radioactive materials discharged from them.

Reports on laboratory investigations will document results of uptake studies on certain radionuclides by selected organisms for publication in the open literature. These results will also be offered for use in providing a basis for setting radiation protection guides and standards. Results from field studies, particularly around operating nuclear facilities, will be reported in the literature for identifying and quantifying the radionuclides discharged to the environment and for defining the environmental pathways to man. Recommendations on monitoring and surveillance around such facilities will be developed as indicated by such study.

5.0062, BIOENVIRONMENTAL AND ECOLOGICAL DATA AND INFORMATION CENTER IN SUPPORT OF BIOENVIRONMENTAL AND RADIOLOGICAL SAFETY FEASIBILITY STUDIES
R.S. DAVIDSON, Battelle Memorial Institute, *Columbus, Ohio* 43201 (W-7405-ENG-92)

The Bioenvironmental and Ecological Information and Data Center (BEDIC) was occasioned by the extensive background information requirements needed for planning and management of Bioenvironmental and Radiological-Safety Feasibility Field Data Collection and Evaluation Studies relating to the nuclear excavation considerations of the Interoceanic Sea Level Canal Study (SLC). The criteria for data collection and evaluation as well as the selection of competent personnel and institutions required the study of the ecological literature and data pertinent to the Central American humid tropics.

BEDIC consists of an information and data storage and retrieval system with computer programs capable of coping with ecological, radioecological, and bioenvironmental research requirements. The capabilities of BEDIC serve the SLC program including a study of the possible ecological impact of interoceanic mixing, a study of the Bioenvironmental and Radiological Safety requirements for the AEC- Supplementary Test Site nuclear testing program, the development of a comprehensive review of the biological implications of tritium and various field survey and feasibility studies of AEC-Plowshare Programs. The cycling and transport of radionuclides in complex ecosystems have received major emphasis. The Center currently consists of approximately 7000 documents and bibliographic citations. BEDIC screens over 150 ecological and bioenvironmental periodicals and approximately 50 secondary publications on a regular basis.

In addition to continuation of the effects listed, the future activities of BEDIC will provide an ecological information and data base for remote inquiry by AEC. Because of extremely limited funding on this program, service to outside research investigators without compensation has not been possible.

5.0063, FISSION PRODUCT-SOIL ORGANIC MATTER COMPLEXES
R.H. MILLER, Ohio State University, Agricultural Experiment Sta., *Columbus, Ohio* 43210 (OHOSS-133)

OBJECTIVE: Separate, identify, and characterize the constituents of soil organic matter which complex fission products and determine the availability of fission products in fission product-organic matter complexes to plants and soil microorganisms.

APPROACH: Fission products will be incubated with several soil types. Organic matter complexes will be extracted, purified, and fractionated into various components. The distribution of fission products in these components will be studied. Attempts will be made to identify the compounds and functional groups which are active in the formation of these complexes. Plant availability of fission product- organic matter complexes will be measured in long term and short term uptake studies. The complexes will be introduced to sand cultures of plants which are allowed to grow to maturity in order to determine the movement of these fission products into edible portions of the plants. In addition the direct effect of the organic colloids on plant uptake will be measured through use of membrane equilibrium systems.

PROGRESS: A study was made of the formation of radiocolloids by Ce and the adsorption of Ce by equilibrated suspensions of humic acid, bentonite clay, and a mixture of these two colloids saturated with either Ca or K and H. The availability of Ce in these suspensions was measured using excised roots. Ionic strength, Ce concentration, and pH were critical factors affecting the equilibrium between radiocolloidal and monomeric Ce. Humic acid adsorbed much greater amounts of Ce and restricted uptake by barley and soybean roots more than did bentonite in the Ca saturated system. However, humic acid and bentonite adsorbed similar amounts of Ce in K-H saturated systems. Mixing bentonite and humic acid produced a synergistic-type effect in regard to Ce adsorption. It was proposed that the strong bonding of Ce by Ca-humic acid and humic acid-bentonite mixtures resulted from a more favorable orientation of the humic acid molecule for chelation of Ce. A multiple regression equation was presented which showed the effects of pH, ionic strength and Ce concentration on the formation of radiocolloidal Ce in salt solutions. Estimates based on the equation suggest that radiocolloidal Ce may not form in soil, but is likely to be present in significant amounts in laboratory studies.

5.0064, CHARACTERIZATION OF SOILS & VEGETATION FOR FUTURE EVALUATION OF RADIOACTIVE CONTAMINATION
F. HAGHIRI, Ohio Agric. Res. & Dev. Center, *Wooster, Ohio* 44691 (OHOSS-064-1)

OBJECTIVE: Field, laboratory, and greenhouse investigation of soils and vegetation from selected sites in Ohio to aid in evaluating the role of soil fixation, leaching, run-off, erosion, and possible concentration by plants in the disposition of radioactive contamination.

APPROACH: Soil samples, plant material, and run-off from Sr90 and untreated plots will be analyzed for Sr90 as well as the determination of other soil properties and composition. The soil profiles of the various plots are being characterized and the inorganic and organic fractions of the soil are being studied to determine their influence on the retention or release of Sr90. Soils and vegetation of small watersheds are being analyzed for gamma emitting isotopes. The uptake of Sr90 by various plant species grown under different conditions is underway.

PROGRESS: The movement of Sr in the soil profile and the removal of Sr by runoff, leachate and plant uptake as influenced by soil and crop management practices have been studied. Over a 7 year period, the net rate of Sr loss from 0-4" depth by various processes was maximum under gravel mulch and minimum under grass. The distribution of Sr in the top 12" of soil profile was influenced by cropping system and liming. The concentration of Sr at 8-12" depth under gravel mulch was about 10 times higher than grass. High rates of lime reduced the downward movement of Sr. The % of the initial application of Sr removed by runoff decreased while its loss by leachate increased during the 7 year period. The total % Sr removed by runoff, leachate and plant uptake after a 7 year period was 16.407, 13.655, 12.481, 10.828 and 9.231 for gravel mulch, rotation 'low lime', continuous corn, rotation 'high lime' and grass, respectively. Among various herbicides (fenac, benzac, trifluralin, paraquat, diquat, CIPC and pyramin) studied paraquat and diquat were the most effective in reducing the Sr adsorption by soil. Paraquat and diquat were most effective in replacing Sr in soils with low clay, low organic matter and high pH.

5.0065, EFFECTS OF RADIATION ON RESISTANCE TO INFECTION

W. FRIEDBERG, U.S. Dept. of Transportation, Civil Aeromedical Institute, *Oklahoma City, Oklahoma* (000613)

Exposure to ionizing radiation is a recognized hazard in civil aviation. Examples of some of the problem areas are a) Unshielded X-ray machines and radioisotopes, employed to locate defects in aircraft components. b) Repair of radio-luminescent aircraft instruments can result in inhalation or ingestion of radioactive materials. c) Shipment of radioisotopes on civil aircraft and military aircraft carrying nuclear weapons at or near civil airports can be hazardous to crash investigators. d) Aircraft flown through fallout from nuclear-weapons testing become contaminated. e) An unshielded klystron tube in a radar installation can produce X-rays of lethal intensity. f) SST passengers and crew will be exposed to ionizing radiation, a large portion of which will be protons and neutrons. g) Neutrons may be encountered in other aviation applications. The immune system is very sensitive to ionizing radiation, a major consequence of radiation exposure is lowered resistance to infection.

1. The radiation dose-immune capacity relationship will be determined for fission neutrons and X-rays. A principal objective is to find the RBE of neutrons at the lowest rad dose at which radiation effects can be detected. 2. The effect on immune capacity of fractionated irradiation with neutrons and X-rays will also be investigated by use of the parasite H. nana. 3. Effects of neutrons and X-rays on acquired immunity will be compared.

Document provided to SIE by the Highway Research Information Service.

5.0066, UPTAKE OF RADIACTIVE MATERIALS THROUGH FOOD CHAINS

S.R. HUSAIN, Pakistan Atomic Energy Comm., *Dacca, East Pakistan, Pakistan*

In this project the determination of Sr90 and Cs137 in cow's milk and also in crops and vegetation collected from different stations located at various places in East Pakistan will be made. Chemical separation method developed by U.K.A.E.A. (Windscale) P.G. Reports 156(w.) 155(w) and 282 (w) will be used. In some cases method developed by HASL (USAEC) will be applied. The overall chemical yeild of the strontium analysis will be determined with a strontium tracer. Samples of Sr90 will be counted by an automatic sample changer Low beta-II planchet counting equipment (Beckman) having background of less than 1/2 cpm. Final counting will be made by counting the yttrium-90 precipitate from the purified strontium fraction.

For Cs137 gamma-ray spectrometry will be used having a well-type NaI (Tl) crystal integral line asembly, and a 512 pulse height analyser attached to an oscilloscope and computer readout typewriter.

SUPPORTED BY Intl. Atomic Energy Agency - Austria

5.0067, ULTRAVIOLET LIGHT EFFECTS ON NUCLEIC ACID FORMATION AND GENETIC EVENTS IN BACTERIA

C.O. DOUDNEY, Albert Einstein Medical Center, *Philadelphia, Pennsylvania* 19141 (AT)

The investigation is concerned with the effect of ultraviolet light in damaging the nucleic acid of the bacterial cell to prevent DNA replication and interfere with RNA formation. It is devoted to studies of the cellular recovery mechanisms which result in resumption of normal macromolecular synthesis and the mistakes made in the process of these repair mechanisms which lead to mutation. It includes studies of the induction of non-photoreversible damage blocking normal semi- conservative DNA replication and presumably leading to a requirement for postirradiation RNA and protein formation in restoration of a new origin for DNA replication. It studies the non-recoverable but photoreversible damage inactivating DNA replication and its relation to cell lethality. It attempts to explore the nature of the mutation induction process and determine its possible relation to the non-conservative DNA replication involved in excision-repair, to recombination processes and to repair mechanisms dependent on initiation of semi-conservative DNA replication.

Results: Results suggest that excision of a pyrimidine dimer followed by recombination-repair is involved in UV-induced mutation. Further, they suggest that inactivation of DNA replication accounts for considerable UV-lethality.

SUPPORTED BY U.S. Atomic Energy Commission

5.0068, DISTRIBUTION & CYCLE OF RADIONUCLIDES & RELATED TRACE ELEMENTS IN MARINE ENVIRONMENT (ABBREV)

V. VOLJIN, Univ. Bucuresti, *Bucharest, Rumania*

The Danube influences the development of benthic organisms, modifying the dynamics of radionuclides in the Romanian coastal region of the Black Sea.

A study is being made of the transfer of 36Cl, 90Sr(90Y)137Cs from the sea and Danube water to the rocks of the continental shelf and to the sediments of the Delta.

The presence of these radionuclides in the Black Sea water was established earlier.

The rock structure and the phase transformations occurring under the effect of hydrostatic pressure and of temperature variation are studied by X-ray and neutron diffraction.

The data on the magnetic properties of the rock containing haematite are used for determining the conditions of formation of the latter and for comparing these conditions with those obtained on land.

The trace elements contained in the rock are determined by spectroscopy.

Conductance is measured in the sea and Danube water and then in the rock and sediment moistened with these waters and having varying grain size.

The diffusion coefficients for the above-mentioned radionuclides are determined by the instantaneous-source method proposed by E.K. Duursma.

The data obtained will make it possible to determine some characteristics of the dynamics of radionuclides under the specific conditions obtained in the Romanian coastal area.

5. RADIATION

5.0069, RADIONUCLIDE CYCLING IN AQUATIC ECOSYSTEMS
S.I. AUERBACH, U.S. Atomic Energy Commission, Ecological Sciences Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

The purpose of research on radionuclide cycling in aquatic ecosystems is to provide quantitative data for the interpretation and prediction of radionuclide movement and behavior in aquatic environments. With an understanding of the behavior of radionuclides in aquatic systems, we can also develop new uses and applications for radionuclides in research on fundamental ecological processes. The growing use of nuclear energy and the consequent release of small quantities of radioactive wastes requires information related to the longterm consequences of radionuclides in food chains. These data are needed for radionuclide transport models using the source, pathway, target or sink concept. A synthesis of results obtained from these investigations will help provide the predictive capability required for engineering design of nuclear installations to meet environmental safety criteria. Most of the research is with 90Sr, 137Cs, 106Ru, and 60Co which occur in White Oak Lake. Studies with warm water species of fish and their associated food organisms are carried out in the field and under controlled laboratory conditions. Parameters studied most intensively are assimilation, turnover, and concentration factors.

Results to Date: Bluegills in White Oak have constant K concentrations but 137Cs and Cs cycle seasonally with a peak concentration in February and a minimum in August. The cycling was due to a more rapid excretion rate, a lower level of 137Cs and Cs in the food supply during the summer and a seasonal fluctuation in food consumption rates. The assimilation of 137Cs from food is inversely related to the clay content of food items. Thus, the food chain is important in determining the concentration of 137Cs in different species of fish.

SUPPORTED BY U.S. Atomic Energy Commission

5.0070, CIVIL DEFENSE IMPLICATIONS OF A NUCLEAR POWER REACTOR IN A THERMONUCLEAR TARGET AREA
C.V. CHESTER, U.S. Atomic Energy Commission, Oak Ridge National Lab., *Oak Ridge, Tennessee* 37831 (W-7405-ENG-26)

The object of this program is to determine under what conditions and to what extent the fission product inventory of nuclear power reactors can complicate the problems of Civil Defense during and after nuclear attack. The core of a 1000-megawatt (electrical) power reactor at shutdown before refuelling contains gross radioactivity comparable to that from a 100 kt fission weapon a day after detonation, and a quantity of long lived fission products equal to those produced by about a 30- megaton fission weapon.

The approach to the problem is to determine the increase, if any, in the number of fatalities produced by a weapon due to the presence of a reactor in the target area, and the circumstances under which an increase in fatalities can occur. Reactor structures representative of important reactor types are analyzed (using high explosives on scale models where necessary) to determine the circumstances under which significant quantities of the core fission product inventory can be deposited outside the area depopulated by the weapon.

The effects upon nearby shelters of an uncontained meltdown of a reactor damaged by lower overpressures is being analyzed.

Results to date indicate that prompt ejection of the core from the reactor structure is required, if the core fission product inventory is to be deposited in quantity (due to scavenging by weapon fallout) outside the area depopulated by the weapon. Analysis of a Pressurized Water Reactor and a Liquid Metal Fast Breeder indicates that for prompt core ejection the weapon must burst so close that the reactor will be on the edge of the crater. For megaton weapons, this is beyond current delivery accuracies.

SUPPORTED BY U.S. Atomic Energy Commission

5.0071, AN INVESTIGATION INTO THE RELOCATION OF A PORTION OF THE WHEAT SUPPLY FOR NATIONAL SECURITY CONSIDERATIONS
C.D. GARLAND, U.S. Atomic Energy Commission, Oak Ridge National Lab., *Oak Ridge, Tennessee* 37831 (W-7405-ENG-26)

Considering the maldistribution of the United States food supply in relation to the population and the inherent problems of post-attack transportation, it appears logical to investigate the possibilities of relocating emergency food supplies to provide an adequately distributed emergency food supply.

The redistribution of wheat to areas of greater population concentration would make these supplies available to augment other food supplies and, if necessary, provide adequate nutrition to sustain people until transportation facilities could be restored. This relocation activity would greatly facilitate recovery in the post-attack environment.

The specific objectives of this study are, as follows: first, to identify areas in the continental United States with deficit food supplies and to estimate the cost of transporting wheat from areas of wheat production to areas of deficit food supplies; second, to estimate the cost of storing these wheat supplies in the respective areas; and third, to consider and analyze alternative institutional and administrative arrangements to achieve the program goals. This objective addresses itself to such questions as wheat ownership, release provisions, wheat acquisition practices, storage facilities, and the type and composition of the decision-making group.

Results: The wheat supply areas and the region with a relative food deficit have been identified. Wide variations exist in regional storage cost estimates. The typical food-deficit regions are the areas with normally higher wheat storage charges.

5.0072, ENVIRONMENTAL QUALITY STUDY PROJECT - ENVIRONMENTAL INFORMATION PROCESSING, STORAGE, AND RETRIEVAL.
J.H. GIBBONS, U.S. Atomic Energy Commission, Oak Ridge National Lab., *Oak Ridge, Tennessee* 37831 (W-7405-ENG-26)

We are utilizing the procedures and software of an existing bibliographic information center (NSIC) to abstract, keyword index, and computer-store references useful in work associated with routine discharges from power plants (and their effects). This includes such areas as measurements and controls of releases (radiological, chemical, and thermal); release methods and abatement techniques; movement and effects of release on the biosphere. This information is used internally to assist in the preparation of various state-of-the-art reviews and summaries on areas of interest. It is selectively distributed to interested individuals and groups based on their specific interests and requests. A keyworded abstract file ('PPIF') is also kept of projects being funded by AEC in environmental areas. Contact with the public is encouraged through correspondence and speaking engagements. The Project also attempts to aid the Commission upon request in specific areas of information such as program plan development.

Results: Certain existing, and several new, categories were added in the Nuclear Safety Information Center: (1) radionuclide release and movement in the environment; (2) environmental surveys, monitoring, and radiation exposure in man; (3) meteorological considerations; (4) radiation dose to man from radioactivity released to the environment; (5) effects of thermal modifications of ecological systems; and (6) effects of radionuclides and ionizing radiation on ecological systems. Keywords were developed and over 800 documents were abstracted, key worded, and entered into the computer.

SUPPORTED BY U.S. Atomic Energy Commission

5.0073, ENVIRONMENTAL QUALITY STUDY PROJECT - ENVIRONMENTAL ASPECTS OF RADIOLOGICAL DISCHARGES
J.H. GIBBONS, U.S. Atomic Energy Commission, Oak Ridge National Lab., *Oak Ridge, Tennessee* 37831 (W-7405-ENG-26)

While we know a great deal about radioactivity, its effects are of such consequence in time to man that highly detailed information is required. The object of this work is to develop new data and maintain state-of-art information on production, release, movement, and ultimate fate of radionuclides in the environment. Particular nuclides are chosen for study on the basis of their potential importance in their interaction with living matter, especially man. Our program is closely coordinated with other similar studies at ORNL. Ultimately the characterization of radiological source terms such as power plants will be combined with other radiation sources, followed through release, environmental movement including food chain, and dose (and dose commitment) to man. This will be done for river basin regions including multi-source points. Nuclear and non-nuclear radiation sources will be included. Environmental monitoring techniques and recommended procedures will be one objective. Another is a quantitative understanding of material balance of radionuclides implied by a variety of assumed power plants, reprocessing plants, and the like.

Results: A revision of a state-of-the-art of tritium was largely completed. A state-of-the-art on 85Kr was largely completed as was a review of Pu hazards. Studies of properties of actinide isotopes and their anticipated production rates were performed and a state-of-the-art review was commenced. It was found that there is a serious shortage of information on plant and mammalian uptake of americium and curium (extrapolation from plutonium is subject to large uncertainty).

SUPPORTED BY U.S. Atomic Energy Commission

5.0074, SYSTEMS ECOLOGY

R.A. GOLDSTEIN, U.S. Atomic Energy Commission, Ecological Sciences Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

Systems ecology research is developing methods to further man's understanding of the dynamic interrelations of organisms and the environments in which they live. Most of the research involves simulating natural processes in either stochastic or deterministic ways, so that useful predictions may be derived about environmental interactions. Systems ecology is attempting to perform environmental assessments that will help evaluate anti-pollution practices and devices. Systems engineering and operations research continue to influence some of the basic approaches being tested by ecologists. An immediate objective is to amass the mathematical tools ecologists will need to attack environmental problems at a level of sophistication that reflects the state of the art in other disciplines. Current uses of systems techniques are mostly limited to studying small parts of ecosystems; however, as more work is completed, the subsystems will become the starting point for models of whole ecosystems.

Results: A computer program was written to simulate the dynamic behavior of radionuclides in the environment in order to predict the internal doses resulting from intakes of food and water contaminated by power reactor waste releases. A Monte Carlo simulation approach was used to demonstrate energy budgets for predator-prey relationships in food chain dynamics. Parameter identification techniques, based on random search methods, were used to quantify a process model based on transient behavior data.

SUPPORTED BY U.S. Atomic Energy Commission

5.0075, RADIONUCLIDE CYCLING IN TERRESTRIAL ECOSYSTEM

D.E. REICHLE, U.S. Atomic Energy Commission, Ecological Sciences Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

Knowledge of the cycling of essential and nonessential elements whose radionuclides are potential terrestrial contaminants is needed for the assessment of impact of nuclear technology on the landscape. These studies are providing data on pathways and fluxes of radionuclides which complements efforts whereby radionuclide tracer techniques are being used to determine fundamental ecological processes occurring in the environment. Research on processes and components of terrestrial ecosystems emphasizes basic ecosystem processes as well as comparative interpretation of the 'unique' and 'common' attributes of the various aspects of the terrestrial landscape. Studies are underway in forest mesic ('Liriodendron tulipifera') and pasture ('Festuca-Andropogon' grasslands) ecosystems. Emphasis has been on the behavior of Cs137 but other tracers utilized include N15, Na22, Ca 45, Ca47, K42, P32 and P33 as well as research on micronutrients such as Mn54, Co60, Fe59 I131 and Ce144. The tracers are used to identify and quantify ecosystem processes such as productivity, soil-plant relations, animal food chains, and microbial decomposition. Analysis at the subsystem and system level is permitting the development of ecosystem models that will have predictive capability for the long-term movement of nutrient elements and fission products in the environment.

Results: Litterfall, standing crop and decomposition data were subjected to analysis and a compartment model developed to describe the mass and mineral element dynamics of the 'Liriodendron' forest floor system. Subsystem models were developed for grass foliage productivity, insect grazing and Cs137 cycling in the forest cryptogams. Similar compartment models were applied to energy flow, Ca, K, and Na fluxes through vegetation and arthropod components of the grassland ecosystem. Hickory and black gum trees are accumulators of Ce144 and Co60, respectively, but turnover of these radionuclides is slow because of strong chemical bonds in the xylem.

SUPPORTED BY U.S. Atomic Energy Commission

5.0076, ENVIRONMENTAL RADIATION STUDIES - EVALUATION OF NUTRIENT AND FISSION PRODUCT DISTRIBUTION AND MOVEMENT IN TERRESTRIAL ENVIRONMENTS

T. TAMURA, U.S. Atomic Energy Commission, Oak Ridge National Lab., *Oak Ridge, Tennessee* 37831 (W-7405-ENG-26)

This research is directed toward (1) defining the movement and mode of retention of nutrients and selected fission products in soils and sediments, (2) characterizing the influence of environmental parameters on the availability and/or exchangeability of these elements, (3) characterizing the forms of these elements in soils and sediments, and (4) relating the observed properties to changes in ecological parameters.

In addition to controlled field plot studies of available nutrients and fission product distribution, samples are collected from the plots, streams, and ponds for laboratory studies. Recently developed density gradient centrifugation techniques are used to segregate mineral and organic fractions. Segregated fractions are analyzed for nutrient and fission product contents using radioisotopic and selective removal techniques. X-ray diffraction and related mineral identification techniques are used to characterize the samples.

Results: Forms and quantities of phosphates in soils, suspended sediment, and bottom sediments were characterized by selective extraction procedures following density separations of mineral components. Samples known to have high calcium phosphates in noncalcareous soils showed similar amounts after segregation in the density gradient solution. This confirms that the density gradient solution does not dissolve and possibly translocate calcium phosphate. The calcium phosphates occur in association with different minerals which further suggests different forms and possibly different availability to plants.

5.0077, FIXATION REACTIONS

W.D. KLOBE, Univ. of Tennessee, U.T. A.E.C. Agric. Res. Lab., *Oak Ridge, Tennessee* 37830 (AT(40-1)GEN-242)

Some soils and clay minerals have the property of retaining certain cations and fission products in a relatively non-exchangeable state, thus affecting their availability for plant uptake. This process is commonly referred to as 'fixation', and is generally believed to be a result of cation entrapment following mineral lattice collapse and/or incorporation of cations into selective sorption sites. The present study is designed to determine: 1) The mechanism responsible for fixation. 2) The effect of different chemical environments on the amount of fixation. 3) The significance of fixation reactions in soils, as they affect the availability of nutrient cations and fission products.

Fixation was measured by the availability of specific cations for rapid isotopic-, or self-exchange in a well-stirred system. Increasing amounts of Cs were added to a Na-saturated vermiculite (less than 1% residual K) and the presence or absence of Na entrapment, along with X- ray diffraction results, helped distinguish between lattice collapse due to the formation of interstratified Cs- and Na-rich layers vs. edge collapse around vermiculite particles.

RESULTS: Cation fixation studies with hydrobiotite and vermiculite have been terminated, and the results are presented in two separate publications: a) Reactions Affecting Cation Exchange Kinetics in Vermiculite. 1967. Soil Sci. Soc. Amer. Proc. 31:744-749. b) Conditions Affecting Ca Fixation and Na Entrapment in Hydrobiotite and Vermiculite. 1970. (Approved for Publication in Soil Sci. Soc. Amer. Proc.) Results cannot be presented in detail, but were pertinent to the aforementioned objective.

5.0078, THE MOVEMENT OF TRITIUM IN SOIL-WATER SYSTEMS

W.D. KLOBE, Univ. of Tennessee, U.T. A.E.C. Agric. Res. Lab., *Oak Ridge, Tennessee* 37830 (AT(40-1)GEN-242)

This program is just being initiated. The objective is to develop standard growth media systems which can be used in extended studies of the distribution and plant uptake of fission products. Specifically, tritium might be used to measure soil moisture movments and uptake by plants. If tracer behavior under particular conditions within the soil is accounted for, a better understanding of soil-water movement and its implications to soil science is achieved.

A study of the movement of radioisotopes within the soil is complicated by the heterogeneous nature of soils and the many environmental factors which affect such movement. However, basic information on the dissipation of radioactive materials as related to soil characteristics, climatic factors, and vegetation can be helpful in resolving many environmental problems. For example, it might povide a better understanding of the contamination problems and soil-water movement processes in the vicinity of various nuclear reactors.

A perfusion system will be used to study tritium availability and distribution in a well-characterized soil. The system will allow precise control of soil moisture content and soil atmospheric composition by regulating the pressure and composition of gases surrounding a perforated soil column within a pressurized chamber.

RESULTS: 1. Initial experiments pertaining to the study of tritium availability and distribution in soils have been outlined. 2. Soil samples have been procured and are being characterized. 3. Soil extraction and liquid scintillation counting techniques are being reviewed. 4. A perfusion system is being constructed for controlling temperature, pressure and moisture conditions in soil columns 12" high and 1" in diameter.

5.0079, RADIATION INJURY ASSOCIATED WITH HIGH ALTITUDE FLIGHTS AND SPACE OPERATIONS

J.H. KIRK, U.S. Air Force, School of Aerospace Med., *San Antonio, Texas* 78235

Technical Objective: Man's ability to perform essential mission tasks will be influenced by his surrounding environment, radiation exposure from nuclear sources and in high altitude or space shuttle operations, i.e. gamma rays, protons, electrons and high Z particles must be considered. Additionally, interactions of other flight stresses combined with radiations must be ascertained. The objectives include evaluation of acute and delayed effects, combined stresses, modes of action and estimations of repair ability in appropriate experimental animals following exposures to these various types of radiation. Comparative data relative to radiation hazards, predictions as to degree of functional impairment and exposure criteria will be developed.

5.0081, ENVIRONMENTAL EFFECTS ON THE CONTENT OF CS137 IN MILK

R.C. PENDLETON, Univ. of Utah, School of Letters, *Salt Lake City, Utah* 84112

We propose to determine the rate of movement and quantity of 90-Sr and 137-Cs transported from mountain watersheds to croplands. Investigations will center about dairy farms on which rapid accretions of fallout nuclides resulting from surface transport have been observed- 'hot-spot farms' which have consistently shown highest level of radionuclides in milk, solids and vegetation over a six year study period. Effects of overgrazing, poor drainage, irrigation methods, deposition of silt in reservoirs and lakes, on the movement of fallout nuclides to lowlands soils will be assessed.

5.0082, THE ANALYSIS OF NATURAL SYSTEMS

L.L. EBERHARDT, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

The study is to develop mathematical models for the description and interpretation of ecological data, and to provide the analytical framework for field and laboratory research activities. The problems include experimental design, design of sampling programs, formulation of methods of estimation, hypothesis testing, structuring of computer simulation models, and analysis of ecological data. A further objective is the development of mathematical and computer simulation models of radionuclie transfer from the atmosphere through food chains and to improve understanding of the ecological processes.

Results: Active support to projects has included population estimation, study of home range, plant abundance, and influence of environmental factors on productivity. Development of radionuclide uptake and retention models continued and was extended to pesticides (Cl-36 labelled-DDT). The first order kinetics models appropriate to radionuclide food-chain studies seem also appropriate for pesticides. The model of the Alaskan lichen-caribou-Eskimo food chain was refined and improved.

5.0084, IRON-55 AND LEAD IN THE HUMAN POPULATION OF THE WORLD

C.E. JENKINS, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)1830)

The transfer of Fe-55 from fallout into the various phases of the biosphere, with special emphasis on the levels in man and in the food chains leading to human consumption, is being studied. Investigations are being made to determine the overall behavior of Fe-55, including its concentration with depth, its distribution through the food chains, and how much has actually reached the ocean floor and is contained in the sediments. Iron-55 in salmon and the food chains leading to the salmon are extensively studied since salmon contain high levels of Fe-55. These measurements permit the distribution of Fe-55 to be studied as a function of latitude, salmon species, sex, age, and trophic feeding level. The scope of the work includes the use of existing Fe-55 burdens in the general population to study the uptake and retention of iron with different ages, sex, and diet.

Results: The worldwide Fe-55 and iron concentrations measured in men and women's blood samples correlate well with Fe-55 levels in the atmosphere and vary as the yearly rainfall at the collection site. Concentrations of Fe-55 in cattle blood correlate with the expected concentration in vegetation and follow a biological half-life of 1.72 years. Iron-55 in Alaskan fish-eating natives is tenfold higher than in Richland, Washington, residents and the level is declining at a more rapid rate, reflecting the much higher turnover rate for iron in the foods from the marine biosphere.

5.0085, CHARACTERISTICS OF HANFORD PROJECT SOILS

R.E. WILDUNG, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

The emphasis of soils research is on the Arid Land Ecology (ALE) Reserve and serves to characterize and delineate soil units and to correlate them with biotic components of natural ecosystems. Characterizations and delineations involve the definition of physical and chemical soil properties associated with individual organisms or communities and nutrient cycling through soil-plant systems. Detailed studies of fundamental soil processes and transformations are conducted. The fate of soil organic matter, the flow of carbon and energy through soil, and the availability of mineral nutrients from weathering processes have the ultimate goal of defining the role of essential soil properties in ecosystem dynamics.

Results: Measurement of CO2 evolution from soils amended with native grass tissue indicates that (1) rates are temperature and moisture dependent, (2) soil microorganisms are capable of easily degrading higher quantities of organic matter than occurs naturally, and (3) root tissue is more resistant to decay than shoot tissue. The chemical analyses of field collected samples indicate soil-plant community differences.

SUPPORTED BY U.S. Atomic Energy Commission

5.0086, MACRO-NEKTON INVESTIGATIONS OFF THE COLUMBIA RIVER MOUTH

A.T. PRUTER, U.S. Dept. of the Interior, Bureau of Commercial Fisheries, *Seattle, Washington* 98102 (AT(49-7)1971)

The purpose of this project is to assess the magnitude and distribution of the dominant pelagic and zooplankton fauna inhabiting the offshore environment adjacent to the Columbia River mouth, and to determine the role that these fish and invertebrate populations may play in the biological transplant of radionuclides originating from the Columbia River - Hanford reactor site. Major pelagic fish resources of the study include Pacific hake, northern anchovy, various smelts and rockfishes, and lantern fishes. Some of these species are now being intensively exploited and most of them feed on zooplankton species which have an affinity for certain radionuclides.

Acoustic surveys and sampling with midwater trawl gear is conducted over a 3,200 square mile contiguous to the Columbia River mouth. All catches are enumerated by species and samples of the selected species are collected for radio-analysis by the University of Washington Laboratory of Radiation Ecology and the Oregon State University Department of Oceanography.

To date, two cruises have been completed; one in February, 1969 and the other in May, 1969. The February cruise was severely restricted because of inclement weather. Two hundred miles of trackline were surveyed in the immediate vicinity of the Columbia River mouth. The most abundant fishes encountered were the yellowtail rockfish ('Sebastodes flavidus'), anchovy ('Engraulis mordax'), and the Columbia River smelt ('Thaleichythys pacificus'). The May cruise provided an opportunity to measure various parameters of the trawl sampling gear. During the cruise 850 miles of trackline were acoustically surveyed. The dominant species present in the study areas was Pacific hake ('Merluccius productus'). Results of the two cruises have been useful primarily in providing a background of information for use in designing future surveys on this project.

5.0087, STUDIES OF THE NATURAL ALPHA-EMITTING RADIOISOTOPES IN MARINE ORGANISMS

T.M. BEASLEY, Univ. of Washington, School of Fisheries, *Seattle, Washington* 98105 (AT(45-1)2225014)

The objective of this research is to characterize the levels of the naturally occurring alpha-emitting radionuclides in marine biota. The results will permit an evaluation of the role played by these isotopes in contributing to the natural radiation environment of marine organisms.

SUPPORTED BY U.S. Atomic Energy Commission

5.0088, THE PHOTOBIOLOGY AND PHOTOCHEMISTRY OF RIBONUCLEIC ACIDS

M.P. GORDON, Univ. of Washington, School of Medicine, *Seattle, Washington* 98105 (AT(45-1)2225,015)

These studies have as their goal the nature of the alterations produced in RNA by ultraviolet light and the nature of the photoreactivating systems which can reverse these deleterious alterations. Photoreactivable irradiated tobacco mosaic virus ribonucleic acid (TMV-RNA) contains pyrimidine dimers, while the non- photoreactivable RNA from irradiated whole virus does not. The coat protein of TMV will form hybrid virus particles with potato virus X RNA, and these hybrid particles cannot be photoreactivated. The polyhedral nucleoprotein particle consisting of a hollow shell of cowpea chlorotic mottle virus protein enclosing TMV-RNA does show photoreactivation. These results indicate a possible correlation between photoreactivation and the presence of pyrimidine dimers containing a cyclobutane ring. The ability of assay plants to photoreactivate TMV-RNA is slowly lost upon dark treatment and regained within 10 hours of illumination with white light. Irradiation of assay plants with 253.7 nm radiation blocks photoreactivation of TMV-RNA. This block is removed by illumination with white light for short periods of about 2 hours. An 'in vitro' system has been obtained which appears to carry out the photoreactivation of irradiated TMV-RNA. Methods for the large-scale preparation of chloroplasts and chloroplast tRNA's have been developed. An experimental system consisting of mammalian cells in culture containing tobacco leaf chloroplasts is being developed.

5.0089, EXCHANGE OF LYOTROPIC SERIES CATIONS BY MICACEOUS VERMICULITES IN RELATION TO SURFACE CONFIGURATIONS OBSERVED BY ELECTRON MICROSCOPY

M.L. JACKSON, Univ. of Wisconsin, School of Agriculture, *Madison, Wisconsin* (AT(11-1)-1515)

Objective: To obtain precise knowledge of lyotropic series cation exchange and fixation mechanisms in micaceous vermiculites, including fission product cations such as 137-Cs ion and 90-Sr ions, as influenced by layer configurations and hydroxy sesquioxide coatings examined by electron microscopy.

Scientific Background for Study: Micaceous vermiculites (a) are ubiquitous in soils and sediments through inheritance from metamorphic rocks, fluvial sediments and aerosolic dusts carrying nuclear fission products in rainfall; (b) undergo exchange with lyotropic series cations and retain (fix) certain fission products. Partial cleavage creates wedges which have steric effects in cation

exchange selectivity, particularly of 137-Cs ion, associated sesquioxide coatings are thought to fix cations such as 90-Sr ions.

Proposed Procedure: Cation exchange and fixation mechanisms involving layer configurations and colloidal sesquioxide coatings of micaceous vermiculites from the sources above will be investigated by radiochemical, high resolution electron microscopy (replica, stereo- scanning, and ultramicrotomy), and chemical extraction techniques. The findings will be correlated with nuclear fallout and waste problems.

Test Objects and Agents: Soils, tropospheric dusts, other sediments, and model exchangers, all containing micaceous vermiculite. Radiochemicals, including 137-Cs ion and 90-Sr ions. Electron microscopes and replicato.

Results: Research thus far has provided basic information on micaceous vermiculites: (1) on the relationship of lyotropic cation exchange and selectivity to the layer charge density and interlayer wedges, by radiochemical and electron microscopic techniques: (2) on the effect of sesquioxide coatings in causing cation exchange capacity (CEC) lowering, pH dependent CEC, and layer lifting; and (3) on identification of tropospheric dusts bearing micaceous vermiculite as additions to soils and sediments (through the oxygen isotopic composition of the 'marker' mineral quartz) and carrying 137-Cs ion and retaining it against replacement by Ca ions of CaCl2.

B. EFFECTS

Physical, Chemical, and Biological Injury. Medical Studies Utilizing Radiation Are Excluded.

5.0090, EFFECTS OF AGING ON SOME ENERGY-LINKED FUNCTIONS OF PLANT MITOCHONDRIA

B. TRUELOVE, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA-05-0862)

OBJECTIVE: Investigate the effects of aging and high energy gamma ray irradiation of seeds, seedlings and isolated mitochondria on several measurable parameters of isolated mitochondria.

APPROACH: Seeds and growing plants will be allowed to age naturally or aging will be simulated by varying the environment. Mitochondria will be isolated from the plant tissues and examined to see what effect the tissue pretreatment has had on a variety of mitochondrial energy-linked functions including conformational change, oxidative phosphorylation and ion accumulation abilities.

PROGRESS. The work so far has only been of a preliminary nature and has concentrated on the effects of radiation on germination and subsequent growth of bean seeds (Phaseolus vulgaris var. Black Valentine). Air-dried seed subjected to 10,000 rads of gamma irradiation showed a slight decrease in germination and a reduction in growth of epicotyl and leaves. Seed given 20,000 rads were largely killed prior to or immediately post germination and showed very little aerial growth. Seed soaked in water prior to irradiation were much more sensitive to radiation damage, the degree of sensitivity being related to hours of soaking prior to irradiation. Generally, the longer the soaking period the lower the seed viability and subsequent seedling growth. Some evidence has been obtained which suggests that seeds soaked for 24 hrs and given low levels of radiation (500-2,000 rads) showed a more rapid rate of germination and increased early growth of the seedlings. Radiation, at the levels used, affects the respiration of embryonic tissue but has no apparent effect on the respiration of the pre-existing cotyledon tissue.

5.0091, EFFECT OF RADIATION ON THYROID PROTEIN BIOSYNTHESIS

J.M. HERSHMAN, U.S. Veterans Administration, Hospital, *Birmingham, Alabama* 35233

X-irradiation of microsomal particles prepared from pig thyroid homogenates by conventional methods with 100,000 rads before incubation with radioactive leucine reduced protein synthesis as much as 60% of that of a non-irradiated control. The effect of the radiation was most pronounced at early incubation times (15-30) and at low concentrations of cytoplasmic elements. Beta-mercaptoethanol, which was necessary for protein synthesis, reduced the amount of X-ray damage to protein synthesis considerably when added before X-irradiation but had minimal effect when added after X-irradiation.

5.0093, BEHAVORIAL EFFECTS OF LOW INTENSITY UHF RADIATION

S.F. KORBEL, Univ. of Arkansas, Graduate School, *Fayetteville, Arkansas* 72701

The objectives of the proposed project include investigations of the following variables under low intensity, low frequency (500 MHz) UHF radiation: (a) Behavioral effects; UHF-induced behavioral changes such as activity, emotionality, learning, and stress are being studied; and (b) Parameters: The second objective is the exploration of behavioral changes as a function of the following parameters: (1) Power intensity levels: Evidence indicates that activity is differentially affected by different power levels (.43-.15 mw, 1.75 mw/sq cm, 3.50 mw/sq cm; (2) After effects: One major effect of low intensity UHF radiation, hyoactivity, continues to occur for a short period of time after UHF is terminated; (3) Age of organism: Possible UHF-induced behavioral changes as related to age of organism (78, 18, 138 day old rats at first exposure to UHF fields) will be investigated.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0094, THE ROLE OF ENERGY METABOLISM IN REPAIR AND MACROMOLECULE SYNTHESIS AFTER IRRADIATION

G.V. DALRYMPLE, U.S. Veterans Administration, Hospital, *Little Rock, Arkansas* 72206

DNA rejoining by L cells and by rat sarcoma cells was measured by three methods: 1) alkaline sucrose sedimentation, 2) polynucleotide kinase, and 3) DNA polymerase. These studies showed that DNA breaks are produced in a dose-dependent manner and they are rapidly rejoined after irradiation. The rejoining, however, is inhibited by uncoupling concentrations of dinitrophenol. The rejoining of DNA breaks by mouse liver, mouse spleen, and rat sarcoma (as a solid tumor) occurred during the postirradiation period. The results indicated the DNA breaks (as measured by alkaline sucrose sedimentation) were rejoined at the same rate the 5' termini (as measured by polynucleotide kinase) and 3'OH termini (as measured by DNA polymerase) disappeared. We interpret these data to mean that radiation produces a large number of DNA breaks characterized by 5'PO4 - 3'OH termini. Very likely DNA ligase is responsible for this rejoining. Since DNA ligase requires ATP as a co- factor, dinitrophenol treatment would be expected to inhibit the action of this enzyme.

We have found that treating L cells and rat sarcoma cells with a detergent-based lysing solution (2% TIPNS, 1% para-aminosalicylate, 6% butanol, pH 13) produces a most interesting result. Cells were prelabeled with 3HTdR for 2 generations, then suspended in Hank's balanced salts solution without glucose (HBSS). After irradiation (250 - 10,000 rads), the cells were lysed. Within a few minutes of lysis a mucoid precipitate formed

which contained most of the radioactivity. With increasing dose, a decreasing amount of radioactivity appeared in the precipitate. We, tentatively, have interpreted these findings as due to alterations in the DNA-protein interactions which allow greater solubility in the detergent system.

SUPPORTED BY U.S. Veterans Administration

5.0095, EFFECT OF IRRADIATION ON MEMBRANE AND TRANSPORT CHARACTERISTICS OF ISOLATED FROG SKIN

G.V. DALRYMPLE, U.S. Veterans Administration, Hospital, *Little Rock, Arkansas* 72206

Purpose: Ionizing radiation causes profound alterations in cellular energetics and metabolism which leads to changes in permeability characteristics and in active transport by the affected cells. The proposed investigation will define time-dose relationships in a well defined, accessible system. The technique introduced by Ussing and Zerahn to study active transport in the isolated frog skin will be used.

Approach: Half of whole, intact frogs (Rana pipiens) will be irradiated and paired experiments will be performed at varying intervals after irradiation. Doses of 0, 1000, and 10,000 rads will be used. The skin from the irradiated and non-irradiated sides will be mounted as flat sheets between lucite chambers containing frog Ringer's solution. Each half chamber will have a volume of 5.0 ml and the area of skin exposed to Ringer's soluton will be 3.14 cm squared.

Following a suitable equilibration period (generally an hour) the skins are short-circuited and the short-circuit current taken as a measure of net sodium flux. When the short-circuit reaches a steady value, radioactive sodium (Na-22) is added to the outside solution of both skins. Sampling of the inside solutions begins immediately after addition of the tracer. A total of 13-14 samples will be taken at intervals over 45 to 50 minutes. This time should be to allow a sufficient steady state tracer flux to occur. A single sample of the outside solution is taken near the end of the experment. At the conclusion of the experiment the skin is removed, blotted, and the area of the skin exposed to the Ringer's solution cut out and counted to assay the amount of radioactive sodium present.

Sodium concentration will be determined by atomic absorption spectrophotometry (at the University of Arkansas Medical Center).

The proposed experimental approach will permit comparison of 'non- irradiated' vs. 'irradiated' skin from the same frog and thereby possibly permit early detection of subtle alterations produced by irradiation. It also allows the calculation of undirectional sodium fluxes across the two faces of the transporting cells and will be used to identify the site(s) upon which irradiation acts to alter sodium transport.

SUPPORTED BY U.S. Veterans Administration

5.0096, STUDIES ON ENZYMIC REPAIR OF RADIATION INJURY IN MAMMALIAN CELLS

J.L. SANDERS, U.S. Veterans Administration, Hospital, *Little Rock, Arkansas* 72206

Cultured mammalian cells possess the ability to repair injury sustained from ionizing radiation. Recent investigations have shown that repair can be modified by inhibitors of energy metabolism. Specifically, agents which uncouple aerobic oxidative phosphorylation (dinitrophenol and arsenate) enhance repair. In contrast, chemical inhibitors of the electron transport sytem (azide and cyanide) show no effect. Fluoride, which inhibits anaerobic glycolysis, appears to prevent repair in some cultured mammalian cells. This diversity of effects, resulting from inhibitors with different modes of action, offers us an opportunity to study the role of energy metabolism in the repair of radiation injury.

The proposed research will center around the following points: (1) The radiation survival characteristics of cultured cells being treated with inhibitors of energy metabolism; (2) macromolecular synthesis in irradiated cells undergoing general metabolic inhibition; (3) the response of synchronized cells compared to that of randomly dividing cells; (4) the survival and biochemical responses of cells irradiated under varying degrees of oxygen tension; (5) the behavior of culture cells having different tissue origins. These investigations should give insight into the fundamental mechanism underlying repair of radiation injury in mammalian cells.

Also, these studies have significance in a number of areas concerned with radiation injury, including radiotherapy, mammalian genetics and exobiology.

SUPPORTED BY U.S. Veterans Administration

5.0097, RADIATION INDUCED CHANGES IN NEONATAL NERVOUS SYSTEM

S.A. GILMORE, Univ. of Arkansas, School of Medicine, *Little Rock, Arkansas* 72005

The purpose of this project is to study the changes induced by exposing a limited portion of the immature spinal cord to ionizing radiation. The animal used in this project is the rat which is irradiated on the third postnatal day. The responses to the irradiation procedure are evaluated by neurologic, light and electron microscopic, histochemical and autoradiographic methods. In contrast to the fetal period during which exposure to radiation drastically alters the neuronal population, exposure during this early postnatal period alters the neuroglial population and, consequently, myelin. Several studies are concerned with this radiation-induced delay in myelinogenesis. Furthermore, exposure to a certain amount of radiation is followed by the development of Schwann cells and peripheral myelin within the spinal cord. Long-term (two year) studies of changes induced by exposure to small amounts of Xrays are under investigation. Although most studies in the initial phase of the project were designed to determine the damage incurred by the spinal cord, some of the current studies are for the purpose of determining the abilities of the immature spinal cord to recover from radiation-induced damage.

5.0098, CHROMOSOME ABERRATIONS IN PERIPHERAL BLOOD LYMPHOCYTES IN AREAS OF HIGHER ATMOSPHERIC CONCENTRATIONS OF NATURAL RADON-222

J. POHLRULING, Austrian Academy of Sciences, *Innsbruck, Austria*

The question whether continous low-level irradiation or small intermittent exposures cause biological consequences is approached by using chromosome aberrations of the peripheral blood lymphocytes as indication. Blood samples are taken repeatedly from people living or working in the area of the Austrian Spa Badgastein. They are grouped according to their radiation load: A) Thermal Gallery at Bockstein 1) Miners, trainleaders and medical doctors working in the 'Thermal Gallery' a treatment place within a disused gold-mine whose atmosphere contains Rn222 and daughters at high air temperature and humidity (29-95 WLM/a). 2) Attending personnel for the patients in the connected spa house (2-9 WLM/a). B) At Badgastein and Hofgastein 3) watering attendants in spa and treatment houses. 4) Inhabitants of Badgastein- Center where the hot springs containing Rn222 originate. 5) All the other inhabitants living in this region. The blood doses owing to Rn222 and daughters inhalation is about 15; 6 and 3 mrad/a resp. for group 3, 4 and 5.

The radiation doses in the various organs of these people are estimated due to previous experiments from all the measured radioactive omponents of the environments and the duration of stay at the various places.

The blood cultures are set up according to the usual methods. Microscopic scoring showed till now some acentric fragments, very few dicentrics and no rings.

5.0099, WHOLE BODY COUNTING OF POPULATION LIVING IN AREAS OF HIGH NATURAL RADIOACTIVITY

T.L. CULLEN, Pontificia Univ. Catolica, *Rio De Janeiro, Brazil*

The human population living in an area with gamma radiation levels approximately ten times normal is being studied for possible biological effects.

5. RADIATION

As part of the dosimetric study, a whole body counter was built and improved. Its calibration was renewed and the MDA is 2 nCi.

Of the dozen people thus far measured from the active area approximately half have measurable body burdens.

SUPPORTED BY Intl. Atomic Energy Agency - Austria

5.0100, A STUDY OF NATURAL RADIOACTIVITY IN BRAZIL
T.L. CULLEN, Pontificia Univ. Catolica, *Rio De Janeiro, Brazil* (AT(30-1)-2577)

Brazilian regions of high natural radioactivity are studied to see possible biological effects of chronic low level irradiation. A gas mantle factory was surveyed for intake of thoron products by workers. 1. Guarapari is a town of 6,000 who live in intimate contact with monazite sand. External levels have been measured; food analyzed. Airborne long lived activity is being measured. Whole-body counting of residents will be continued. 2. Araxa is a radioactive farmland. Some poor residents who live off the produce of their own farm will be whole- body counted. 3. Distribution of 212 Pb will be studied in humans and animals in the gas mantle factory.

Results: The population in Guarapari receive an average of 640 in R/yr external dose. Food is clean. Daily intake of dust smaller than 2 microns is about 3 pCi of long lived activity. Rude whole-body counting shows body burdens of order of 1 nCi. Chromosomal aberration in peripherical blood is being studied by Institute of Biophysics.

The gas mantle factory has airborne concentrations of 3.4 pCi of 212 Pb. Whole-body counting, 16 hours later, shows body burden of 2.7 nCi.

SUPPORTED BY U.S. Atomic Energy Commission

5.0101, RADIOCHEMICAL AND RADIOECOLOGICAL STUDIES ON BRAZILIAN AREAS OF HIGH NATURAL RADIATION - CHROMOSOMAL ABERRATIONS SURVEY
M.A. BARCINSKI, Univ. Fed. Do Rio De Janeiro, *Rio De Janeiro, Brazil* (AT(30-1)3273)

Our project concerns chromosomal analysis in population living in Brazilian areas of high natural radiation background. Two of such areas exist in Brazil in which the high level of natural radioactivity is due to the presence of thorium and/or uranium in the soil and rocks thus providing an important material to assess the viability of using chromosomal aberration as a measure of possible biological effect of chronic exposure to relatively high doses of natural radioactivity. People from the areas under survey are selected as blood donors for chromosomal analysis, the sample of choice consisting of those living in the areas for at least 10 years and with less of 50 years of age. The control group comprises people living under normal radiation levels, with the same socio-economical and racial background as those living in the exposed areas. For chromosomal analysis we use the blood lymphocyte technique proposed by Moorhead et al with some modification. Our goal for the following year is to study 120 more cases, including 60 cases from one of the areas (Guarapari) and 60 control samples.

Results: The results until now obtained showed no statistically significant difference between Araxa group (internal irradiation) and the control group, but significant difference between Guarapari group and control. The first results may be considered definitive but the second one not due to the insufficient data available until now.

5.0102, STUDIES ON THE EFFECTS OF NEUTRON IRRADIATION ON SEEDS
M. STOILOV, Bulgarian Acad. of Agri. Sci., *Sofia, Bulgaria*

With a standard neutron irradiation facility (SNIF), which was mounted at a core distance of 46, 4cm to the reactor IRT-2000, the thermal and fast neutron flux was determined. It has been found that the neutron dose in the working volume of the facility is Dn equals 22,4 rad/s, and that one of the gamma-rays - D equals 3,6 rad/s, at a reactor power of 1000 kw.

The results obtained with measurements of the first leaf of the Himalaya barley variety show a linear growth reduction with increasing of irradiation doses (50-55 % growth reduction is observed with a dose of 1000 rad). It deserves to be noted that a certain postirradiation effect after a 30 days storage of the irradiated seeds has been observed in air as well as in nitrogen stored seeds. No significant differences between different temperatures of storage have been observed.

However, in relation to chromosomal aberrations the differences are considerable. Thus when seeds are stored at -5 degrees the percentage of chromosomal aberrations decreases by 4-10 % (as dependent of doses) and at plus 20 degrees it increases by 3-5 %.

5.0105, REMOVING RADIOACTIVE FALLOUT FROM VEGETABLES AND FRUITS DURING PROCESSING
J.W. RALLS, Natl. Canners Association, *Berkeley, California* 94710 (W3-4-87(C))

OBJECTIVE: Investigate removal of external and internal radioactive materials from vegetables and fruits during processing.

APPROACH: Simulate fallout on growing fruits and vegetables. Differentiate between external and internal radioactive contamination. Evaluate washing, peeling and other processing steps for effectiveness in removing external fallout. Conduct similar studies on vegetables and fruits grown in soils spiked with strontium and cesium. Determine distribution of these elements within edible parts of vegetables and fruits.

PROGRESS: Raw potatoes grown in soil contaminated with radiostrontium were prepared in the form of cubes, shreds, and puree and mixed with water, shaken with ion exchange resin. From 4 to 24 percent of the radioactivity was removed from the solid fraction of the potato. Spray rinsing of strawberries removed only about 30% of external contamination with radiostrontium and 12% of internal contamination. However, when strawberries were blended, diluted with an equal volume of water, and centrifuged, and the supernatant treated with carbonate to precipitate Sr and Ca, 97% of the radioactivity was removed and 43% of the strawberry material was recovered. There was a 27% loss of ascorbic acid. The final product had a salty taste but it should be possible to overcome this by further treatment of the liquid with ion exchange resins.

5.0106, BEHAVIOR AND EFFECTS OF RADIONUCLIDES IN SOILS AND PLANTS (NEW TITLE)
K.L. BABCOCK, Univ. of California, School of Agriculture, *Berkeley, California* 94720 (AT(04-3)34-PROJ.023)

1) Study of the movement of 85Sr, 137Cs and 106Ru in crop plants in the greenhouse. 2) Study of the movement of 89Sr in dwarf pea and the external concentrations which cause radiation damage in the greenhouse. Microscopic examination of damaged tissue. Additional work on damage by 32P. 3) Field studies of beta radiation damage to crop plants by 90Y and associated dosimetry.

Results to date: 1. 89Sr experiments with dwarf pea have not resulted in damage when presented with the same levels of radioactivity as 32P which did produce damage. Microscopic examination of the tissue is in progress. 2. Wheat, lettuce, and corn crops have been contaminated with high levels of 90Y and instrumented with dosimeters in the field. Results are being evaluated.

5.0107, RADIATION STUDIES ON CELL POPULATIONS

H.J. BURKI, Univ. of California, Lawrence Radiation Laboratory, *Berkeley*, *California* 94720 (W-7405-ENG-48)

The purpose of this program is to study the kinetics of normal and tumor cell populations and radiobiological action of ionizing radiations. The results are of potential interest to radiation therapy of cancer and to health protection against radioisotopes.

Several years of studies with lymphoma ascites tumors on the relative biological effectiveness of fast charged particles and of pions were brought to conclusion.

Results: Ascites tumor cells are much more sensitive to high LET radiations than low LET, and the multihit survival curves become single- hit type. Young inocula of ascites cells grow experimentally in the host animal and are well oxygenated. After several days, cell proliferation slows and the cells become anoxic; radiation sensitivity exhibits corresponding changes. The radiation sensitivity of hamster kidney cells in culture shows variation with ploidy. The biological effects of the 900-MeV helium ions were measured along their ionization curve.

5.0108, STUDIES OF TRANSURANIC ELEMENTS AND OTHER RADIOACTIVE BONE-SEEKERS

P.W. DURBIN, Univ. of California, Lawrence Radiation Laboratory, *Berkeley*, *California* 94720 (W-7405-ENG-48)

The aim of this project is the elucidation of the physiological mechanisms of accumulation, translocation, retention, and elimination of the transuranic elements and other radioactive bone-seeking nuclides, the mechanisms of bone resorption and renewal, and the effects of age on these phenomena. This project has some important research by-products in the areas of bone growth and senescence, mineral metabolism, bone physiology, and bone disease.

Results: Data has been collected and some annalysis has been done on metabolic and autoradiographic studies with 241Am and 249Cf; mineral metabolism of the female Charles River-CD rat; 90Sr kinetics in primates; induction of tumors in rats by 211At; growth, maturation, aNd senescence of the female Charles River-CD rat; balance studies with human infants.

5.0109, PROTECTION FROM LONG-TERM EFFECTS OF IRRADIATION

H.B. JONES, Univ. of California, Lawrence Radiation Laboratory, *Berkeley*, *California* 94720 (W-7405-ENG-48)

An evaluation of the long-term effects of radiation and the degree to which they may be influenced by variation of conditions of radiation exposure, such as total exposure, dose rate, age of animals at exposure, etc., and the possible physiologic magnification or attenuation of these long-term effects by metabolic supplements.

An immediate aim of this research is to obtain new dose-cancer (or other pathologic) response data which will aid in the interpretation of radiation effects in the exposure range approaching natural background. Comparison of the dose-response relationship to those of chemical carcinogens is helpful in the study of additive and protective effects in carcinogenesis.

Results: Lung tumors have been induced in mice by administration of various dose schedules of urethane. We found the following: tumor yield is decreased when total dose is fractionated rather than given as one large dose; with a dose of 1.0 mg/g pathogen-free animals get fewer tumors than do those deliberately exposed to Pseudomonas; the effect of thymectomy of the yield of urethane-induced tumors indicates that the immune system plays a considerable role in genesis of tumors.

5.0110, BIOCHEMICAL AND PHYSIOLOGICAL RESPONSE TO IRRADIATION - RETICULOENDOTHELIAL SYSTEM STUDIES

H.B. JONES, Univ. of California, Lawrence Radiation Laboratory, *Berkeley*, *California* 94720 (W-7405-ENG-48)

Studies of the biochemical and physiological nature of radiation damage and of mammalian cell population dynamics and physiological function under normal and abnormal conditions. In our previous studies on the kinetics of phagocytosis, we established the presence in plasma of a clumping factor that causes colloidal carbon to agglomerate. It was suggested that this agglomeration may be an important step in the phagocytic process. Further studies have shown the agglomerating activity to be heightened by the addition of heparin 'in vitro.' This observation is interesting in light of information cited by Filkins and DiLuzio that large doses of heparin can produce marked increases in the rate of clearance of colloidal carbon. Furthermore, we have observed dog plasma to be very much more active in agglomerating the carbon than either mouse or guinea pig plasma (there may be a correspondence between this observation and the difficulty encountered by others in attempting to produce a carbon blockage in the dog). Plasma in all cases was more active than serum; this activity decreased progressively with storage time in the frozen state; and, while plasma activity was always greater than serum, the serum activity was always considerable.

Results: We have investigated the influence of multiple injections of carbon on colloidal gold and colloidal chromic phosphate. When two injections of carbon were given one hour apart and one hour prior to the gold or chromic phosphate, the gold disappearance rate was reduced to one seventh normal and the chromic phosphate to one third of normal, and very profound changes were produced in the distribution of the colloids in the body.

5.0111, BIOCHEMISTRY AND PHYSIOLOGICAL RESPONSE TO IRRADIATION--RADIOSENSITIVITY OF LYMPHOCYTES

H.B. JONES, Univ. of California, Lawrence Radiation Laboratory, *Berkeley*, *California* 94720 (W-7405-ENG-48)

Our interest in the physiology of lymphocytes and especially in their high radio-sensitivity has continued. We observed some time ago that mice treated with actinomycin-D (act-D) suffered a rapid involution of lymphoid tissue. It seemed possible that lymphocytes were especially sensitive to interference with DNA dependent RNA synthesis and that this might be a clue to the biochemical lesion leading to radiation-induced interphase death. The test system has been in vitro suspension of rat thymocytes. Cell viability was determined by eosin exclusion or by the measurement of residual extractable potassium in the cells. In this 'in vitro' system cell survival was affected only by high concentration of act-D. Act-D has been shown by Elkind and others to be a radiation sensitizing agent for tissue culture cells; it has been considered to inhibit repair.

Results: Experiments to date have yielded results that are entirely opposite to our expectations. Thymocytes treated with act-D before exposure to radiation demonstrated a very marked increase in survival compared with other irradiated cells. Radiation protection was proportional to act-D concentration in the range of 0.1 to 5 micrograms per ml. Addition of act-D in the first 4 hours after radiation also resulted in increased survival, the greatest protection being observed when act-D was added immediately after irradiation.

5.0112, METABOLIC WARD

J.H. LAWRENCE, Univ. of California, Lawrence Radiation Laboratory, *Berkeley*, *California* 94720 (W-7405-ENG-48)

5. RADIATION

The Metabolic Ward is a small hospital unit located at Cowell Memorial Hospital of the University of California containing a maximum of fifteen beds and associated laboratory space. It provides hospitalization facilities for patients, both normal and in various disease states, who because of either illness or the complexity of the studies desired, cannot be studied on an ambulatory basis. In addition to its own clinical laboratory, the Metabolic Ward provides space for those basic investigations which are closely allied to the clinical program.

The Metabolic Ward further provides facilities for reversed isolation designed for use in radiation injury where there might be suppression of bone marrow and immune mechanisms. A principal purpose for the maintenance of this small hospital unit is to keep in a readiness-state, hospital facilities for occupationsl disaster care involving radiation contamination.

Results: A detailed report of the metabolic changes observed before and after heavy-particle therapy in acromegaly was presented at the Royal College of Physician in London. Preliminary studies of the diabetes of acromegaly indicate that hydrocortisone and other glucocorticoids will suppress growth hormone levels, but at doses that are excessive. Comprehensive analysis of excretion of urinary steroids in patients with Cushing's disease who have been selected for heavy- particle pituitary irradiation has demonstrated that the competitive protein-binding assay using C-14 labelled cortisol is more specific than the fluorometric assay in plasma.

5.0113, RADIOLOGICAL PHYSICS

H. MACCABBEE, Univ. of California, Lawrence Radiation Laboratory, *Berkeley, California* 94720 (W-7405-ENG-48)

The object of this study is a better understanding of the physical interactions of ionizing radiations and matter, particularly constituents of biological tissue. Types, properties, and distribution of secondary particles and excitations are of special interest. The quantitative relationship of primary physical interactions to eventual biological events is studied by the aid of mathematical models.

We are constructing a heavy-ion microprobe which should give important information on the energy loss of relatively slow heavy particles and on the yield of secondary ions, electrons, and X rays. We have started to develop a new tool. Laminar proton radiography--for diagnostic radiology, based on physical properties of heavy particles.

Results: A theoretical study was completed for estimation of the yield of secondary particles by stripping reactions in ion beams of kinetic energy of up to several hundred MeV. These calculations give upper limits to the contribution of secondaries to dose and LET distributions of a beam of particles, and also yield estimates for exit doses caused by secondaries. The theoretical model was compared to experimental observations in a 900-MeV helium-ion beam, and satisfactory agreement was reached. Both of the above models were utilized to estimate depth-dose characteristics for future heavy-ion beams.

5.0114, ELECTRICAL AND RADIATION STUDIES ON NEURAL ACTIVITIES IN CULTURE AND IN THE INTACT ORGANISM

A.M. MAMOON, Univ. of California, Lawrence Radiation Laboratory, *Berkeley, California* 94720 (W-7405-ENG-48)

Radiations have a profound effect on the nervous system which is different from their effect on proliferating cell populations. The complexity of nervous structures, the chronic nature of the effects, and our general ignorance of how the brain functions make this a very important area to study.

Explants and cultures of mammalian nervous tissue allow detailed biophysical studies at the single-cell level, thus allowing quantitative studies of some of the basic properties of neuronal and glial cells. Currently work proceeds on the following problems: dynamics of neuronal cell culture, spontaneous electrical activity in neurons, cell-to-cell communication, morphological and functional effects of radiation, and development and differentiation.

In the intact animal the special methods of study usually involve production of radiation lesions available at the Laboratory. Heavy-ion beams allow production of a variety of local lesions in the nervous system, which are devoid of the trauma that is usually present when surgical lesions are made.

Results: We have maintained cerebellar and midbrain explants from 1 to 5 day old rats routinely for periods of six to eight weeks. A technique was developed which permits detailed studies with active two- dimensional neural nets, in which spontaneous electrical and biochemical activity has been observed. A 3,000-rad dose at the time of explanation nearly completely eliminates new myelinization, a dose-effect curve shows delay and decrease in myelin formation beginning at about 400 rad.

5.0115, CELLULAR AND SUBCELLULAR BIOPHYSICS--HEMATOPOIETIC STUDIES

H.C. MEL, Univ. of California, Lawrence Radiation Laboratory, *Berkeley, California* 94720 (W-7405-ENG-48)

Great complexity and heterogeneity is characteristic of biological mixtures. Detailed knowledge of this heterogeneity and eventual control over it are of fundamental importance in problems of cellular change and development (e.g.in erythropoiesis), of immunology (including tissue transplantation), of fertility, of carcinogenesis, and of radiation action. This project is concerned with the physical properties of cells, organelles, and molecules in complex biological mixtures, and the relationship of these properties to the biology of the particles. In continuation of work investigating relationships between bone and regeneration marrow, cells other than endosteal lining cells (previously ruled out by experiment) are being sought as prime initiating cells for marrow regeneration following local surgical depopulation.

Results: In recent rabbit work, a new cell fraction has been obtained which is highly enriched in the large primitive cells normally resident in and confined to the Haversian canals.

5.0116, SEDIMENTATION AND ELECTROPHORETIC STUDIES ON PARTICLE MIXTURES INVOLVED IN SEPARATE BIOLOGICAL AND PHYSICAL STUDIES

H.C. MEL, Univ. of California, Lawrence Radiation Laboratory, *Berkeley, California* 94720 (W-7045-ENG-48)

Great complexity and heterogeneity is characteristic of biological mixtures. Detailed knowledge of this heterogeneity and eventual control over it are of fundamental importance in problems of cellular change and development (e.g. in erythropoiesis), of immunology (including tissue transplantation), of fertility, of carcinogenesis, and of radiation action. This project is concerned with the physical properties of cells, organelles, and molecules in complex biological mixtures, and the relationship of these properties to the biology of the particles. Separated fractions of isolated mammalian (Chinese hamster) metaphase chromosomes become available in preparative scale permitting direct chemical and other investigations on subportions of the total karyotype. Following extraction with cold 10% TCA, relative DNA content was measured by the diphenylamine method.

Results: The amount of DNA per average chromosome per fraction follows a pattern generally similar to that for the average size of the chromosome in the fraction but some distinctive differences have been found in 'linear DNA density' between the fractions. Sedimentation coefficients were also measured for the population (and fractions) and found to be in the range Sw, 20 equals 0.05 to 0.48 megasvedbergs.

5.0117, STUDIES ON HAZARDS OF THE TRANSPLUTONIUM ELEMENTS

H.G. PARKER, Univ. of California, Lawrence Radiation Laboratory, *Berkeley, California* 94720 (W-7405-ENG-48)

The project is concerned with research on the hazards of transplutonium elements with particular attention to an evalua-

tion of distribution and excretion; and with hazards and therapy in the event of acute exposures to transplutonium elements by inhalation or from wounds. The development of a Si(Li) wound counter and of a routine for actinide wound analysis is almost complete. The animal whole-body counter has been completed and checked out for ordinary gamma counting of animals. The device is presently being adapted for prompt gamma coincidence counting of 252 Cf, for quantitation of Cf in the presence of its daughters and impurities, and for pilot experiments with measurement of prompt gammas from neutron-induced fission of 239 Pu in biology. Pilot studies have been continued with the use of saline aerosols for removal of lung burdens in rats, using a 195 Au colloid.

Results: Standardization of wound counter completed; wound analysis routine checked out. A monkey injected intratracheally with 195 Au colloid has provided a crude movie of time-lapse Anger scintillation camera pictures, that present visually, for the first time, the sequence of elimination of a portion of the lung burden of insoluble particulates, and its travel through the gut.

5.0118, STUDY OF RADIONUCLIDE EFFECTS ON PLANT GROWTH - WITH SPECIAL REGARD TO PLANT DAMAGE CAUSED BY IONIZING RADIATION

R.K. SCHULTZ, Univ. of California, Agricultural Experiment Sta., *Berkeley, California* 94720 (CA-B0-SPN-2408)

OBJECTIVE: Determine the scope and magnitude of the deleterious effects on plants which may be brought about by exposure to ionizing radiation of beta emitting radionuclides. Anatomical changes in plants which may be induced will be investigated at both the macroscopic and microscopic scale.

APPROACH: A properly vented plant growth chamber and facilities for safe handling of highly contaminated soils and plants will be installed at Camp Parks. This laboratory will be used for studying the effect of ionizing radiation on plant growth where this radiation arises from beta emitting radioisotopes. Plants will be exposed to this radiation by way of foliage and soil contamination. The effects of internal emitters and external exposure will be studied.

PROGRESS: Previous work of this project has dealt with effects of beta emitting radionuclides to plants when applied to foliage by immersion in water soluble Y. Dosimetry has been estimated by determination of mu/in on leaf surfaces. All previous experiments have been carried out in controlled environment chambers. The work of the past year has moved into 3 new areas. The plants have been exposed to insoluble Y fused on 88 to 177 micron sand (synthetic radioactive fallout), a new method of beta radiation dosimetry employing thermoluminescent CaF(2):Mn is under development, and a field experiment has been carried out. The first experiments using the synthetic fallout were carried out in a plant growth chamber. The radioactive sand was applied to the foliage of wheat and lettuce plants and the soil surface by entraining this very fine sand in an airstream and dropping the sand (fallout) 10 feet on to the foliage. From this work it was determined that deleterious effects occurred when the Y exceeded 17 millicuries per square foot for the lettuce crop and when the Y exceeded 5 millicuries per square foot in the case of the wheat crop. From these plant growth chamber results field experiments were designed and the new dosimetry methods are to be utilized. Results from the field experiments and new dosimetry techniques are currently under evaluation.

5.0120, ELECTROPHYSIOLOGICAL AND BIOCHEMICAL STUDIES OF THE EFFECTS OF RADIATION ON BRAIN ACTIVITY AND DEVELOPMENT

P.S. TIMIRAS, Univ. of California, Graduate School, *Berkeley, California* 94720 (AT(04-3)34,082)

Our most recent research efforts have established that neurotransmission, an important property of CNS functional activity, is markedly altered by X-radiation. Changes in neurotransmission may underlie the changes previously observed in the electrophysiological activity of the brain of irradiated rats. Accordingly, our principal efforts during this year will be directed to the study of the effects of X-radiation on neurotransmitter function, and will attempt to elucidate 1) the mechanisms of specific action of X-radiation on neurotransmission, 2) the age and structural specificity of the effects observed, and dose- age relationships.

As in our previous studies the experimental animal will be the rat at various stages of post-natal development. To elucidate the mechanism of action of X-radiation on neurotransmission, we shall explore the effects of X-radiation in brain synaptosomal preparations. Synaptosomes as well as other subcellular fractions will be studied for their content of ACh and the activity of the enzymes associated with ACh metabolism, as well as the enzyme Na K ATPase. Synaptosomes are useful in studying mechanisms of synthesis, storage and release of neurotransmitters and, therefore, the effects of X-radiation thereon. Dose-age relationships and CNS structural specificity will be investigated primarily with respect to alterations in cholinergic transmission. In addition to establishing the minimum dose required to effect these changes, we will include studies of dose-rate dependence and of acute versus prolonged radiation exposure at various stages of CNS development with a view to the radiation exposures received by human infants.

X-radiation at doses comparable to those known to induce functional alterations in the rat central nervous system also induces alterations in neurotransmission. The cholinergic enzymes, choline acetyltransferase and acetylcholinesterase, and amino acids with putative neurotransmitter function are altered by X-radiation. These alterations vary depending upon the age of the animal and the specific CNS structure under study.

SUPPORTED BY U.S. Atomic Energy Commission

5.0121, MAMMALIAN STUDIES WITH ACCELERATORS: INVESTIGATIONS WITH LARGE ANIMALS

C.A. TOBIAS, Univ. of California, Lawrence Radiation Laboratory, *Berkeley, California* 94720 (W-7405-ENG-48)

A study on the effects of simulated solar flare radiation on the squirrel monkey was completed and a report is being printed. This study was done in cooperation with the Navel Aerospace Medical Institute at Pensacola, Florida. Twenty-two squirrel monkeys were used. Groups of these animals were exposed to a simulated solar flare spectrum at the Berkeley 184" cyclotron. The primary objective of this study was observation of possible effects of radiation exposure on the vestibular system and the sense of equilibrium of the animals.

Results: There appeared to be two dose related modes of death. Hemotopoietic mode prevails at high dose levels, occurring less than 30 days post-irradiation; another mode of lethality, probably the 'skin' mode occurs at periods beyond 30 days at lower dose levels. The median lethal doses delivered at 0.5 and 1.0 cm depth for 60 day survival are 237 and 185 rads, respectively. Thus, either the simulated solar flare exposure is about twice as effective as uniform dose, or the squirrel monkeys are much more sensitive to radiation than rhesus monkeys.

5.0122, THE EFFECTS OF GRAVITY COMPENSATION, RADIATION AND MAGNETIC FIELDS ON LIVING ORGANISMS

C.A. TOBIAS, Univ. of California, Lawrence Radiation Laboratory, *Berkeley, California* 94720 (W-7405-ENG-48)

5. RADIATION

These studies aim to measure possible synergistic effects between gravity compensation and radiation on developing organisms. In addition, separate investigations will study relationships between effects of ultrasonic vibrations and radiations. The results are expected to be of value in interpreting biological effects of space environment; for example, the apparent synergism obtained between radiation and weightlessness in Biosatellite II. The results may also be of value in considering the radiobiology of tumor cells.

Results: Engineering and construction of a one-dimensional clinostat has been completed. Gravity compensation is accomplished by uniform, vibration free rotation of the biological test objects, around a horizontal axis, at various angular velocities. The clinostat is housed in a lead shield and can be controllably exposed to a cesium gamma ray source for periods of many days. Air temperature and humidity control is provided, and an aerobic radiation exposure is possible.

SUPPORTED BY U.S. Atomic Energy Commission

5.0123, MAMMALIAN STUDIES WITH ACCELERATORS - RELATIONSHIP OF CELLULAR CONTROL MECHANISMS TO CARCINOGENIC EFFECT OF ACCELERATED IONS

C.A. TOBIAS, Univ. of California, Lawrence Radiation Laboratory, *Berkeley, California* 94720 (W-7405-ENG-48)

Groups of CD random bred mice have been exposed to whole-skin irradiation by accelerated helium ions at the 88' cyclotron. The penetration of the beam is accurately controlled with definite depth at 120, 220, 310, and 510 microns. In this manner, we hope to obtain some information on the participation of different tissue layers in the tumorogenic process and on the effectiveness of helium ions in inducing tumors. Work has continued in an effort to isolate a tissue specific regulatory substance (i.e., 'chalone') which presumably suppresses mitosis and thereby maintains tissue homeostasis. This study is an extension of the study of heliumn-ion carcinogenic properties in mammalian epidermis.

Results: Crude extracts of mammalian epidermis have been demonstrated to exert a mitotic inhibitory effect on human (foreskin) epidermal cells in culture. When applied complexed with adrenalin, the extract suppresses mitosis for a period of 12 to 16 hours (approximately one generation time). The extract was ineffective when applied alone or on tissue culture cells of non-epidermal origin.

5.0124, MAMMALIAN STUDIES WITH ACCELERATORS: GERMFREE RESEARCH

C.A. TOBIAS, Univ. of California, Lawrence Radiation Laboratory, *Berkeley, California* 94720 (W-7405-ENG-48)

The response of both germfree and conventional CD strain, random bred mice to a high-energy proton beam (740 MeV) has been investigated. Our initial efforts indicate an RBE of 0.97 and 1.1, respectively, for germfree and conventional mice. An important aspect of this work involves the observation of relative predominance of gastrointestinal vs. hematopoietic injury as expressed by the time distributed mortality response of charged-particle and conventional irradiated animals.

Results: Initial results suggest that, for this particular strain of both conventional and germfree mice, the propensity for gastrointestinal death observed in charged particle-irradiated animals as compared with their conventionally irradiated (Co60) counterparts does not appear to exist. The time course of mortality for both types of radiation in the dose range of about 800 to 1100 rads was essentially identical.

SUPPORTED BY U.S. Atomic Energy Commission

5.0125, THE EFFECTS OF GRAVITY COMPENSATION, RADIATION AND MAGNETIC FIELDS ON LIVING ORGANISM

C.A. TOBIAS, Univ. of California, Lawrence Radiation Laboratory, *Berkeley, California* 94720 (W-7405-ENG-48)

Our aim is to study the interaction of gravity compensation and radiation on 'Tribolium' pupae in order to obtain ground-level comparison with the results obtained in the spaceflight of Biosatellite II. During the spaceflight the effects of spaceflight factors were in an apparent synergism with radiation effects. Further studies are being made on developing eggs and pupae.

Results: Preliminary results are: the number of wing abnormalities induced in pupae by radiation appears to be slightly greater when gravity is compensated at 8 rpm than when it is not; fertilized eggs are much more radiosensitive than pupae (by a factor of approximately 4); pupae, suspended in water and exposed to ultrasonic vibrations at one megahertz, show marked effects on development, including the induction of wing abnormalities.

SUPPORTED BY U.S. Atomic Energy Commission

5.0126, MAMMALIAN STUDIES WITH ACCELERATORS - WHOLE SKIN HELIUM ION IRRADIATION STUDY

C.A. TOBIAS, Univ. of California, Lawrence Radiation Laboratory, *Berkeley, California* 94720 (W-7405-ENG-48)

Work has progressed relating the possible predisposition of animals to increased radiosensitivity to whole-body 60Co-irradiation when such exposure has been immediately preceded (in hours) by helium-ion damage limited solely to the whole skin of Swiss-Webster mice. The mortality patterns of the two radiations delivered separately are markedly different. Death from whole-body 60Co-irradiation in the mid-lethal dose region (less than 1,000 rads) occurs mainly from 9 to 17 days and is due to hemotopoietic injury. Animals irradiated with whole- body helium ions die mainly in a 22 to 42 day period post-irradiation.

Results: A helium ion dose of 770 rads to the skin sublethal in itself increases the 20-day cumulative mortality by a factor of 1.5 to 2.0. This means that almost twice as many animals died from 60Co- induced radiation injury when that injury was accompanied by radiation- induced skin damage.

5.0128, X-IRRADIATION EFFECTS OF ACUTE AND FRACTIONATED EXPOSURE IN BEAGLE DOGS

L.K. BUSTAD, Univ. of California, School of Veterinary Medicine, *Davis, California* 95616 (AT(04-3)-472)

The nature and extent of lifespan shortening, tumor incidence, and diminished reproductive capacity is being determined in beagle dogs following exposure to fractionated or acute doses of X-irradiation. These data are necessary for assessing effects of accidental radiation exposure or the exposure predicted for crews of nuclear-propelled aerospace vehicles.

A total of 360 young adult beagles were exposed to 100 or 300R administered either acutely or in 2 or 4 dose sessions at 7-, 14-, or 28-day intervals.

Exposure to 100R or 300R fractionated or acute X-radiation resulted in a life shortening of about 7% per 100R but failed to reduce reproductive capacity as measured by number and survival of pups in the first 2 litters. Tumors observed in the irradiated dogs were of the same type as those observed in the controls and with a higher frequency.

SUPPORTED BY U.S. Atomic Energy Commission

5.0129, RELATIVE EFFECTIVENESS OF X-IRRADIATION AND RADIOIODINES ON THYROID FUNCTION

L.K. BUSTAD, Univ. of California, School of Veterinary Medicine, *Davis, California* 95616 (AT(04-3)-472)

Quantitative data are being obtained on the comparative effects of X-irradiation and radio-iodine on young beagles, to deter-

mine the dose effecting functional changes in the thyroid gland. The study was designed in part to answer questions regarding the dose-effect aspects of thyroid radiation exposure of young children to diagnostic and therapeutic X-ray and to fallout in the Marshall Islands.

Clinical and biochemical studies two years after the initial exposure of beagle pups indicate that radiation-induced damage can be detected only in the animals exposed to 4500 rad. All dogs, however, appear normal.

5.0130, GERONTOLOGIC CHANGES IN BEAGLES
L.K. BUSTAD, Univ. of California, School of Veterinary Medicine, *Davis, California* 95616 (AT(04-3)-472)

Physiologic performance and efficiency are being measured to permit qualitative and quantitative evaluation of the nature and effects of radiation (emphasizing internal emitters) on aging. Body temperature, K40 content, radiographic changes, thyroid function, eye changes, skin- fold thickness, cardiovascular and pulmonary function are compared in radiated and control dogs. Response to temperature stress as a function of age will be determined in a selected number of animals. An attempt will be made to delineate the similarities to man, to construct a model for radiation-induced alterations in aging patterns. Support will be sought for a study of the ability of antioxidants to prevent some premature aging changes due to radiation and to prolong the lifespan of beagles.

Mucopolysaccharide content of costal cartilage decreased linearly, and the insoluble protein of the lens increased linearly with increasing age. Reproductive ability waned by 7 years, anestrus was extended, and fewer pups were whelped and weaned in each litter. Ovaries at 7 years manifested surface convolutions, abnormalities in subepithelial tubules, and decreased numbers of follicles, and increased numbers of microadenomas.

5.0131, CELLULAR AND CYTOGENETIC EVALUATION OF RADIATION EFFECT
L.K. BUSTAD, Univ. of California, School of Veterinary Medicine, *Davis, California* 95616 (AT(04-3)-472)

The extent of deoxyribonuclear and chromosomal damage is being determined in cells of the hematopoietic system of beagles and Marmosa mitis following X-irradiation or ingestion of 90Sr. Of particular interest is the study of animals that have developed 90Sr-induced myeloproliferative disorders, to determine the nature of the radiation- induced lesion(s) and the extent of repair. Serial bone marrow samples are obtained for determination of endogenous DNA content, RNA content, and base composition and correlation to numbers and kinds of cells present. Efficiencies of intact cells in utilizing various nucleic acid precursors are determined and compared. Priming ability of the DNA is measured in cell-free assay systems. In vitro determinations of DNA- dependent RNA synthesis will be performed.

Assay systems have been defined for measuring cellular and cell- free nucleoside and nucleotide metabolism in dog bone marrow cells. In dogs manifesting a radiation-induced myeloproliferative syndrome, the endogenous DNA per cell was 1.5 greater than that in controls although the DNA synthetic rate per cell was slighdy less and there was an abnormally high deoxypurine content. Methods of culturing and harvesting chromosomes have been adapted for the marmosa lymphocyte system to permit examination of a single specimen by light and electron microscopy.

5.0132, EFFECT OF PROLONGED LOW DOSE RATE CO60 GAMMA RAY EXPOSURE TO BEAGLES
L.K. BUSTAD, Univ. of California, School of Veterinary Medicine, *Davis, California* 95616 (AT(04-3)-472)

Whole-body gamma irradiation will be compared to irradiation from deposited Sr90 and Ra220 for effectiveness in inducing changes in the hematopoietic system of beagles. Emphasis will be given to radiation induction of neoplasia. The effect of age at exposure on the incidence of myeloproliferative disease are also important considerations to be evaluated. The study will also provide data on the relative effectiveness of low dose rates compared to equivalent doses given acutely. Beagle dogs of varying ages will be continuously exposed to Co60 gamma radiation in a Co60 field which holds 200 dogs. Dosage rates will range from 0.5R/day to 15R/day and will be compared with doses utilized in an acute radiation study as well as in a long-term study of Sr90 and Ra226 deposited internally.

The radiation exposure field is being completed and measurements have been made in the Co60 field for establishing the desired radiation exposure zones. A pilot study will begin in 1970.

5.0133, EFFECTS OF LOW-LEVEL IRRADIATION ON DEVELOPING OVARIES OF DOGS AND MONKEYS
L.K. BUSTAD, Univ. of California, School of Veterinary Medicine, *Davis, California* 95616 (AT(04-3)-472)

The nature and time of the most radiosensitive period of the developing ovary of dogs and subhuman primates is being determined by administering fractioned radiation during gestation and/or the suckling period. In earlier studies, 100R and 300R exposures to young adult female beagles failed to reduce their reproductive capacity. However, when fractioned doses totaling 200R were administered during the suckling period, sterilization occurred. Since reports have appeared indicating that adult subhuman primates are not sterilized by 5000R, it was of practical interest to extend the dog studies to the subhuman primate. Bonnet monkeys are being exposed to low doses of X-ray twice each at various periods of gestation to determine the most sensitive period of development. The data are of importance for the human population if the ovaries of women are as sensitive during early development as those of dogs and monkeys appear to be.

Sterilization and ovarian tumors were induced in female beagles by exposure to 10R X-radiation on alternate days from birth to 42 days of age. Afollicular ovaries appeared in subhuman primates exposed to 10R twice weekly during 2-5 months of gestation.

SUPPORTED BY U.S. Atomic Energy Commission

5.0134, COMPARATIVE TOXICITY OF SR90 AND RA226 IN BEAGLES
L.K. BUSTAD, Univ. of California, School of Veterinary Medicine, *Davis, California* 95616 (AT(04-3)-472)

This long-term study is designed to (a) define the hazards of chronic ingestion of Sr90 in the beagle dog and, by comparing effects to those following Ra226 exposure, permit extrapolation of the results to man, and (b) describe the mechanism and dose-response curve for Sr90 induced granulocytic leukemia and osteogenic sarcoma. Much information is available on the effects of Ra226 in man. By determining the relative toxicity and dose effect relation of Ra226 and Sr90 in the dog, a firm basis for evaluating the hazards of Sr90 to man will be obtained. The data will also be utilized by national and international councils for setting radiation exposure criteria and limits. The Sr90-induced cancers resemble those described in man and are useful models for studying the same diseases in man. Six different levels of Sr90 are fed to female beagles beginning at 21 days following conception. At weaning, the pups are placed on the same Sr90 feeding regimen as their dams until 18 months of age and are observed for their lifespan. Other beagles are injected with comparative levels of Ra226 at 14-18 months of age, simulating Ra226 exposure to young human dial painters who manifested radium toxicity. One thousand beagles are involved in the study.

Results: Strontium-90 radiation effects are seen only at the highest levels of exposure (12 or 36 muCi Sr90/day to 18 months). No granulocytic leukemia has been observed on dogs exposed to less than 1000 rads to bone marrow and no osteogenic sarcomas have been observed in dogs exposed to less than 8000 rads to bone. Following cessation of feeding, Sr90 is lost from cortical bone with a 10-15 yr half period, from trabecular bone with a 1-2 yr half period.

5.0135, KINETICS OF HEMATOPOIETIC REPOPULATION FOLLOWING IRRADIATION INJURY
J.P. LEWIS, Univ. of California, School of Medicine, *Davis, California* 95616 (AT)

The objective of these studies is to identify variations in hematopoietic recovery patterns in mice given either 1) a LD 100/30 dose of X-ray followed by a 50% protective dose of syngeneic marrow, 2) a LD 50/30 dose of irradiation, or 3) a Ld/100/30 dose of X-ray with sufficient shielding to assure 50% survival of the animals.

It is generally conceded that hematopoietic repopulation begins from stem cells. Yet in the three regimens to be studied the patterns of cellular proliferation differ considerably suggesting that in some of these regimens either the population begins from cells other than stem cells or that factors regulating the repopulation process vary from regimen to regimen. Using the hematopoietic colony technique and employing the three regimens in each experiment, various parameters of hematopoietic recovery will be investigated including the number of stem cells which provide 50% survival of animals, patterns of stem cell differentiation, rates of stem cell renewal, rate of growth of differentiated cells, patterns of recovery of peripheral blood elements, ferrokinetics, and response of recovering marrow to various humoral factors such as erythropoietin and endotoxin. These studies will be performed using CAF sub1 mice of similar sex and age to reduce variation between the experimental animals.

Results: The modal day of death of mice treated with LD 100/30 dose of irradiation followed by a 50% protective dose of syngeneic marrow is 11 days: whereas the modal day of death of mice treated by a LD 50/30 dose of irradiation is 17 days. Splenic hematopoiesis is extensive in the first regimen and nonexistent in the second (LD 50/30). Stem cell renewal in the marrow transplanted animal occurs on the 5th to 6th day and in the animal recovering from sublethal radiation has not occurred by day 7. The pattern of ferrokinetics in the marrow transplanted animals differs considerably from the sub-lethally irradiated mice.

5.0136, A SYSTEMATIC SURVEY OF THE EXCRETION OF RADIONUCLIDES
R.J. CHERTOK, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

The excretion rates of certain radionuclides will be influenced by some of the elements naturally present in the body and by elements added to the diet. This suggests an approach to the exploration of countermeasures.

Stable elements are injected intravenously into beagles and 24-hr urine samples and some serum samples are collected. The samples are analyzed by atomic absorption spectroscopy for the injected and similar elements. In some cases a radionuclide is given in a single oral dose and the rate of loss is determined by whole-body analysis. The urinary and fecal excretion rates are determined. After normal modes and rates of excretion are established, countermeasures are sought for those elements whose excretion rates are so low as to make this radionuclide potentially hazardous to man. A single dose of radionuclide is injected into rats and treatments that might be expected to enhance the excretion rate of the radionuclide are instituted. The rate of loss of the nuclide is determined by daily whole-body analysis. The tissue distribution is then determined.

Results: The study of Group IIA elements revealed only Sr and Be were excreted rapidly with no effect on the other elements and Mg caused a slight elevation in the excretion rates of Ca and Mg. In the elemental survey using radioactive isotopes, the elements studied include in order of decreasing absorption across the gut, Cs-137, Mo-99, Na-22, W-181, Zn-65, Tl-204, Fe-59, Mn-54, Hg-203, Ta-182, Pb-203, and Sn-113. A study of countermeasures for reducing the body burden of Cs- 137 revealed that of Cs, K, Rb, Diamox, Diuril, Lasix, Thyrotropin and Thyroxine, Thyroxine was the most effective.

5.0137, METABOLISM OF NUCLEAR DEBRIS IN THE DOG AND THE PIG
R.J. CHERTOK, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

From compilations of correlated data from many nuclear events there should be an emergence of generalization that will not only broaden and deepen our capabilities for evaluating the biological feasibility of proposed nuclear projects but also enable the identification of all potentially hazardous radionuclides as well as potentially hazardous devices and detonation conditions.

Field studies have been conducted with lactating domestic goats (inhalation) and Yorkshire pigs (inhalation and ingestion) which were placed in the calculated fallout pattern of some cratering events. Tissue distribution of the debris radionuclides was determined. Also nuclear debris collected from cratering events are given orally to peccary pigs (Tayassu tajacu) in a single oral dose. The animals are then analyzed daily on a solid-state detector for all the gamma-emitting radionuclides. Daily urine and feces collections are also analyzed. Tissue distribution is determined after the modes and rates of loss of the various radionuclides are determined. Similar studies have been done with debris given daily over a long period of time. Single oral doses of debris have also been given to beagles and the modes and rates of excretion of the various radionuclides have been determined.

Results: Radionuclides found to be common in several nuclear events have different rates and routes of excretion (Te-132, I-131, Ru- 103, W-187). Some of the radionuclides in the debris have also been found to behave differently biologically when given as a single isotope (Mo-99, W-181). These differences are probably due to the chemical and/or physical state of the radionuclides.

5.0138, RADIATION EFFECTS ON DIFFERENTIATION AND TISSUE CONTROL
R.L. DOBSON, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

The objective of this research is threefold: First, to identify and compare, in carefully selected contrasting biological systems, the mechanisms by which radiation affects differentiation and tissue organization; second, to relate the radiobiological effects at the molecular, cellular, and tissue levels and to collate them with actions of other comparable agents; third, to elucidate the fundamental links between these mechanisms and the urgent questions that face us in practical human radiation health - carcinogenesis, genetic effects, and derangements of tissue development. Comparative studies involve species representing differing levels of biological organization: bacteria, fungi hydroids, flatworms and vertebrates. Main interest in the long run is in low-level exposure and incorporated radionuclides.

Planarians were selected for initial study because cell differentiation and tissue reorganization are easily elicited in them. It was demonstrated that after x-irradiation animals can regenerate as readily as controls, indicating that new cell formation is not necessary for replacement of parts. The late appearance of a particular head anomaly in animals that had been surgically decapitated after irradiation, as well as in worms left intact, indicated that latent radiation damage persists in non-head cells as they differentiate, becoming manifest only after the new head has been completed. Results: In associated biochemical studies, planarian DNA has been isolated and characterized with regard to buoyant density, melting temperature and base composition. Contrary to published reports, we have found that radioactive thymidine, administered in the water, is very poorly incorporated into planarian DNA, whether the animals are regenerating or not. However, the radioactive label is readily found in association with a non-DNA, carbohydrate component that tends to accompany DNA in separations. This may give the unwary observer an erroneous impression of rapid DNA synthesis.

5.0139, SOMATIC EFFECTS OF LOW DOSE RADIATION: RADIATION, CHROMOSOMES AND HUMAN CANCER

J.W. GOFMAN, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

Objectives of this program are: 1) To characterize quantitatively the chromosome constitution of a significant number of established human cell lines of apparently unlimited life span contrasted with normal human cells; 2) To characterize quantitatively the chromosome constitution of a significant number of cells per cancer and of a significant number of human cancers of several types; 3) To ascertain (if any quantitative chromosome systematics apply to human cancer cells or to established human cell lines), whether or not low dose radiation produces cells with such alterations, and the quantitative aspects of such production. Use of atomic energy for peaceful purposes requires more knowledge of the possible effects upon man of low dose radiation delivered at a low rate. In view of the well known limitations upon direct assessment of somatic effects of low dose radiation in man, it continues to be attractive to approach this problem at the cellular level.

Until technology provides a useful direct computer-microscope interface, projected chromosomes are traced on vellums with black ink. Overlaps and touching arms are separated and idealized. These are photographed on 35mm film, electronically scanned, and the chromosomes are computer analyzed for arm lengths and centromere position. Results are statistically analyzed with a computer program designed to isolate significant numbers and ratios of chromosome groups.

Results: Standard tissue culture techniques are used to provide material for this program. 17 established human cell lines and 11 fresh human cancer specimens have now been karyotyped and all show a marked excess of E16 chromosomes per cell, both absolute and relative to other chromosome classes (1834 normal human control karyotypes have been done). Experiments are currently underway to determine long term effects on chromosomes from acute radiation doses of 500R and chronic doses of 100 mr/hr and less on human fibroblast cultures until persistent viable chromosomal aberrations are observed.

SUPPORTED BY U.S. Atomic Energy Commission

5.0140, EFFECTS OF LOW DOSES OF IONIZING RADIATION ON NUCLEIC ACID STRUCTURE AND FUNCTION

F.T. HATCH, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

Objective: To determine, with primarily biochemical and physicochemical techniques, radiation effects on natural nucleic acids in vivo and in vitro and on synthetic polynucleotides in vitro. Particular emphasis is placed on tritium irradiation. Background: DNA is generally believed to be the cellular constituent most sensitive to radiation damage. Phenomena, e.g., chromosome defects, delayed cell division and cell death, have been observed at fairly low doses. Effects on more easily understood biochemical systems, e.g., DNA and enzymes, have generally required much higher doses for demonstration. Procedures: Liver DNA is obtained from kangaroo rats living in a tritiated environment at a low radiation level. Polynucleotides containing tritium-labeled nucleotides are enzymatically synthesized. These products are examined by density gradient centrifugation, ultraviolet spectroscopy and functional enzymatic assays.

Results: The kangaroo rat has two 'satellite' DNA's in density gradients which are more abundant than in any other reported species. Low dose chronic irradiation appears to stimulate an increase in the amounts of these satellites; however, further elucidation of confounding variables is required before drawing firm conclusions. Intramolecular tritium appears more effective than extramolecular (solvent) tritium in damaging the synthetic polynucleotide.

5.0141, METABOLISM OF HYDROGEN ISOTOPES

W.L. ROBISON, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

This research effort is designed to determine the extent to which tritium is incorporated into various organic components as a result of long-term and short-term environmental exposure which would label foodstuffs as well as water. This information will aid in determining whether or not isotopic concentration mechanisms exist in organic compartments relative to the body water compartment as a result of intake of tritiated organics or tritiated water. It can then be determined whether models based on turnover rates of tritium in water alone are adequate to predict hazards from nuclear releases. Similar data will be obtained for deuterium and it will serve as a reference level for interpreting the tritium data. Certain fractionation mechanisms have been observed for tritium and deuterium. These are very isolated cases and the general effect is very much in question. Tritium and deuterium concentrations will be determined in the free water and combustion water of various organs of humans who have been exposed to natural environmental tritium concentrations. Analysis of available foodstuffs will also be carried out. Samples from sites of elevated tritium exposure involving complex ecosystems will also be analyzed to determine the tritium concentrations in the two compartments. Laboratory experiments involving various animals will also be initiated to determine the tritium distribution as a result of available tritiated organics.

Results: These experiments have just been initiated and only very preliminary data have been obtained.

5.0142, BIOLOGICAL CONTROL PROCESSES AND RADIATION

R.N. STUART, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

Our objective is first to develop mathematical models and related in vivo techniques which will allow determination of the binding constants, reaction rates and reactant concentrations that define the regulation behavior of the lac operon in E. coli. We will then use this methodology to determine the effects of radiation and related perturbations on each of these parameters individually. This approach should permit a precise definition of the susceptibility to radiation of each aspect of transcription level control of protein synthesis in bacteria. It will also provide valuable comparisons with the results of in vitro characterizations of the same system. The value of both aims rests on the great biological importance and ubiquity of protein synthesis control, including its vulnerabilities and pathologies. Our approach primarily involves kinetic studies of the control of beta- galactosidase synthesis in several strains of E. coli possessing both wild type and mutated lac repressors, together with a coordinated theoretical effort to develop mathematical models that can predict, exploit and direct the experimental work. Experiments using a lac transducing phage to manipulate the repressor concentration are in the beginning stages.

Results: Theoretical work, including a simple statistical model to accommodate low average numbers of repressor molecules per cell, is largely complete and our procedures for characterizing the effect of inducer on repressor-operator binding are finished. An experimental system in which all but one of the parameters for the repressor-operator interaction can be separately assayed is under final study and is apparently successful.

5.0143, THE BIOLOGICAL EFFECTS OF LOW DOSAGE RADIATION

A.R. TAMPLIN, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

5. RADIATION

The major outstanding question with respect to the peaceful uses of nuclear energy concerns the biological effects of low dosage and low dose rate radiation. Over the past 25 years a very considerable amount of experimental work has been conducted in this area. Moreover, there have been numerous theoretical papers published on this subject. Nevertheless, the problem has remained as a major area of controversy. The purpose of this program is to bring together and analyze the existing worldwide literature pertinent to the somatic and genetic effects of radiation and to integrate this inforation into a cohesive and supportable, practical state-of-the-art ability to predict the biological effects of radiation. The objective would be to pinpoint the areas of major uncertainty and to suggest experimental approach to resolving these uncertainties.

Results: During this fiscal year we have continued our study on the lung hazard associated with highly radioactive particles deposited in the deep respiratory zone. A report on this subject is now in preparation. In addition, during this fiscal year we have brought together and analyzed that data concerning the induction of cancer in man by radiation. We have prepared a number of reports on this subject.

5.0144, PROTEIN SYNTHESIS DURING EARLY DEVELOPMENT OF THE SEA URCHIN EMBRYO

H. TIMOURIAN, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

To determine extent of damage to mechanism of protein synthesis by small doses of radionuclides and by stable ions used to eliminate them. Protein synthesis during the early hours of development of the sea urchin is ideally suited, for there is no dependence on genetic material and any effect can be completely divorced from those on nuclear genome. Protein synthesis in embryos is studied by incorporation of radioactive amino acids into protein and ribosome fractions.

Results: Some of the changes in the egg's capacity for protein synthesis at the time of fertilization have been characterized at subcellular levels. These changes include changes in the activity of ribosomes, the soluble enzymes, and membrane characteristics.

5.0145, NEUROPHYSIOLOGICAL AND BEHAVIORAL EFFECTS ASSOCIATED WITH THE INCIDENTAL IRRADIATION OF NORMAL HUMANS

R.S. BOSWELL, U.S. Veterans Administration, Hospital, *Long Beach, California* 90801

The effects of daily Cobalt-60 irradiation on sensory detection of radiation, visual perception, and simple motor performance were investigated in 'normal' human subjects during actual and sham irradiation of the apparently normal brain incidental to radiotherapy. The experiments were carried out in both dark and light adapted persons and it was found that: (a) sensory detection of radiation by humans is not reliable when the phosphene effect is eliminated; (b) visual perception is differentially affected by radiation as a function of the dark-light adaptation state of the retina; and (c) simple motor performance appears to be impaired when central portions of the brain receive about 50 rad.

In addition to these experiments, complex motor performance in multiportal pelvic-irradiated patients was assessed using a modified target gun. The results suggested no reliable post-treatment effects of Cobalt-60 irradiation on complex motor performance under the specified test conditions.

SUPPORTED BY U.S. Veterans Administration

5.0146, RADIATION INDUCED RENAL TUMORS - ELECTRON MICROSCOPE STUDIES

V.J. ROSEN, U.S. Veterans Administration, Center, *Los Angeles, California* 90073

Since submission of the last report, mice up to 18 months of age have been sacrificed and well formed cystic tubular adenomas are now being studied. In addition, surprising changes in aged intact controls are now being seen and appear to be unrelated to the neoplastic process. In the tumors, a variation in ultrastructure from one cell to another is noted. Some tumor cells show large numbers of mitochondria, others show vesicular cytoplasm with sparse organelles, and most show striking changes in the cell surface with loss of microvilli. In the last sacrifice group (18 months), regressive changes apparently related to ischemia are present. The ischemic alterations are more pronounced in the irradiated uninephrectomized animals which also have a more advanced glomerulosclerosis. Many of these findings are now being reported in a chapter on Radiation Carcinogenesis to be published in the forthcoming year. The material reported here is basically a survey of selected samples. Numerous additional sections must be cut to try and assemble an evolutionary sequence in the development of the tumors. This should require at least one more year of study.

5.0147, EFFECTS OF NUCLEAR TESTING ON VASCULAR PLANT AND RODENT POPULATIONS, NEVADA TEST SITE, NYE COUNTY, NEVADA

J.C. BEATLEY, Univ. of California, Lab. of Nucl. Med. Rad. Biol., *Los Angeles, California* 90024 (AT(04-1)GEN-12)

From comparisons of parameters of interest in systems disturbed by nuclear testing (or other origin) at the Nevada Test Site, with the expression of the same parameters in undisturbed systems, certain evaluations of the effects of weapons and other testing on plant species, communities, and rodent populations are in progress. Near completion is a comparison of certain reproductive characters (carpel weight, percent seed germination, and seedling weight under growth chamber conditions) in Larrea divaricata Cav. (Creosote-bush) in 30 sampled irradiated and nonirradiated populations, in relation to environmental variables including gamma radiation, on each of the sampling sites and each of the years 1962-65.

All sampling and data processing are completed, and regression analyses of the variables being compared in the Larrea study are in progress.

5.0148, VASCULAR PLANT AND RODENT PARAMETERS IN 68 MOJAVE AND GREAT BASIN ECOSYSTEMS, NEVADA TEST SITE, SOUTHERN NEVADA, 1962-70

J.C. BEATLEY, Univ. of California, Lab. of Nucl. Med. Rad. Biol., *Los Angeles, California* 90024 (AT(04-1)GEN-12)

Toward the ojective of assessment of the effects of nuclear testing on native plant and animal populations of the Nevada Test Site, 68 ecosystems were selected over a 1000 square mile area in the spring of 1962. Definition of certain plant and animal parameters which might enable the distinguishing of changes due to testing from changes due to other causes, have been accomplished in the years since that time, to the extent that manpower has permitted. On all sites, for shrubs (and trees at the higher elevations), herbaceous perennials, winter annuals, and summer annuals, quantitative data have been collected from 1 to 8 consecutive years appropriate to the objectives, and rodent censusing conducted five consecutive seasons. Environmental measuurements were made concurrently on each site (see 'Precipitation, Air Temperatures, Soil Moisture, and Gamma Radiation' project).

SUPPORTED BY U.S. Atomic Energy Commission

5.0149, LATE EFFECTS OF RADIATION IN MAMMALS

L.R. BENNETT, Univ. of California, Lab. of Nucl. Med. Rad. Biol., *Los Angeles, California* 90024 (AT(04-1)GEN-12)

Currently the research of this section is concerned with: (1) The mechanisms, at both the physiological and molecular biological level, of the life shortening process following total body irradiation. This is a gradual change in emphasis from earlier studies which were primarily concerned with the pathology and statistics of life shortening, disease incidence, and clinical course. (2) The consequences of partial body irradiation which have not

been as clearly defined either as to pathology or as to life shortening. The study of partial body irradiation represents an area of growing importance since this type of irradiation results from certain toxicological and industrial exposures as well as improperly administered diagnostic x-ray. This study is of increasing importance in nuclear medicine, radiation therapy, and organ transplantation.

Results: Immuno-supression with I-131 tagged antigen in amounts necessary to protect skin transplants has failed to show life shortening or other deleterious effects.

SUPPORTED BY U.S. Atomic Energy Commission

5.0150, EFFECT OF IONIZING RADIATION ON DIVISION-RELATED MACROMOLECULES

J.E. BYFIELD, Univ. of California, Lab. of Nucl. Med. Rad. Biol., *Los Angeles, California* 90024 (AT(04-1)GEN-12)

The overall goal of this investigation is to determine the acute effects of ionizing radiation on the expression of those gene sequences which control cytokinesis. Cytokinesis is used here to define the physical aspects of cell division (i.e., the production of two daughter cells from a single, mature, fully replicated cell). Past research has defined the mechanism by which the ciliated protozoan Tetrahymena pyriformis becomes synchronized following a series of cyclical temperature shifts. The results indicate that the synchronized Tetrahymena population appears almost ideal for an in depth study of the effects of ionizing radiation on the replication and expression of the DNA sequences coding for cell division. Beyond the obvious relevance to radiation biologists of the effects of radiation on cell division, it is noteworthy to point out that the expression of the gene sequences for cell division in Tetrahymena also offers an opportunity to study the effects of radiation on a complete, integrated entity of cellular differentiation. Unlike other cells, ciliates like Tetrahymena begin the process of cell division by the organization of the second oral apparatus. The formation of this large structure follows a regular sequence in time and can be followed accurately by both silver staining and by electron microscopy. Our previous investigations have led to a considerable understanding of the biochemical events controlling this step in cellular differentiation; the additive benefit of having a controllable morphogenetic sequence to follow makes this cell system particularly useful. It is our object over the next two years to initiate an investigation of the effects of radiation on each step in this complex developmental sequence. Eventually, we hope to explore the control of replication of the genes involved, their transcription and translation, and the ultimate formation of the quarternary structures they code for, including the oral apparatus and cleavage furrow.

5.0151, LYMPHOCYTE SIZE AND DENSITY DISTRIBUTIONS

B. CASSEN, Univ. of California, Lab. of Nucl. Med. Rad. Biol., *Los Angeles, California* 90024 (AT(04-1)GEN-12)

Accurate determinations of some of the physical properties of viable cells in suspension enables the effects of radiation in vitro and in vivo, the effects of surface active agents and the effects of hormones on these physical properties to be ascertained. We have perfected methods for rapidly determining size distributions by the Coulter aperture principle and for rapidly determining density distributions by equilibrium centrifugation in a precise linear bovine serum albumin gradient. Size distributions can be determined on individual density fractions. These methods have been and are being applied to measurements on human leukocytes, especially lymphocytes, in health and in leukemia. Radiation effects, especially at low doses (100-700 rad) are being determined in rabbit blood. They have been applied to measurements on the size and density of fetal and post natal erythrocytes in maturing mice. These measurements are part of a continuing project.

Results: One important generalization that has appeared to have emerged is that in all series of cells so far studied, the larger cells in an identifiable series are less dense than the smaller cells. Usually a smooth monotonic curve is obtained when density is plotted against size.

SUPPORTED BY U.S. Atomic Energy Commission

5.0152, BIOCHEMICAL EFFECTS OF IONIZING RADIATION ON BRAIN CELLS IN CULTURE

J. DEVELLIS, Univ. of California, Lab. of Nucl. Med. Rad. Biol., *Los Angeles, California* 90024 (AT(04-1)GEN-12)

Neuronal and glial cell lines have been established from brain tumors in culture. The radiation effects on glial and neuronal differentiation previously observed in vivo can now be studied under controlled physical and chemical conditions. The parameters studied include: hormonal induction of glycerolphosphate dehydrogenase and lactate dehydrogenase; synthesis and degradation of DNA, RNA, proteins and myelin lipids (total, fractions, and individual compounds). Changes on nucleic acids are being investigated using polyacrylamide gel electrophoresis and hybridization techniques.

Results: Much higher doses of ionizing radiation were required to obtain inhibition of enzyme inductions in vitro than in vivo. When glial cells were grown in the presence of the radiosensitizer, 5- bromodeoxyuridine, inhibition of protein synthesis was obtained with much lower radiation doses. Greater repair and recovery appears to take place in vitro than in vivo.

5.0153, A SURVEY OF CHEMICAL AND PHYSICAL PROPERTIES OF SOILS AT THE NEVADA TEST SITE

V.Q. HALE, Univ. of California, Lab. of Nucl. Med. Rad. Biol., *Los Angeles, California* 90024 (AT(04-1)GEN-12)

The objectives of this project are to classify the soils of the Nevada Test Site and to correlate the chemical properties of specific soils with the chemical composition of their associated perennial plants. This is designed to broaden the understanding of the desert plant ecology and to provide background information for the study of radiation effects on the desert plant biome. Soil pits were dug with a back hoe at 75 locations which were selected for diversity of plant growth habit and/or species population. In each pit the soil profile was described according to the system used by USDA Soil Conservation Service and soil horizon samples were taken under a shrub clump and in bare area for laboratory analysis of physical and chemical properties. Perennial vegetation was sampled in the immediate vicinity of each pit for spectrographic analysis. Data will be centered on punch cards to facilitate analysis by computer.

Results: All of the soil profiles have been described and sampled and the spectrographic analysis of the plants has been completed. Soil samples from six of the pit sites (a total of 46 samples) have been completely analyzed for particle size distribution, water retention, soluble cations and anions, and exchangeable cations.

5.0154, FISSION PRODUCT CYCLES IN AN AGRICULTURAL SYSTEM - VALIDATION OF MODEL

H.A. HAWTHORNE, Univ. of California, Lab. of Nucl. Med. Rad. Biol., *Los Angeles, California* 90024 (AT(04-1)GEN-12)

A growth chamber test was made of the effects which different levels of nitrogen fertilizer had upon uptake, distribution within tomato plants, and the concentration of Sr90 in tomato leaves, stems and roots. Soil from the dairy farm being modeled was included with other calcareous soils to obtain a range in free clacium carbonate that decreased from 33% to 0%. Soil science theory, and experimental verification, indicate that uptake of Sr90 by plants is inversely proportional to the level of exchangeable calcium in soil. Calcareous soils, by definition, have high levels of calcium minerals bathed by soil solution. Sr90 competes with dissolved cations for exchange sites in soils, is adsorbed on insoluble calcium minerals, and is concurrently absorbed by plants. No theory exists that gives quantitative predictions for the outcome of the competing probabilities under which Sr90 moves from the soil. This study provides empiric definition of the relative uptake of Sr90 by a test plant under standard conditions, and may give insight into limiting processes controlling Sr90 release from soil, used in the model of the system. The minimum outcome of the experiment is a series of numerical determinations useful in

perturbating the model, evaluating the response, then injecting the farmers fertilizer rates into the model and comparing that outcome to strontium analyses on plants from the farm system.

Results: A manuscript was prepared for publication and summarized the effects of nitrogen applications. Additional stable element analyses are in progress on the plants for calcium, stable strontium and potassium. The concentrations of Sr90 in leaves are independent of the free calcium carbonate % and of nitrogen rates. Stems and roots had higher Sr90 concentrations with increases in nitrogen fertilizer.

5.0155, NUCLIDE METABOLISM

N.S. MACDONALD, Univ. of California, Lab. of Nucl. Med. Rad. Biol., *Los Angeles, California* 90024 (AT(04-1)GEN-12)

The objective embraces: study of the behavior of various atomic species normaly present in the human body (Ca, Na, K, Cl, Mg, Fe, etc.,), seeking correlations of abnormal behavior with disease states by using radioactive forms of these materials; study of the metabolism, tissue distribution and excretory patterns of new, radioactive agents being evaluated for clinical usage in nuclear medicine; and finally, investigation of the metabolism of various radionuclides which are either currently or potentially significant contaminants of the human environment such as Cs-137 and Sr-90).

This work is carried on by experiments with laboratory animals and by collaborative investigations with staff physicians at the Hospital of the UCLA Center for Health Sciences. Techniques include radiochemical analyses of body tissues and excreta and repetitive monitoring of radioactivity at various areas of the living animal using external detectors.

A Total Body Counter Facility is operated for detection and identification of extremely small quantities of radioactive materials in living human beings. It is used to measure the gamma radioactivity in children and adults drawn from the local population, to monitor the level of environmental contamination. It is also used in clinical research and diagnostic tests wherein materials labeled with infinitesimal amounts of radioactive tracers are administeted to patients in order to measure the absorption and retention of these materials in their bodies.

Results: Measurements of the oral absorption of iron, manganese and copper were made in patients with iron-storage disease, using traces of Fe-59, Mn-54 and Cu-67 and the Total Body Counter. No significant correlation has yet been found between the absorption and retention of manganese or copper and abnormal iron metabolism. The rates of metabolic synthesis of immune globulins IgG and IgM were shown to be 3 times normal in patients with rheumatoid arthritis, using radioactive iodine- 131 and iodine-125 as labels for these normal blood proteins.

5.0156, RADIATION CHEMISTRY OF NUCLEIC ACIDS AND RELATED COMPOUNDS

L.S. MYERS, Univ. of California, Lab. of Nucl. Med. Rad. Biol., *Los Angeles, California* 90024 (AT(04-1)GEN-12)

The purpose of this work is to determine the chemical mechanisms of the initial radiation induced reactions which are responsible for the biological effects of radiation, and to develop means of modifying these reactions. Results will provide a rational basis for developing methods of protecting against radiation effects and of using radiation effects in beneficial ways such as in cancer therapy. Reactions of nucleic acids and nucleic acid constituents a) following deposition of energy directly in the organic molecules, and b) with hydrogen atoms, hydroxyl free radicals, and hydrated electrons formed by deposition of energy in water are being investigated. Techniques used include those of conventional radiation chemistry and biochemistry, pulse radiolysis, and electron paramagnetic (or spin) resonance spectroscopy (EPR).

Results: Recent work includes: 1) study of the mechanisms by which substitution of 5-bromouracil for thymine in DNA sensitizes cells to radiation, 2) investigation of rates of formation, reactivity, and structure of free radicals formed by reaction of hydroxyl free radical with pyrimidine bases and with DNA, 3) determination by EPR of the structures of free radicals formed in irradiated single crystals of nucleic acid constituents, and 4) investigation of the radiolysis of thymine in frozen aqueous solutions.

5.0157, RADIATION STUDIES ON ISOLATED CHROMOSOMES

A. NORMAN, Univ. of California, School of Medicine, *Los Angeles, California* 90024 (AT(04-3),PROJ.0118)

The objective of these studies is to determine the chemical and physical mechanisms involved in the production and repair of radiation damage in human chromosomes. In particular the connection between chromosome aberrations, the rates of production and repair of DNA strand breaks and other DNA lesions, and the kinetics of unscheduled DNA synthesis will be investigated in human normal and leukemic leukocytes. A comparison of the rates of these various processes among leukocyte populations that differ greatly in content of DNA polymerase and other enzymes together with studies on the production of radiation damage in isolated chromosomes should help elucidate the role of specific enzymes in radiation damage and its repair. In addition it is hoped that these studies will lead to better methods for detecting radiation damage in human populations and to a deeper understanding of the structure of human chromosomes.

A study of the kinetics of unscheduled DNA synthesis in human lymphocytes has permitted the characterization of the rate limiting enzymatic step in terms of activation energy, Michaelis constant, temperature maximum, number of enzymes per cell, nucleotides incorporated per rad into DNA, and lesions per cell per rad.

SUPPORTED BY U.S. Atomic Energy Commission

5.0158, RADIATION DAMAGE AND ITS REPAIR IN HUMAN CHROMOSOMES

A. NORMAN, Univ. of California, School of Medicine, *Los Angeles, California* 90024 (AT(043))

The objective of these continuing studies is to determine the chemical and physical mechanisms involved in the production and repair of radiation damage in human chromosomes. The studies on the kinetics of unscheduled DNA synthesis will be extended to characterize the rate limiting step induced by ultraviolet light and X-rays in human lymphocytes and granulocytes. Studies on the kinetics of strand break repair will be extended to characterize the rate limiting step in both the G sub o and S phases in human lymphocytes. By the use of fluorochromes and a flow fluorimeter measurements will be made of the DNA content, the extent of DNA-histone binding, and other properties of the nuclear chromatin within intact lymphocytes. The effects of irradiation and of PHA activation on these cytochemical properties will be studied and correlated with the studies on DNA breakage and repair, and on other phenomena of importance in the radiation biology of human lymphocytes.

Results: Two sets of experiments have been concluded; one on the temperature dependence of unscheduled DNA synthesis, the other on the kinetics of unscheduled DNA synthesis at low X-ray doses. As a result it has been possible to obtain estimates for a number of parameters characterizing the rate limiting step of the fast process; the number of enzyme molecules per cell, the activation energy, the temperature of maximum rate, the half-life of the rate controlling step, the radiation induced lesions per rad cell, the nucleotides incorporated per lesion, and the Michaelis constant.

5.0159, RADIOECOLOGY OF DESERT VEGETATION AND SOILS

E.M. ROMNEY, Univ. of California, Lab. of Nucl. Med. Rad. Biol., *Los Angeles, California* 90024 (AT(04-1)GEN-12)

Research activities aim to a better understanding of (1) radioactive fallout damage to desert vegetation, (2) ecological relationships among plants and soils, and (3) the mineral nutri-

tional characteristics of desert shrubs and their response to the manipulation of environmental factors known to influence plant growth and development. Investigations are conducted in field and laboratory environments in order to bridge the gap between practical and theoretical problems arising from radioactive fallout contamination, and also to increase understanding of some functional and homeostatic factors involved in maintaining the integrity of vegetation in the desert ecosystem. Beta irradiation damage to vegetation from radioactive fallout has been identified and documented. We are continuing to study the recovery of vegetation and the persistence of radionuclides in fallout areas at the Nevada Test Site. Field plots have been established to investigate the response of desert vegetation to supplementary irrigation and fertilization. A marked response in vegetative growth and new seedling establishment has occurred in irrigated plots. A dimensional analysis of an association of desert shrubs in hardpan soil is underway.

Results: A survey of the mineral element composition of desert plants is in progress in conjunction with a survey of chemical and physical properties of pertinent soils in order to help evaluate the influence of edaphic factors on shrub distribution. Laboratory support work in progress includes studies of the effects of soil temperature and moisture on the phenology and growth of desert shrub species, the sensitivity of these shrubs to gamma irradiation, and their mineral nutritional characteristics and peculiarities.

5.0160, CONTINUOUS GAMMA IRRADIATION OF NATURAL POPULATIONS OF DESERT ANIMALS

F.B. TURNER, Univ. of California, Lab. of Nucl. Med. Rad. Biol., *Los Angeles, California* 90024 (AT(04-1)GEN-12)

This field study examines the effects of gamma radiation on animals, with emphasis on three aspects of the problem difficult to assess in the laboratory. First, we are considering the effects of long exposure to very low (sublethal) dose rates. Second, we are examining the performance and fate of natural populations of interacting animals. Third, we are considering radiation effects within the context of the natural environment, including natural stresses and influences as well as the experimentally imposed radiation. A fenced 20-acre area in southern Nevada is exposed to free-air dose rates of about 5 R/day from a centrally located source of 33,000 Ci of Cs137. The performances of selected animal populations within this area have been followed for six years. The animals occupying three adjoining 20-acre areas have also been followed, and serve as controls. Tissue doses to animals have been measured with implanted or attached lithium fluoride microdosimeters. Annual doses to small rodents and lizards are estimated at around 300- 750 rads, with most of the exposure occurring during the spring and summer.

Results: To date, the irradiated population of the common but short-lived uta (Uta stansburiana) has continued to function in an apparently normal manner. The less common, long-lived, leopard lizard (Crotaphytus wislizenii) has not reproduced in the irradiated area since 1966, although normal reproduction has been observed in the control plots. The failure is attributed to female sterility induced by cumulative gamma doses of less than 2000 rads. The difference in response of these two species is apparently owing to their differing life-spans.

5.0161, BEHAVIOR OF CERTAIN SYNTHETIC CHELATING AGENTS IN BIOLOGICAL AND SOIL SYSTEMS

A. WALLACE, Univ. of California, School of Agriculture, *Los Angeles, California* 90024 (AT(04-3)-34)

A study is in progress of the elucidation of principles involved in the effects of synthetic chelating agents on behavior in plants of heavy metals (including micronutrients) and of radionuclides of heavy metals. The behavior of most concern is the uptake from soil and distribution in plants of some radionuclides. Past studies have indicated that certain chelating agents correct micronutrient deficiencies in plants. Some increase the uptake only of the metal with which the agent is chelated, while others have a great influence on uptake and distribution in plants of other heavy metals and also of some radionuclides which may be in the soil by contamination. Very important findings are indicated for the radionuclides Y90, Am241, and we hope that an elucidation of the principles involved will help to predict what could happen to many other radionuclides. The additions of some iron chelates to soil in high levels induces deficiencies of other micronutrients such as manganese. Progress to date of studies of this behavior is indicating that only some agents have this effect and that it is related very much to levels applied. Other chelating agents even when applied with iron increase the uptake of the very elements that the other agents cause deficiencies for.

We are studying the principles of these reactions so that eventually it will be possible to predict behavior for any agent. As part of a total study of chelating agents in soil and in biological systems, the uptake and metabolism of the agents themselves continue to be studied. Some attention is also directed towards the physiological effects of the metals themselves in plant nutrition. Interactions among metal and chelates, among different metals, and factors regulating the uptake of all are being considered.

Results: Several studies have been made and reported in the literature.

5.0162, XYLEM EXUDATE COMPOSITION AND ITS RELATIONSHIP TO SOLUTE ACCUMULATION AND TRANSPORT

A. WALLACE, Univ. of California, School of Agriculture, *Los Angeles, California* 90024

Intensive study of the root pressure - exudation phenomenon in tobacco roots has identified some areas worthy of continued study among which is diurnal periodicity. Exudation from detopped tobacco follows a marked 24-hour cycle. This cycle is almost completely obliterated by phosphorus deficiency. Irradiation with Co 60 source to give levels of gamma rays which impair various kinds of nucleic acid synthesis (50,000 R) had no apparent effect on exudation but irradiation at levels which have injurious effects on enzyme systems (500,000 R) tended to destroy first the periodicity and then exudation itself. Nitrate nitrogen in the external solution tends to cause large increases in the exudation rate and tends to destroy or mask periodicity. This occurs, however, only at moderate and low temperatures 20 degrees C and lower. At higher temperatures (25 degrees C or higher) distinct periodicity is obtained even for very high nitrate levels. At least some ATPases are reported to have a high temperature optimum and the above observations can be organized into a working hypothesis that exudation periodicity is regulated by an ATPase possibly at the tonoplast as indicated by previous studies here. Salt release from vacuoles has been shown to provide the necessary water potential for the exudation to occur. Various consequences of the working hypothesis are to be tested and include effects of ATP on exudation, of ATPase inhibitors on exudation, of phosphorus level - irradiation interactions on exudation, of phosphorus level - nitrate level interactions on root metabolism. An attempt will also be made to study ATPases. Bicarbonate and CO2 have the opposite effect that nitrate does and the ramifications of this are also being explored.

5.0164, ESR STUDIES OF FREE RADICALS IN RELATION TO BIOLOGICAL EFFECTS OF RADIATION

W. WOLF, Univ. of Southern California, School of Pharmacy, *Los Angeles, California* 90033 (AT(04-3)-113,PA)

5. RADIATION

The overall purpose of the present project is to study the ESR characteristics of thiyl and related free radicals, in order to achieve a better understanding of the role of mercapto containing compounds, both in radiation damage and radiation protection processes.

A system has been developed for the study of thiyl and related free radicals in solution, both in a continuous flow and in a stopped-flow mode. For the latter, solenoid valves with closing time of less than 10 milliseconds have been built, and a number of other improvements introduced to facilitate dynamic studies of short lived free radicals.

The oxidation of thiols with ceric ion, in solution, leads to a number of free radical signals, ascribable to at least 6 different species. Some of them, like the RS, have been conclusively identified, while others have been only tentatively assigned (RSO2 and RO). Three other signals defy, at this time, even tentative assignment.

At this time, the ceric ion remains the most versatile oxidizing system; attempts to use other homogeneous or heterogeneous phase one electron transfer agents have been unsuccessful. Attempts are presently underway to build a UV laser, which would be capable of generating a high concentration of free radials directly in the cavity. If this gas laser works as expected, we would be able to produce selected photochemical reactions by varying the wavelength used.

Of particular interest is the hydrogen transfer reaction observed in mercaptoethanol, which might prove to be an interesting model system for the study of radical site migrations. Perhaps the most exciting result this present year is the splitting of the ESR signal arising from the cysteinyl residue in glutathione, suggesting the possiblity of utilizing the thiyl free radical as an internal spin label.

5.0165, PROTRACTED RADIATION EFFECTS
D.C. JONES, Stanford Research Institute, *Menlo Park, California* 94025 (DAHC20-70-C-0219)

Technical Objective: To determine the effects of protracted gamma irradiation on appropriate species of large animals in terms of radiation injury, recovery, and physiological alterations, for the purpose of improving quantitative models of radiation injury and recovery extrapolatable to man.

SUPPORTED BY U.S. Dept. of Defense - Army

5.0166, WEAPONRY--RADIATION DAMAGE BY NUCLEAR BLASTS
C.E. MENNEKEN, U.S. Navy, Postgraduate School, *Monterey, California* 93941

Technical Objective: This research concerns itself mainly with the problems and processes associated with nuclear explosions and the effect of radiation on materials. This is in direct support of studies of shielding against radiation damage to personnel and materials, particularly to semiconductor elements. Included is a study of the photochemical degradation of HMX and related explosives, as well as examination of catalysts such as palladium as required in the synthesis of new fuels and propellants.

SUPPORTED BY U.S. Dept. of Defense - Navy

5.0167, GENETICS OF RADIATION AND RADIOMIMETIC AGENTS
J. GREENBERG, Palo Alto Medical Res. Found., *Palo Alto, California*

The objective of this investigation is to discover how cells become resistant to high energy radiations and to certain chemicals resembling radiation in their biological effects. It has already been established in this and other laboratories that there are several different mechanisms responsible for resistance to radiation in bacteria. These mechanisms are under the control of at least four, and probably more different genes. It has also been established that the most sensitive cellular target of both radiation and radiomimetic chemicals is DNA.

Continuing along lines previously established, we shall map as vigorously as possible all genes responsible for radiation resistance. We shall try to establish the function of each gene, and how the different genes interact. We shall at the same time continue to elucidate how radiomimetic chemicals injure DNA and how such injury is prevented, circumvented or repaired in resistant organisms.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0168, REAL-TIME SPACE AND NUCLEAR EFFECTS ON SOLAR CELLS
H.E. POLLARD, Philco Ford Corporation, *Palo Alto, California* 94303 (F33615-70-C-1207)

Technical Objective: Determine the real-time effects of space and nuclear environments on conventional and newly developed hardened solar cells.

SUPPORTED BY U.S. Dept. of Defense - Air Force

5.0169, MODIFICATION OF RADIATION RESPONSE IN VITRO
G.M. HAHN, Stanford University, School of Medicine, *Palo Alto, California* 94305

In mammalian in vitro the monoalkylating agent, Methyl Methane Sulfonate (MMS) induces sublethal damage in DNA which is capable of repair by unscheduled DNA synthesis. This repair can be inhibited by concomitant treatment with hydroxyurea (HU).

Unexpectedly high survival rates have been observed when dense cultures of mammalian cells (hamster ovary) are heavily irradiated in plateau phase. The survival ten to one thousand times greater than could be predicted from conventional dose log survival curves are observed. It appears that the condition of crowding contributed to more efficient repair of sublethal damage similar to the phenomenon of 'neighbor rescue' which has been observed in bacteria. The experiments are in progress to delineate whether or not the above observation is merely another manifestation of 'deoxygen effect'. It is possible that the oxygen consumption in these dense cultures is sufficiently high to deoxygenate the medium, creating a hypoxic environment at the time of the irradiation.

Using diffusion rates of serum from culture medium into cells as a limiting factor for cell division, a model has been formulated for predicting the growth patterns of specific cell lines. Experiments are in progress in order to verify the model by studying the rate of exhaustion of serum and its relationship to the growth patterns of two cell lines, Chinese hamster ovary cells and primary cultures of embryonic rat fibroblasts.

5.0170, PHOTO- AND RADIOCHEMICAL REACTIONS OF NUCLEIC ACIDS
K.C. SMITH, Stanford University, School of Medicine, *Palo Alto, California* 94305

We wish to continue and extend our studies on the effects of ultraviolet light, of photosensitizing dyes plus visible light, and X-rays upon the nucleic acids in vivo and in vitro. The objectives of this research are to elucidate the nature of the chemical changes produced in the nucleic acids by these radiations (with emphasis on UV); the biochemical consequences of these lesions (e.g., effects on macromolecular synthesis, etc.), and the biochemical mechanisms and genetic control of the repair of radiation damage in bacteria (with emphasis upon the relationship between genetic recombination and the repair of radiation damage).

The following specific problems will be investigated: (1) the radiation induced cross-linking of DNA and protein; its chemical nature, its biological consequences and its possible repair. (2) the effects of radiation on the kinetics of macromolecular synthesis and growth of bacteria. (3) the biochemical mechanisms and genetic control of the repair of radiation damage in bacteria (with emphasis upon the relationship between genetic recombination and the repair of radiation damage).

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0171, MOLECULAR BASIS OF RADIATION LETHALITY

K.C. SMITH, Stanford University, School of Medicine, *Palo Alto, California* 94305

Using the polymerase deficient mutant (polA1) that we have shown to be deficient in the fast repair (few minutes in buffer) of the majority of the X-ray-induced chain-breaks produced in the DNA of E. coli, we hope to measure the 'true' number of DNA single- and double-chain breaks produced by a given dose of X-irradiation under aerobic and anoxic conditions. We also plan experiments designed to elucidate the molecular bases of pol repair (fast repair) and rec repair (slow repair) of X-ray damage and for ways in which these repair systems can be inhibited.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0172, SEQUENTIAL STUDY OF ULTRASTRUCTURAL CHANGES IN EXPERIMENTAL RADIATION HEART DISEASE

L. FAJARDO, U.S. Veterans Administration, Hospital, *Palo Alto, California* 94304

It was reported that Radiation-Induced Heart Disease, as seen in humans, could be reproduced in New Zealand white rabbits.

The time-lapse study has revealed 3 SEQUENTIAL STAGES in the evolution of the disease. ACUTE STAGE (6 to 48 hours): acute inflammation of all layers of heart, which subsides. LATENT STAGE (2 to 70 days): no significant changes by light microscopy. LATE STAGE (70 days on): progressive fibrosis of myo and pericardium. The discovery of an ACUTE STAGE during the first two days supports the existence of an Acute Cardiovascular Radiation Syndrome. It may have special application in the management of nuclear accidents. The LATE STAGE is characterized by pericardial and myocardial fibrosis. The pericardial damage is associated with effusion, and 50% of animals living beyond 100 days develop congestive heart failure.

The electron microscopy of the LATENT STAGE has shown severe lesions of blood capillaries resulting in rupture and thromboses. Myo fibers show only minimal changes. These findings support our hypothesis that myocardial radiation disease is mediated through capillary injury.

Comparative radio-autography revealed at 39 days (LATENT STAGE) an increase in the incorporation of H-thymidine, exclusively by endothelial and interstitial cells.

5.0173, THE EFFECT OF LASER ENERGY ON CELLS IN TISSUE CULTURES

D.E. ROUNDS, Pasadena Found. for Med. Res., *Pasadena, California* 91101 (DA)

Technical Objective: To determine if subthreshold levels of laser energy in the green to infrared portion of the spectrum can produce cell (chromosomal, genetic) changes which can persist through several cell generations and to suggest a mechanism of action for producing such changes. These results will indicate whether combat soldiers and other military personnel working with lasers should consider the possibility of basic changes in the cells of their tissues exposed to this energy source.

SUPPORTED BY U.S. Dept. of Defense - Army

5.0174, DIFFERENTIAL RADIOSENSITIVITY IN GERM CELLS OF DROSOPHILA

D.R. PARKER, Univ. of California, School of Letters, *Riverside, California* 95606 (AT(04-3)-34/PA)

The objective is to characterize chromosomal rearrangements induced in primary oocytes and to determine the meiotic properties of the resultant interchange configurations, including effects on metaphase orientation, measurements of preferential segragation of heteromorphicc dyads, and effects on non-homologous pairings and on nondisjunction. The procedures involve the recovery and analysis of half-translocations, usually derived by meiotic interchange involving compound chromosomes (or in some cases supernumerary chromosomes), where the effects of the resultant aneuploidy do not preclude recovery and analysis. These are obtained by X-irradiating mature or immature oocytes of Drosophila melanogaster.

Results: Interchange induced in immature oocytes between chromosomes not involved in chiasmaconjoined bivalents results in the formation of 'quasi-bivalents' that follow the same rules of orientation as do true bivalents. Induced nondisjunction occurs in the ways predicted by this model. Interchange induced in mature oocytes seemingly does not alter already established patterns of segregation.

5.0175, EFFECTS OF FALLOUT ON AGRICULTURAL ECOSYSTEMS

V.M. STERN, Univ. of California, Graduate School, *Riverside, California* 92502 (DAHC20-69-C-0294)

Technical Objective: To conduct a detailed study of the effects of fallout radiation on a highly concentrated agricultural ecosystem, including an analysis of the effects on various food and forager crops and their related insect pests that may be created by imbalances in crop/pest survival and when pesticide use is prevented or restricted.

SUPPORTED BY U.S. Dept. of Defense - Army

5.0176, PULSE RADIOLYSIS STUDIES

L.P. THEARD, General Dynamics Corporation, *San Diego, California* 92112 (AT(04-3)-167,PA36)

The major goal of this research is the elucidation of indirect mechanisms by which ionizing radiation induces chemical transformations in nucleic acids, its components and related compounds, and in aminothiols and radiation sensitizing agents. The plan of the research is to study first the purines, pyrimidines, nucleosides, nucleotides, and nucleic acid in an effort to understand the radiation chemistry of these compounds sufficiently to render them useful as biomolecular models in radiation protection and sensitization studies. In other words, if the radiation chemistry of these systems is understood, effects induced by the presence of aminothiols and other agents may be interpretable in terms of mechanism. The use of the pulse radiolysis technique in this approach is particularly effective since transient free-radical processes are observable directly leading to rate constants and mechanistic details.

Results obtained thus far include the detection of free radical products of the reactions of hydroxyl radicals, hydrated electrons, and hydrogen atoms with nucleic acid and various of its constituents. In many cases the molecular site of free radical addition has been determined. Also determined are absolute reaction rate constants for many of the reactions. From the effects of pH, rate constants for protonation of anions and hydroxylion-induced dissociation of hydroxyl- radical adducts have been determined.

Rate constants for reaction of hydroxyl radicals and hydrated electrons with cysteine have been determined along with absorption spectra of some free-radical products of this protective agent. Other results on pyrimidine bases and nucleic acid containing substituted bromine have revealed details of reaction mechanisms that may pertain to radiation sensitization.

Work in progress and planned for the future includes studies of mixtures of aminothiols with nucleic acid and its constituents, and a study of hydroxyl radical reactivity with a series of aminothiols which vary systematically in molecular structure.

5.0177, X-RAY INDUCED CHANGES IN DROSOPHILA GERM CELLS

R.R. RINEHART, San Diego State University, School of Liberal Arts, *San Diego, California* 92115 (AT(04-3)-590)

Stage 7 and 14 primary oocytes of Drosophila melanogaster were irradiated and egg survival, X- and Y-chromatid in-

terchange, sex- chromosome loss, or sex-linked recessive lethality were used as measures of damage. Modifications of radiation damage included either extended anoxic treatments or exposure fractionations to demonstrate possible repair. The results to date indicate that Stage 7 oocytes repair all of these kinds of damage while Stage 14 oocytes do not.

The radioresponse of oogenic cells earlier than the Stage 7 primary oocyte is being investigated. The approach is to irradiate larvae and pupae with the different oogenic stages as their most mature cell type, allow the cells to mature to eggs, and sample only the first cells from each treated female. Fertility, viability, and number and cytological condition of the ovarioles will aid in determining the cell sample recovered. A comparison of interchange kind and frequency associated with either reversed metacentric or reversed acrocentric attached-X chromosomes may help elucidate possible meiotic configurations, as well as cell types sampled.

SUPPORTED BY U.S. Atomic Energy Commission

5.0178, BASIC STUDIES OF THE IMMUNE RESPONSE AND THE EFFECT OF RADIATION ON THIS RESPONSE

F.J. DIXON, Scripps Clinic Res. Fdn., *San Diego, California* 92037 (AT(04-3)-410)

The Effect of X-Radiation of Macrophage and Lymphocyte functions in the Immune Response - The ability of macrophages to catabolize antigens and to present them in an immunogenic form will be observed after exposure to varying doses of radiation. These two functions are thought to be quite distinct and may be affected differently by radiation. The effects of radiation on Ig bearing lymphocytes and lymphocytes without Ig will be observed in order to determine relative radiosensitivity of these two cell types. Also the radiosensitivity of specific antigen binding lymphocytes will be determined before and after exposure to antigen.

Etiologic Factors in Human Glomerulonephritis - The several isolated non-collagenous glomerular basement membrane protein antigens will be tested for reactivity against anti-GBM antibodies from 15 patients. If one or more of these antigens are particularly involved in this auto-immune response a possible means of their release 'in vivo' will be looked for. The search for virus possibly associated with the etiology of immune complex type glomerulonephritis will be continued with special emphasis on the search for E-B virus antigens in the glomeruli or antibodies in the serum.

Macrophages have been observed to catabolize the antigenic materials they phagocytose and to fix on their surface, apparently in a strongly immunogenic form, non-catabolized antigen. Approximately 50% of mouse spleen lymphocytes have surface Ig. A few % of lymphocytes from previously stimulated mice have specific receptors for the antigen employed. Six non-collagenous protein antigens have been isolated from human GBM.

5.0179, ESTIMATING THE GENETIC HAZARDS OF ENVIRONMENTAL AGENTS

J.A. HEDDLE, Univ. of California, Laboratory of Radiobiology, *San Francisco, California* 94122 (AT(11-1)-GEN)

An attempt is being made to develop a rapid and sensitive test for chromosomal breakage. The criterion is to be the micronuclei produced when chromosomal fragments are not included in the daughter nuclei at cell division. To minimize the extrapolation necessary to estimate risk, mice will be tested in vivo. Furthermore, it may be possible to use meiotic cells which are the important cells insofar as the human population is concerned.

Results: Experiments on broad bean root tips indicate an efficiency of scoring chromosomal damage that is between 10 and 100 times that achieved with metaphase scoring. A significant increase over control in micronuclei after 2.5 R was demonstrated with an hour's scoring. Micronuclei are detectable in mouse bone marrow after irradiation. The relative efficiency of scoring is currently being estimated. No effect of benzpyrene was detected using micronuclei production in bean roots and conventional metaphase scoring of human leucocytes and Chinese hamster cell cultures. This suggests that the well-known correlation between chromosomal breakage and carcinogenesis does not mean that aberrations cause cancer.

5.0180, RADIATION EFFECTS ON CAPILLARIES AND STROMAL ELEMENTS

T.L. PHILLIPS, Univ. of California, Laboratory of Radiobiology, *San Francisco, California* 94122 (AT(11-1)-GEN)

Radiation effects on capillary endothelial cells and stromal cells are being studied in mouse tissue directly by electron microscopy and indirectly by end points such as the LD sub 50/160 days for lung or kidney irradiations. The objective is to discern relationships between radiation dose, exposure pattern, and degree of injury which may be useful in development of procedures for modification of tissue tolerance.

Results: Capillary endothelium is the principal site of injury in lung, muscle and heart after doses of 2000 rads. Kidney damage reflects injury to cells of the convoluted tubules as well as capillaries. The single dose LD sub 50/160 is 1300 rads for lung and 1500 rads for kidney. This parameter for lung irradiation increases with the number of dose fractions (slope of 0.39). Time between fractions is of little importance. The single dose pulmonary LD sub 50/160 is not altered by actinomycin-D or hydroxyurea, but the multiple dose LD sub 50/160 is reduced by repeated treatment with actinomycin-D.

SUPPORTED BY U.S. Atomic Energy Commission

5.0181, ULTRA-HIGH DOSE RATE RADIOBIOLOGY

T.L. PHILLIPS, Univ. of California, Laboratory of Radiobiology, *San Francisco, California* 94122 (AT(11-1)-GEN)

The object of this project is to determine the effect of radiations delivered at dose rates above 10 to the 10th power rads per second on mammalian cells in vivo and in vitro. Alterations in biological effectiveness and in the oxygen effect are possible with these dose rates. A decrease in the oxygen effect would be of use in clinical radiation therapy. Dose response relationsips for mouse bone marrow cells and hamster B14FAF cells are determined at various oxygen concentrations with dose rates of 100 rads per minute and 10 to 10th power rads per minute on an 11 MeV electron linear accelerator. Cell response in vivo has been evaluated by exposure of the skin of mice over the thorax and over the feet to electrons at both dose rates. The lungs of mice have also been irradiated and the response evaluated by the lung LD sub 50/160 technique.

Results: Experiments indicate that 2700 rads delivered at conventional dose rates on the accelerator is equivalent to 4200 rads in a single pulse. Dose response curves for skin reaction were obtained with conventional and ultra high dose rates. There was a decrease in response with the latter at doses above 1500 rads. Similar comparison failed to disclose a difference in the pulmonary LD sub 50/160 for conventional and ultra high dose rates.

5.0182, CHROMOSOME STRUCTURE AS REVEALED BY RADIATION STUDIES

S. WOLFF, Univ. of California, Laboratory of Radiobiology, *San Francisco, California* 94122 (AT(11-1)-GEN)

Although we know that chromosomes consist of proteins and nucleic acids, we still do not know how these components are chemically or physically arranged to form the genetic material of higher organisms. Without this knowledge we cannot understand how radiation interacts with chromosomes to induce mutations, genetic damage, and cell killing. Biophysical and biochemical experiments on the types of chromosome aberrations induced by radiation at different times throughout the cell cycle and on the chemical nature of the repair processes occurring when broken chromosomes reunite can be used to elucidate chromosome structure. To ascertain the chemical species required for linear continuity, the experimental approach is to induce broken chromosomes in cells of higher plants (Vicia, Tradescantia) and animals (Poteroo, hamster, man) and then to see which specific metabolic inhibitors prevent the repair or rejoining of the broken pieces. Other aspects of chromosome structure, such as the number and arrangement of strands within chromatids, are studied by disrupting the arrangement with chemical treatments and then inducing chromosome aberrations with radiation. From the

types of aberrations formed under these circumstances, it is possible to deduce the number of strands involved in the chromosome.

Results: The rejoining of chromosome breaks in human as well as in plant cells requires protein synthesis and not DNA synthesis. Furthermore, chromosome aberration induction is independent of DNA dark repair mechanisms in both plants and animals. The studies on the types of aberrations induced at various times in the cell cycle have led to the conclusion that each chromatid must be at least a two-stranded structure.

5.0183, EFFECTS OF BETA AND GAMMA RADIATION ON DESERT VEGETATION

W.A. RHOADS, E G & G Incorporated, *Santa Barbara, California*
(AT(29-1))

The purpose of this research is to elicit the effects on desert plants attributable to beta and gamma radiation from the particles distributed following nuclear cratering detonations. The fallout pattern is determined, and the beta and gamma doses to the close-in environment are measured at numerous locations. Over the short and long term, effects of the irradiation on naturally occurring desert plants are determined. As controls, one or more non-irradiated areas with histories of gross physical shock will be studied.

The evaluation of the effects of the close-in fallout from the Schooner event was continued. The highest beta dose was 10,500 R and the highest gamma dose 950 R. Artemisia (sage brush) was killed by ionizing radiation except for selected shrubs covered by polyethylene sheets prior to fallout arrival. In the center of the fallout pattern all exposed Artemisia were killed and all plastic covered shrubs survived. For covered shrubs the beta dose was reduced 49 per cent and the gamma dose 16 per cent, sufficient to reduce the total dose below the lethal dose for Artemisia.

5.0184, AGING OF BIOLOGICAL SYSTEMS IN SPACE MISSIONS

H. SOBEL, U.S. Veterans Administration, Hospital, *Sepulveda, California* 91343

Hairless mice were exposed to U.V. light from a Burdick lamp daily for from 10-20 min. as tolerance increased. One-half of the mice were permitted a recovery period of 6 months. After removal of a uniform 'button' from the back of the skin which consisted of the injured area which rendered the greatest amount of U.V., the skins of both groups were analyzed for salt soluble, acid soluble, guanidine soluble and residue collagen, hyaluronic acid, chondroitin sulfate, elastin, fluorescence/collagen, and aldehyde/collagen. There were no consistent differences from the controls except that fluorescence/collagen and aldehyde/collagen seemed to increase in the exposed group. The buttons did not reveal significant changes either in the connective tissue components although keratin was considerably increased.

Pregnant mice at days 3,6,9,12,16, and 18 during gestation were exposed for 72 hours to 27% oxygen at atm (rel). All pregnant mice exhibited an extremely high mortality rate. Animals in the last stages of pregnancy delivered young prior to death which could not be maintained by foster mothers.

Since exposure to high oxygen tension results in the increased fluorescence of collagen and since collagen fluorescence increases with age, acid soluble collagen was exposed to high oxygen tension and the fluorescent product was studied. The activation/emission spectrum of the pronase-digested material suggested certain similarities to oxidation products to tyrosine. This is in accordance with the findings of LaBella. Accordingly several amino acids were exposed to the same conditions and it was observed that certain similarities existed between activation/emission spectrum of oxygen exposed collagen and tyrosine. At the time of my separation from the Veterans Administration we were working with acid soluble collagen which had been labeled with C14 tyrosine.

5.0185, CELLULAR AND MOLECULAR STUDIES OF RADIATION DAMAGE AND REPAIR IN CULTURED MAMMALIAN CELLS

L.D. SKARSGARD, Mcmaster University, *Hamilton, Ontario, Canada*

It has been shown that the organic free radical triacetoneamine N- oxyl (TAN) preferentially sensitizes anoxic Chinese hamster cells to X- ray damage. A dose modifying factor (DMF) of 1.5 was obtained for a concentration of 10-2 Molar TAN compared with a DMF for oxygen of 2.8. The failure of other investigators to obtain sensitization with TAN in mice prompted a series of electron spin resonance studies on the fate of the free radical inside the cell. These measurements showed that the free radical is reduced inside the cell according to zero order kinetics and suggested that no sensitization could be expected unless the dose is delivered within 15 minutes after administration of the drug. We have also shown that synergism exists between the separate effects of the drug and radiation.

Sedimentation studies on mammalian DNA have shown that ionizing radiation damage and repair can be correlated with the molecular integrity of the DNA.

Survival curves have been measured at different stages of the cell cycle using densely ionizing radiations (LET range 20-5600 MeV-cm2/gm. G2 cells, which are sensitive at low LET, become resistant at high LET. This may indicate that some event such as duplication or condensation of the genome renders the cell more resistant to single-hit killing by high LET particles, though it does not appear to do so for lower LET radiations where damage must be accumulated.

5.0200, EFFECTS OF WHOLE BODY GAMMA-RADIATION ON THE RESPIRATORY CHAIN OF MITOCHONDRIA AND THE ANAEROBIC GLYCOLYSIS OF NEW BORN CNS
E. EGANA, Univ. De Chile, *Santiago, Chile*

Our Institute has published elsewhere results on the respiration 'in vitro' of all CNS levels; on aerobic and anaerobic glycolysis; ATP content and synthesis and Cr-P synthesis; synthesis and content of ACh in diverse CNS levels; choline-transferase, 5-HT synthesis and content; and, H2O2 and catalase effects in CNS levels respiration. In these studies Beta-internal radiation has been used. Also on mitochondria respiration and conversion of (1-C14) -glucose into free amino acids of encephalon of adult CNS whole body gamma-irradiated.

The growing CNS is more radiosensitive than the adult one. In mitochondria of foetal, new born and impuber whole body gamma-irradiated rat (dose 5,50 and 500 R), the respiratory process will be studied with a special emphasis on the action of substrates (succinate and glutamate as donors of e), of energy sources (ATP and ADP) and carriers of electrons (NAD,FAD, Co6, Co10 and cytochromes); the RCR will be analyzed as also the ADP/O ratio, the oxidative phosphorylation and the anaerobic glycolysis. The study will commence with the new born, to be followed by the analysis of other stages of growing CNS.

5.0202, RADIATION EFFECTS IN CHEMISTRY AND BIOCHEMISTRY
B.M. TOLBERT, Univ. of Colorado, School of Arts, *Boulder, Colorado* 80304 (AT(11-1))

We have proposed that radiation inactivation of solid enzymes proceeds by several chemical mechanisms. These include relatively non- specific alterations of amino acid residues constituting the active site, direct conformational structural changes that may or may not be related to a chemical change, and a few specific chemical changes, for which loss or alteration of -SS- or -SH groups is a good example. In this research we are separating irradiated egg white lysozyme into fractions by salt precipitation followed by column chromatography on Bio-Rex 70 or Bio Gel. These fractions are then analyzed by a variety of physical and chemical techniques. In the next year we propose to continue our work on the fractionation of lysozyme and the comprehensive study of the individual fractions. Analytical methods include UV spectroscopy, denaturation sensitivity, ammonia, -SS-, aldehyde

and -SH group assays, assays for specific amino acid residues, enzymic activity and molecular weight by ultracentrifuge or sodium dodecyl sulfate polyacrylamide gel electrophoresis. In our studies we have been able to relate some of the protein changes to specific chemical changes and to obtain data to confirm some of the mechanisms proposed above.

5.0203, EFFECTS OF RADIATION FROM NUCLEAR EXPLOSIONS ON NATURAL VEGETATION
M.L. CANNON, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

States to which project pertains: Nevada.

Since 1962, periodic examinations have been made at regular distances from 24 nuclear shot points, of both contained and vented explosions and also from 40 dynamite shots, all of which have been detonated at different depths and with different charges, in order to learn what effects on vegetation should reasonably be expected from various types of nuclear detonations. Little effect on the growth of plants can be observed in the vicinity of contained shots unless there is a gradual escape of gas along fractures. Vented explosions cause widespread radiation damage to the flora over a period of at least 9 years. Deciduous shrubs and trees commonly enter a resting period from which they gradually emerge - time dependent on distance from shot. Conifers gradually die at ever increasing distances with time. These conclusions have been documented by photographs, autoradiographs, analyses, and wood sections.

5.0204, AMCHITKA GEOLOGIC INVESTIGATIONS
L.M. GARD, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

States to which project pertains: Alaska.

The overall objective of this project is to determine the suitability of Amchitka and Rat Islands, Alaska as a supplemental test site for underground nuclear testing.

Specifically this project: 1. Is determining the stratigraphy and structure of the islands. 2. Is determining the tectonic framework of the island relative to island arc structure. 3. Has determined the physical, hydrologic, and geothermal properties of the rocks at depths to 7,000 feet to provide safe sites relative to construction, containment, contamination, and ground motion for underground tests. 4. Has evaluated the effects of an underground nuclear explosion of about 1 megaton on the geologic and hydrologic environment in order to predict effects of future explosions. 5. Has synthesized available data to develop a plausible tectonic model for the western Aleutian arc.

Objectives for the future are: 1. To continue to refine geologic mapping. 2. To continue studies of the tectonic framework of the Aleutian arc to aid in the investigations of aftershocks and seismic phenomena. 3. To evaluate geologic and hydrologic effects of future underground nuclear explosions.

5.0205, ABILITY OF ISOLATED KUPFFER CELLS TO POPULATE EXPERIMENTAL GRANULOMAS AND IRRADIATED BONE MARROW
D.M. MILLS, U.S. Veterans Administration, Hospital, *Denver, Colorado* 80210

Hypothesis: Since isolated Kupffer cells resemble blood monocytes morphologically, they may be able to function in experimental situations which require mononuclear macrophages. A. Ability of Kupffer cells to populate granulomas: Foreign body carrageenin and tuberculin granulomas were produced in inbred rats. Donor animals received carbon particles I.V. to label Kupffer cells. The livers of these animals were disaggregated and injected I.V. into animals, with developing granulomas on day 2,4 and 5. On day eight 1 to 3% of the granuloma macrophages contained carbon, verified by electron microscopy. Other animals were then given 700r of total body irradiation 3 days before granuloma induction. Kupffer cells were given as before. The granulomas, although smaller, contained no carbon labelled macrophages. The carbon- containing macrophages in the first granulomas were of bone marrow origin, a result of reutilized carbon label. Carbon I.V. gave the same results. B. Ability of Kupffer cells to protect from radiation death: The median survival after 950r total body radiation is 6 days; Kupffer cells I.V. lengthened this to 9 days. Irradiation with the exteriorized liver shielded gave a median 6 days survival; with sham operation the survival was 6 days. C. Ability of Kupffer cells to repopulate bone marrow after radiation: Adult rats received 4000r to the left tibia. After 100 days the marrow space was reamed out and a suspension of homologous cells replaced. Isolated Kupffer cells, pieces of skeletal muscle, pieces of liver did not restore the marrow. A suspension of isologous bone marrow did lead to normal marrow.

Project continues.

SUPPORTED BY U.S. Veterans Administration

5.0206, BLOOD FORMATION IN THE EMBRYO (NEWBORN) OPOSSUM
M.H. BLOCK, Univ. of Colorado, School of Medicine, *Denver, Colorado* 80220

This animal, born at a 12-day gestation, has reached a stage of development corresponding to an 11-day mouse or 8-week human embryo. The thymus is an epithelial sheet, lymph nodes have not formed, hematopoiesis has begun in the liver and the animal is immunologically imcompetent. Utilizing these characteristics the following are now under investigation: 1) The effect of radiation on the spleen with special reference to feed-in from the stem cell compartment, and upon onset of lymphopoiesis. 2) The inflammatory response prior to formation of lymphocytes, when lymphocytes are formed only in the thymus and when lymphocytes are derived from extrathymic sources. 3) Maturation times of red cells, granulocyte precursors and of megakaryocytes. 4) Effect of erythropoietin on 'embryonic' hematopoiesis.

5.0207, THE CYTOGENETICS OF URANIUM MINERS EXPOSED TO RADON 222
W.F. BRANDOM, Univ. of Denver, School of Arts, *Denver, Colorado* 80210

Uranium miners represent a sizable population of workers occupationally exposed to radiation hazards. The potential and real hazards have been documented by mine radiation dosimetry, lung inhalation studies, epidemiology, bioassay and sputum cell cytology studies. The studies provide data on the amount of Radon 222 in the mines, estimated cumulative radiation exposure to miners, the increased incidence of lung cancer, increased concentration of 210 Pb and Po 210 in the blood, and the relationship between sputum cell cytology and lung cancer. In view of these studies and the recognized association between radiation and chromosome aberrations, it is surprising that no comprehensive cytogenetic study has been done on these men.

The objective of the proposed study is to employ chromosome aberrations as a biological indicator of radiation effects in uranium miners. Peripheral blood leukocytes will be cultured by established methods and chromosome preparations analyzed for aneuploidy, chromatid gaps and breaks, dicentrics, tricentrics, rings, fragments, deletions, translocations and deviations in monocentrics from the Denver system of classification. Appropriate controls will be included in blind-study evaluations. The chromosome findings will be compared with sputum cell cytology and estimated cumulative radiation exposure categories of miners. The chromosome findings should be useful to the clinician for prognostic purposes and for the ascertainment of somatic cell changes in lymphocytes caused by Radon 222 inhalation.

5.0208, CELLULAR RESPONSES TO IRRADIATION
W.C. DEWEY, Colorado State University, School of Veterinary Medicine, *Fort Collins, Colorado* 80521

Sublethal and potentially lethal repair of X-ray damage, as measured by cell lethality and chromosomal aberrations in

synchronized Chinese Hamster cells, appear to be closely related. Further studies are planned to confirm and extend these relationships. Also, agents which sensitize the cells irradiated in various phases of the cell cycle are being studied in terms of effects on repair.

The immediate effects of X-rays measured by delay in progression of cells through the cycle is being investigated in terms of variations in sensitivity during the cycle and the particular periods in the cycle during which the cells are blocked. This delay phenomenon will be studied in relation to any disruption in normal ultrastructural changes which are being determined during the cell cycle and to the synthesis of particular types of RNA and protein.

5.0209, REPAIR OF RADIATION DAMAGE TO CELLULAR DNA

J.T. LETT, Colorado State University, School of Veterinary Medicine, *Fort Collins, Colorado* 80521

A definitive goal of the radiation biologist in the last three decades has been the detection of radiation damage in cellular macromolecules at doses in the biological range. During the course of the current investigation of the ability of cells to repair X-ray induced strand breaks in their DNA at different stages of the cell cycle a sucrose gradient sedimentation technique has been developed which will permit analysis of the damage induced in mammalian DNA at biological doses. With this method it is proposed to investigate: 1)The relationship between DNA strand breaks and surviving fraction at different stages of the cell cycle. 2) The capacity of different chromosome groups (by size) to rejoin DNA strand breaks. 3) The final expression of chromosomal damage at the level of DNA as chromosome aberrations. 4) The multicomponent DNA structure of the chromosome.

This will represent a logical extension of the present phase of the study with Chinese Hamster Ovary Cells.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0210, EFFECTS OF IRRADIATION ON THE IMMATURE MOUSE

D.J. NASH, Colorado State University, School of Natural Sciences, *Fort Collins, Colorado* 80521

The objectives of the proposed work are to assess the importance of age as a factor governing sensitivity to ionizing radiations. The project is concerned primarily with studying those effects aris..., from radiation administered during the period between birth and sexual maturity. The house mouse will serve as the experimental organism, and special use will be made of different inbred strains and selected marker genes in order to gain understanding of the interaction of genotype with age in conditioning the response to radiation. Both acute and long-term effects of irradiation are being studied. Determination of the LD50/30 values are being made for each of the ages. Recovery rate at each of several ages is being measured through the use of the 'split-dose' technique. Long-term effects of acute irradiation will be studied in the survivors of the LD50/30 studies. Effort is being made to ascertain the pathological changes and causes of death in the long-term survivors of mice that have been irradiated at 0, 2, 4, or 6 weeks of age. Special emphasis is being diRected in studying the changes in the hematopoietic system associated with natural and radiation-induced aging.

5.0211, RADIOECOLOGY OF SOME NATURAL ORGANISMS AND SYSTEMS IN COLORADO

F.W. WHICKER, Colorado State University, School of Veterinary Medicine, *Fort Collins, Colorado* 80521 (AT(11-1)-1156)

Objectives are to study the behavior of certain radionuclides in, and the effects of radiation on, selected organisms and natural ecosystems in north-central Colorado. This research will provide information useful to the safe development of nuclear energy projects and to the study of natural ecosystems and pollution problems. Currently strontium and calcium metabolism is being investigated in captive mule deer (Odocoileus hemionus) by dosing the animals with Sr85, Sr90, and Ca45 and making subsequent whole body counts. The effects of radiation on pikas (Ochotona princeps) are being investigated in captive colonies in which the degree of social competition can be varied. An 8,750 curie Cs137 source is being used to irradiate (both chronically and semi-acutely) a natural grassland community. The structure of the plant community and the distribution of arthropods are under intensive investigation within the radiation field. The kinetic behavior of cesium in a montane, semi-drainage lake is being investigated through techniques of systems analysis in both laboratory and field studies.

Results: Within the past year, significant progress was made on each subproject. Some items of particular interest are (1) Social competition among pikas appears to significantly increase their response to radiation; (2) The short grass plains plant community appears more resistant to ionizing radiation than previously studied community types, and (3) Certain types of mountain lakes appear to recycle cesium from the sediment which causes prolonged higher levels of the nuclide in the biota.

SUPPORTED BY U.S. Atomic Energy Commission

5.0212, EXPERIMENTAL EMBRYOGENESIS AND HISTOGENESIS IN PINUS LAMBERTIANA

G.P. BERLYN, Yale University, Graduate School, *New Haven, Connecticut* 06520 (AT(30-1)-3444)

Objectives--1. Quantitative cytochemical investigations of radiation effects on nucleic acids, proteins and lignification in relation to senescence and cellular death. 2. Investigation of the radiosensitivity of the transport system of Pinus lambertiana Dougl.

Reason--The proposed studies are designed to integrate the molecular and biochemical levels with the cell and tissue level of organization in a quantitative way and to elucidate some of the effects of radiation as revealed at this dimension.

Procedures--The investigations involve the use of autoradiography, tissue culture, interference microscopy, polarizing microscopy, microspectrophotometry, paper & thin-layer chromatography, electrophoresis, spectrophotometry and electron microscopy.

Test Objectives--Embryo explants, tissue slices, callus cultures, and seedlings of Pinus lambertiana grown in culture on chemically defined media.

Results: 1. In a programmed series of radiations it was demonstrated that radiosensitivity was positively correlated with frequency and distribution of cell division. 2. In embryos cultured from seeds that had been irradiated at 10,000 R the cotyledons showed no radiation damage, the hypocotyls showed slight damage, and the roots showed major effects. 3. Free space with S2 layer of tracheid cells was microspectrophotometrically determined to be about 25%. 4. Polar auxin transport and interaction with sucrose was examined during the course of root regeneration in vitro.

5.0213, STUDIES ON THE EFFECTS OF RADIATIONS ON DNA

F. HUTCHINSON, Yale University, School of Medicine, *New Haven, Connecticut* 06510 (AT(30-1)-2653)

The work on this contract studies various lesions produced in DNA by the action of radiations. The dual purpose is to understand the effects of radiations on cells, and to be able to use the lesions formed to learn more about cell biology. The lesion formed by the action of ultraviolet light on DNA containing the base analog bromouracil is being characterized, and at the moment looks as though it will be possible to describe it completely. Specific properties of this lesion are being exploited to be able to photostain selectively DNA containing bromouracil. This property will be used to follow with the electron microscope the process of genetic recombination in bacterial transformation. In a separate line of work the production of double- strand breaks by gamma rays in bacterial DNA is being studied directly. A method has been evolved of extracting very large DNA from cells, and the

breaks are determined by noting the decrease in sedimentation in the ultracentrifuge with increasing radiation dose.

SUPPORTED BY U.S. Atomic Energy Commission

5.0214, CATECHOLAMINE METABOLISM FOLLOWING X-IRRADIATION OF MAMMALS
M.H. VANWOERT, Yale University, School of Medicine, *New Haven, Connecticut* 06510 (AT(30-1))

Total-body X-irradiation is a stress-inducing agent which activates the sympathetic nervous system and produces changes in tissue and urinary levels of catecholamines. The changes in catecholamine metabolism may be important in the physiological response necessary to the survival and recovery from whole-body X-irradiation.

The purpose of this project is to determine the effect of total-body irradiation on the synthesis, release, storage and metabolism of catecholamines after total body irradiation in man and rats. Specific and sensitive techniques will be applied for (a) the assay of endogenous and administered radioactive catecholamines, (b) the determination of pertinent synthetic and degradative enzymes and, (c) the evaluation of pharmacologic agents that influence amine metabolism. These studies should help define some of the mechanisms by which irradiation affects th sympathetic nervous system. This may result in an improved understanding of several features of the acute radiation syndrome, eg. cardiovascular collapse and the neurologic manifestations. Special emphasis will be placed on relating any changes in catecholamine metabolism to the natural radioprotective action of biogenic amines.

Results: Male albino rats were X-irradiated with 1800R and catecholamine content, tyrosine hydroxylase and dopa decarboxylase were determined in the brain and adrenal gland. In the adrenals the epinephrine and norepinephrine decreased simultaneously with a two-fold increase in tyrosine hydroxylase and a 2 1/2 fold increase in dopa decarboxylase activities. There was no change in brain norepinephrine or tyrosine hydroxylase activity. Between 72 and 84 hours after irradiation the brain dopa decarboxylase decreased to 67 percent of control.

The radioprotective action of dopamine in total-body irradiated rats was also investigated. Dopamine (60mg/kg) produced a 50 percent survival time in 30 days; no irradiated controls survived.

5.0215, SPECIFICITY AND INFORMATION TRANSFER IN SENSITIVITY
B.H. WAKSMAN, Yale University, School of Medicine, *New Haven, Connecticut* 06510

Thymus lymphocytes from normal inbred rats or lethally irradiated rats restored with syngeneic or hemiallogeneic bone marrow, will be fractionated on the basis of size and density. In each subpopulation thus obtained, endo and exonucleases will be measured, the cell membrane content of histocompatibility and thymus-specific antigens will be estimated (by immunofluorescence and blast-transformation techniques), and the presence of immunoglobulin will be sought.

In thymectomized irradiated rats, restored with grafts of hemiallogeneic thymus and syngeneic bone marrow (or vice versa), the role of thymus-derived cells in triggering delayed skin reactions will be evaluated (by immunofluorescent identification of cells coming from the thymus graft). In animals stimulated to form antibody of different immunoglobulin classes, a similar identification of thymus-derived vs. marrow-derived cells making antibody will be attempted. Finally in experiments on adoptive transfer of tolerance, the use of similar rats as donors will permit identification of the relative roles of thymus- derived and marrow-derived cells in the induction and/or maintenance of tolerance.

5.0218, THE APPLICATION OF NUCLEAR ENERGY TO AGRICULTURE - RADIOSENSITIVITY OF TROPICAL PLANT SPECIES
C.C. MOH, Inter Amer. Inst. of Agr. Sc., *Turrialba, Costa Rica* (AT(30-1)-2043)

This is a continuous study of radiosensitivity of plant species in the American tropics. The objective is to find out the range of radiosensitivity in the plant families which will provide information for predicting the effect of radioactive fallout on plants in the tropical areas. Plants or seedlings are grown radially from the Cesium- 137 source in the gamma field at Turrialba, Costa Rica, and exposed to a range of daily radiation dose up to 540 r. The criteria for determining the plant sensitivity are: (1) for the asexually propagated species, the maximum daily dose at which the plants can survive for a lengthy period; and (2) for the sexually propagated species, the maximum dose at which the plants can produce seed to complete their life cycle. These criteria would give information on the critical dose level at which a plant species could maintain its continuity in a plant community in case of radioactive fallout.

Results: We have completed the study of several species of gymnosperm (pine, sequoia, cypress, cycad and zamia). In general, the gymnosperms are a very radiosemitive group of plants. For the species in the present study, none could survive at a daily dose of greater than 30 r after more than a year of exposure. This year, the sensitivity of 'Leguminosae' is being investigated. More than 20 species of legumes with diversified botanical characters are being tested in the gamma field.

5.0219, THE APPLICATION OF NUCLEAR ENERGY TO AGRICULTURE: THE MINERALIZATION OF ORGANIC NITROGEN IN SOILS FROM VOLCANIC MATERIAL
C.C. MOH, Inter Amer. Inst. of Agr. Sc., *Turrialba, Costa Rica* (AT(30-1)-2043)

The organic nitrogen mineralization study was concluded. The methods used, Bremner's incubation technique and Jackson's delta value permitted an adequate characterization of the soils studied, which belong to the recent volcanic, lateritic and alluvial groups.

Results: It was observed that soils with over 15% 'crude' allophane present generally a very slow nitrogen mineralization. All but one of the recent volcanic soils belong in this group. Liming reduces mineralization rate while alternate drying and wetting enhances it. The application of organic matter had no clear effect. It is concluded, that total N content can not be used to estimate the N supply in recent volcanic soils.

Part 4 of 10.

5.0220, EFFECT OF RADIATION ON PROTEO-HORMONES ACTIVITY
L. MIKULAJ, Slovak Akademie Ved, *Bratislava, Czechoslovakia*

As is known, hormonal preparations, when used parenterally in medicine for diagnosis or therapy, must satisfy certain requirements as regards sterility. Sterilization by current methods is not always possible because of the change of hormone properties. It is presumed that the use of ionizing radiation for sterilization of hormonal preparations will simplify the working process.

5. RADIATION

The research programme of the Institute of Exper. Endocrinology in Bratislava includes studies on the regulation of endocrine glands function during the processes of adaptation and ontogenesis in experimental animals, of the effect of pituitary trophic hormones on metabolism and hormones biosynthesis in target glands. The role of pituitary hormones and mechanism of their biological action in adaptation to stress is analysed. In these studies the methods for determination of biological activity and bioassay for pituitary hormones, the chromatography, radiochromatography, radioelectrophoresis and radio-immunoassay are employed. All these analytical methods are generally applicable to the study of the effect of radiation on biological and chemical changes of protein hormones. Also included in the work plan for the first year are the following hormones, ACTH, TSH, and STH, which have been selected for the study of the effect of radiation. Their biological and physico-chemical properties will be studied. Electrophoretic and chromatographic purity will be examined too. It is planned to evaluate the co-relation between the changes in biological activity, if these occurred under the action of radiation, and the amount of radiation dose, by the use of statistical-analytical methods.

SUPPORTED BY Intl. Atomic Energy Agency - Austria

5.0221, IDENTIFICATION OF THE RADIOSENSITIVE STAGES DURING THE DIFFERENTIATION OF THE IMMUNOCOMPETENT CELL

J. STERZL, Ceskoslovenska Akademie Ved., *Prague, Czechoslovakia*

The program of the research work is: (a) to irradiate germ-free piglets at various levels to establish the LD/50 and LD/100, (b) to transfer immunocompetent cells to lethally X-irradiated homologous recipients; (c) to determine antibody formation by lymphocytes in culture and by serological techniques; and (d) to study the differentiation of IgM and IgG antibodies at the cellular level and also to determine the differentiation of IgG in situ.

The work will be carried out with the use of sterile piglets, kept on non-antigenic diet, which contain the cells, not yet stimulated by an antigen (immunocompetent X ce'ls). Radioresistance of those animals will be studied before administration of antigen, both in vivo and in isolated cells irradiated in vitro. A similar method will be used for studies of radiosensitivity after a stimulation by antigen, i.e. in the active proliferative phase and in a phase, when the proliferating cells remain prepared for a secondary response as memory cells. Further experiments will follow the effect of irradiation in different time sequences after administration of antigen and the effect of X- irradiation on the ratio of 19S and 7S forming cells (IgM-IgG).

5.0222, STUDY OF INTERNAL CONTAMINATION WITH STRONTIUM-90 AND RADIUM-226 IN MAN IN RELATION TO CLINICAL FINDINGS

V. KLENER, Inst. of Radiation Hygiene, *Prague, Czechoslovakia*

The study is based on long-term observation of 65 persons with internal Ra-226 and Sr-90 contamination, carried out in cooperation with IAEA in Vienna (Research Contract No 107/RB).

Data on the course of Sr-90 retention in the studied group of persons obtained in the period of 920 to 2600 days after exposure shall be supplemented by whole-body counting of Sr-90 and Ra-226 activity and by determination of SR-90 excretion in urine.

The caryologic studies of selected persons will continue. According to the principles of evaluation stated in UNSCEAR 19 the results of the previous examinations during the period of 1962 till 1968 shall be again critically evaluated for detection of aberrations mainly of the stable type (of symmetrical exchanges). Semiautomatic evaluation of the chromosomal picture is being considered.

Contrary to the expected single case of cancer, studies of the previous period ascertained six malignancies of different localisation. The study under preparation will again pay attention to the incidence of malignant tumors. Questionnaires shall be distributed to all persons of the group. The information thus obtained shall help to get special reports from the respective medical establishments. This material shall serve as data for studies of possible changes in the health state of the studied persons especially in respect of follow up of frequency, localisation and histogenetic classification of malignant tumors. On basis of the thus obtained data further examinations shall be proposed in individual cases.

5.0223, PRIMARY PROCESSES IN RADIATION CHEMISTRY OF LIQUIDS AND INTERACTION OF RADIATION WITH BIOLOGICALLY IMPORTANT CHEMICAL SYSTEMS

C.N. TRUMBORE, Univ. of Delaware, Graduate School, *Newark, Delaware* 19711 (AT(30-1)-3383)

Continued studies are proposed on the role of excited electronic states present in irradiated aqueous systems of biological interest. The role of the structure of water itself in the transmission of radiation damage is to be paid particular attention. Correlations between aqueous photochemistry and radiation chemistry are to be sought. Pulse radiolysis and flash photolysis studies of aqueous p- nitrosodimethylaniline are to be continued in an effort to explain the many 'non-classical' anomalies found in the system. Computer calculations are to be continued in an attempt to find a reasonable mechanistic model for a very fast electron decay previously found in nanosecond aqueous pulse radiolysis. Preliminary studies are also proposed in radiation energy transfer in membranes. Fundamental chemical studies are also proposed to seek molecular explanations for the wide variation in radiation sensitivity found for various species of blue green algae.

SUPPORTED BY U.S. Atomic Energy Commission

5.0224, THE ROLE OF STRUCTURE AND ENERGY (OR IONIZATION) TRANSFER IN RADIATION CHEMISTRY AND BIOLOGY

C.N. TRUMBORE, Univ. of Delaware, School of Arts, *Newark, Delaware* 19711 (AT(30-1)-3383)

Purpose: To study the primary physical and chemical processes responsible for the interaction of ionizing radiation with living matter. To study both living systems, such as the blue-green algae, and model systems such as aqueous enzyme-polynucleotide complexes by using analytical techniques of modern biochemistry and physical chemistry. In studies on living systems to observe biochemical differences between cellular fractions from radiation-resistant and radiation-sensitive species as well as to observe differences as a function of added chemical protective agents. To utilize in studies of both living and model systems the fastest possible techniques of flash photolysis and pulse radiolysis in determining the sequence of physical and chemical events following absorption of ionizing or near-ionizing radiation. Finally, to more clearly identify the chemical nature and biochemical consequences of the OH radical in radiation studies.

5.0225, VIRUS INDUCED MUTATION AND IRRADIATION

R.C. BAUMILLER, Georgetown University, School of Medicine, *Washington, District of Columbia* 20007 (AT(30-1)-3905)

Objective and Background: The elucidation of the effects of virus on the genetic material is the broad objective of this project. Specifically the objective is to study the changes in radiation induced mutation in the presence of a given virus and its absence. Radiation and new virus is implicated in point mutation, radiation and now virus is implicated in nondisjunction. Radiation and virus are factors in carcinogenesis. Since both factors have a somewhat similar effect, it is reasonable to believe that their combined effect might be greater than additive. The effect of different viruses in different populations may account for epidemiological variation in types of cancer and even in frequency of chromosome abnormalities. The genetic hazards of radiation may be correlated with the viral background present. Procedure: Drosophila melanogaster, infected with sigma virus and 'isogenic' sigma virus free lines is the basic test material. Various types of infection (stable and unstable) and genetic backgrounds are available. Basic

techniques for studying mutation frequency are widely known in this organism. Virus induced x chromosome recessive lethals are found in both the male and female germ line. These mutants are primarily at the distal end of the chromosome (0.0-25 map units). The rate of nondisjunction in the female germ line, as evidenced by the presence of matroclinus females, is significantly higher in virus containing line than in an 'isogenic' virus free line. Results of experiments utilizing X-rays and virus presence are consistent with the hypothesis that their combined effect is greater than additive for point mutants, nondisjunction and sterility.

5.0226, IRRADIATION AND TISSUE-LOCALIZING RESPONSE

R.L. KAHN, Howard University, School of Medicine, *Washington, District of Columbia* 20001

It is a paradox that the very mechanism of the extraordinary local healing effect of radiation therapy in cancer may contain the seed of ultimate morbidity. This possibility is based on our observation that X-irradiation has an antilocalizing or spreading effect on tissue- injected substances. Bacteria, protein or toxin injected in the normal skin of rabbits become localized to a given degree, but if injected in an irradiated area of the skin, they escape from the injected area and reach the blood stream. Might this antilocalizing effect of irradiation permit in certain instances the escape of cancer cells from a cancer- irradiated area and lead to metastasis? Locally, the healing of the irradiated area both in cancer and in infection is so outstanding that physicians speak of irradiation as being anti-inflammatory. Indications are that the reason for the local anti-inflammatory action is that the irradiation exerts an antilocalizing effect. Antilocalization: 1) Permits the spread of injurious substances (bacteria or toxin) from the irradiated area before they can produce local injury, 2) causes a breakthrough of fresh blood supply to the area and 3) enables dead cells and debris to be carried off from the area. Each of these aspects is of an anti-inflammatory nature. To prevent the escape of cancer cells following radiation therapy of cancer is the basic aim of this research project herein proposed. The plan is to investigate the mechanism of antilocalization following irradiation. This plan would embrace also studies of the mechanism of tissue localization in immunity in the absence of irradiation. It is proposed also to combine irradiation of cancer in animals with anticancer drugs as a means to prevent metastasis and to study this problem in conjunction with attempts to combine irradiation of infection in animals with the use of antibiotics.

5.0227, LATE EFFECTS OF RADIATION ON THE POPULATIONS OF HIROSHIMA AND NAGASAKI - BASIC RADIATION ESTIMATES

UNKNOWN, Natl. Academy of Sciences, *Washington, District of Columbia* 20037 (AT-30-1-72)

This component of the unified program comprises investigation of basic doses of radiation from atomic bombs received by the populations of Hiroshima and Nagasaki, as well as radiation received from diagnostic and therapeutic X-ray procedures or other possible contaminants.

The calculation of radiation dose received by persons exposed to the bombs requires determination of air dose curves, distance from the burst and attenuation factors of shielding materials. In collaboration with the Health Physics Division of the Oak Ridge National Laboratory studies are being made concerning a revised air dose curve (T65D) and new T65D transmission calculation methods while shielding studies describe the shielding environment of persons who were within houses of typical Japanese construction.

Calculation of possible contaminant radiation dosages received outside ABCC comprises several phases, the first being the interrogation of persons in the study population to determine where and how frequently they received medical X-ray. The second phase concerns verification of exposures reported by the subjects and a determination of the technical factors in such exposures. The third phase is determination of individual subject doses received and to evaluate the contribution of this dose to the overall radiation exposure.

SUPPORTED BY U.S. Atomic Energy Commission

5.0228, LATE EFFECTS OF RADIATION ON THE POPULATIONS OF HIROSHIMA AND NAGASAKI - POPULATION STUDIES

UNKNOWN, Natl. Academy of Sciences, *Washington, District of Columbia* 20037 (AT-30-1-72)

This component of the unified program is intended to provide socio- economic and other background material for use in analysis of data. One phase of the program is an epidemiological survey of the Adult Health Study sample to develop a reservoir of environmental data on this selected population. Although the radiation groups are matched for age and sex there are other known differences so that analysis of the morbidity and mortality data will require epidemiological evaluations. This study is therefore designed to compile information concerning residential history, military service, occupational and marital history, smoking and drinking, dietary habits, socio-economic status, religion and education.

A second study is an epidemiologic field study of leukemia in both cities in an attempt to determine if a relationship exists between various types and incidence of the disease and environmental factors such as exposure to X-ray at various stages of growth, various genetic factors such as blood type and ear-wax type or other factors not associated with radiation. A case history probe and study of selected cases from the ABCC leukemia register is the general method of approach.

SUPPORTED BY U.S. Atomic Energy Commission

5.0229, LATE EFFECTS OF RADIATION ON THE POPULATIONS OF HIROSHIMA AND NAGASAKI - GROWTH AND DEVELOPMENT STUDIES

UNKNOWN, Natl. Academy of Sciences, *Washington, District of Columbia* 20037 (AT-30-1-72)

This component of the unified program comprises two main areas. The first is related to experimental evidence that radiation accelerates aging. The following indices are being tested in relation to aging and radiation exposure: a one hour glucose challenge; measurement of the Achilles tendon reflex by Burdick Photomotograph; an investigation of the soluble to insoluble collagen ratio in skin from autopsies and a morphologic evaluation of aging using such indices as amount of lipofuscin in the heart, size of hepatic nuclear, number of PAS-positive spleen cells and other age-related tests.

The second area of study concerns determination of possible differences in growth and development in two distinct groups of children included in other current study samples. These subjects comprise (a) all persons in the Adult Health Study who were age 0 to 10 years at the time of bombing plus (b) all children of the 'in utero' exposed matched sample. Former studies of growth and development have led to uncertain conclusions, in part because of inadequate evaluation of the influence of socio-economic differences and loss of family, therefore data on this factor is being obtained and considered in the analysis together with radiation dose, age at time of exposure and sex.

SUPPORTED BY U.S. Atomic Energy Commission

5.0230, LATE EFFECTS OF RADIATION ON THE POPULATIONS OF HIROSHIMA AND NAGASAKI - MORTALITY STUDIES

UNKNOWN, Natl. Academy of Sciences, *Washington, District of Columbia* 20037 (AT-30-1-72)

This component of the unified program comprises statistical and pathologic investigations of the study population to determine the effects of exposure on life span and to provide through post-mortem examination the identification and evaluation of cause of death. Current statistical studies are: the Life Span Study (ST-100) to determine whether those of the approximately 100,000 persons who were residing in Hiroshima and Nagasaki at the time of the 1950 Japanese National Census who escaped death from acute effects of the bombs continue to live as long as the non-exposed and whether shortening of the life span, if any, is a function of radiation dose; study of children born to survivors comparing mortality rate of children of heavily exposed parents

and suitable controls, study of mortality in children exposed in utero and a study of mortality and socio-demographic characteristics of survivors.

The pathology studies deal with precise diagnosis of disease evident in medical studies, the incidence of various disease processes and with cytologic and histologic changes attributable to radiation. The population sample is the ST-100 sample described above. Post-mortem examinations are performed on as many of the deceased members of the sample as are offered by the families. At present there are approximately 1,000 deaths in the ST-100 sample each year and of these 40% - 50% are autopsied at ABCC.

SUPPORTED BY U.S. Atomic Energy Commission

5.0231, LATE EFFECTS OF RADIATION ON THE POPULATIONS OF HIROSHIMA AND NAGASAKI - MORBIDITY STUDIES

UNKNOWN, Natl. Academy of Sciences, *Washington, District of Columbia* 20037 (AT-30-1-72)

This component of the unified program is concerned with the relation of ionizing radiation to the incidence of disease in the study populations. A major phase of this program is the Adult Health Study which is an intensive search for late effects of single whole body irradiation from the Hiroshima and Nagasaki bombs. Observations are made by means of biennial basic routine medical examinations of the study population which totals approximately 20,000 persons in both cities including non-exposed controls matched by age and sex.

The leukemia detection survey is designed to detect, diagnose and evaluate all cases of leukemia and certain related hematologic disorders in both cities using the broadest possible population and diagnostic bases.

Field studies on the health status of survivors are intended to provide information on significant illnesses which occur in the Adult Health Study sample and provide information on state of health of patients who do not undergo examination at ABCC.

The Tumor Registry provides, through reports of local physicians and medical records of the principal hospitals, data on tumors which can be analyzed within the framework of the ABCC population samples.

SUPPORTED BY U.S. Atomic Energy Commission

5.0232, LATE EFFECTS OF RADIATION ON THE POPULATIONS OF HIROSHIMA AND NAGASAKI - SPECIFIC DISEASES OR DISORDERS STUDIES

UNKNOWN, Natl. Academy of Sciences, *Washington, District of Columbia* 20037 (AT-30-1-72)

This component of the unified program comprises studies of specific diseases or disorders which are observed in the Adult Health Study or the pathology studies and which merit detailed investigations. Current studies are composed of the following subprojects: Arthrologic - Rheumatoid Arthritis and Gout; Cardiovascular - Analysis of Norms for QRS Voltage, Cardiovascular Diseases Study, Predictive Significance of a 'Positive' Master's Exercise ECG Test, Hematologic - Quantitative Serum Protein Electrophoretic Study of Possible Effects of Radiation and Selected Diseases, Aplastic Anemia, Serum Immunoglobulin Levels, The Granulocyte Response to Stress as a Measure of Functional Bone Marrow Reserve in Atomic Bomb Survivors, Hiroshima, Immunologic - Australia Antigen in Atomic Bomb Survivors, Metabolic - Appraisal of Diabetes Mellitus Using Insulin Immunoassay; Neoplastic - Field Study of Leukemia, Blood Group and Haptoglobins in Leukemia, Polyps and Carcinomas of Stomach, Small and Large Intestine, Malignant Lymphoma and Multiple Myeloma, Multiple Neoplasms in Autopsy Series, Carcinoma of Liver, Gallbladder, and Biliary Tree and Their Relationships to Ionizing Radiation, Cirrhosis and Gallstones, Pathology Study of Gastric Carcinoma, Bronchogenic Carcinoma, Pathology Study of Malignant and Benign Breast Diseases and Their Relation to Radiation, Leukemia in Offspring of Atomic Bomb Survivors 1946-68.

SUPPORTED BY U.S. Atomic Energy Commission

5.0233, LATE EFFECTS OF RADIATION ON THE POPULATIONS OF HIROSHIMA AND NAGASAKI - GENETICS STUDIES

UNKNOWN, Natl. Academy of Sciences, *Washington, District of Columbia* 20037 (AT-30-1-72)

This component of the unified program is concerned with genetic effects of radiation on the populations of Hiroshima and Nagasaki. It consists of cytogenetic studies involving cell cultures, analysis by other laboratory methods of genetically connected diseases or aberrations and statistical studies. Current studies are: cytogenetic study of individuals with congenital diseases or malformation by means of tissue culture of peripheral leukocytes; somatic cell chromosome analysis consisting of examination of peripheral leukocyte chromosomes of persons who received heavy exposure (500 to 1000 plus rad); study of patterns of cell division and chromosome replication in human cells consisting of comparison of mitotic capacities and patterns of chromosome replication in cells from normal subjects and from patients with hematologic disorders; a cytogenetic study of the offspring of atomic bomb survivors to detect balanced chromosomal rearrangements in the progeny induced in parental germ cells by radiation; a study of blood groups in Adult Health Study and in utero subjects to determine phenotype frequencies for certain blood group antigens; cytogenetic studies of tissue obtained at autopsy; sex-ratio in offspring of In- Utero exposed and clinical characteristics of A-bomb survivors with chromosomal aberrations.

Results: 1. Aberrant karyotypes and spontaneous abortion in a family. (Kadotani et al) TR 5-69, March, 1969. 2. Familial occurrence of a short arm deletion of a G-group chromosome. (Yoshida, Honda) TR 10- 69, April, 1969. 3. Chromosome aberrations and malignant disease among A-bomb survivors. (Bloom et al) TR 2-70, March 1970.

5.0234, A STUDY OF THE BIOCHEMICAL EFFECTS OF IONIZING AND NONIONZING RADIATION ON PLANT METABOLISM DURING DEVELOPMENT

W.H. KLEIN, Smithsonian Institution, *Washington, District of Columbia* 20560 (AT(30-1)-2373)

Three areas of investigation have been pursued: A) direct effect of light upon phytochrome, B) measurement of daily and seasonal fluctuations in spectral distribution of total sky irradiance and its control of plant growth and development, and C) cytogenetic effects of radiation on plants.

A) Experiments are proposed as follows: 1) determine the amino acid sequence and the protein-chromophore linkages of phytochrome, 2) study disaggregation of phytochrome under controlled conditions and the effect of this disaggregation upon spectrophotometric properties of phytochrome.

B) Experiments are proposed as follows, 1) determine the changes in spectral quality during twilight hours through the implementation of more sensitive detector systems, 2) acquire a full set of solar energy measurements at 2 different latitudes (i.e. Israel and Washington, D.C.).

C) Experiments are proposed as follows; 1) determine the environmental conditions (in newly designed controlled environment chambers) necessary to obtain consistently viable pollen and reproducible chromatid aberration rates, the number of chromatid aberrations and/or the ratio of the chromatid exchange will be used as indices of irradiation effects.

Results. From chromophore degradation studies the bile type chromophore appears identical in the PR form with that of phycocyanin. The structure of the I ring is modified in the PFR form of phytochrome. A scheme for covalent linkage is proposed for both forms of phytochrome bile pigment. A trace-metals analysis has been initiated.

On clear days the ratio of red/far-red remains above 1.5 while on cloudy days (90 per cent reduction in total radiant energy) the ratio shifts toward far red-red and oscillates between 0.5 and 1.5.

5.0242, AFRRI RADIATION CHEMISTRY PROGRAM
J.E. LEISS, U.S. Dept. of Commerce, Natl. Bureau of Standards, *Washington, District of Columbia* 20234

The objective is to permit utilization of the NBS electron linear accelerator facility by representatives of the Armed Forces Radiobiology Research Institute to conduct pulse radiolysis investigations. The role of deoxyribonucleic acid (DNA) in the processes of cell replication and metabolism has been emphasized in recent years. A single molecule of DNA carries in its double helical structure the genetic information necessary for the continued life of the cell. It appears that DNA is a primary target of ionizing radiation and that much of the lethal injury sustained by an irradiated cell is a consequence of permanent changes induced in the unique structure of the genetic material. The purpose of this investigation is to study the transient radiation chemistry of aqueous solutions of DNA and related biological polymers with particular emphasis on the mechanism of radiation damage at the molecular level. The role of free radical and electron scavengers as possible protective agents for animal systems will also be examined.

The Bureau will construct and install on the NBS linear accelerator facility those additional beam handling components and apparatus required to allow the AFRRI investigations to be carried to completion. The apparatus constructed will consist partially of equipment presently available at NBS, plus additional components specifically required for this project. The work will be carried out in close collaboration with a member of the Applied Radiation Division, insofar as the equipment will be used in both AFRRI and projected NBS experiments. Reliable apparatus should be ready for installation in the Linac facility by early July 1969.

The expected output is an understanding of the mechanisms of protection and repair in cellular material exposed to ionizing radiation, based on new information about the primary structural changes in DNA.

SUPPORTED BY U.S. Dept. of Commerce - N.B.S.

5.0243, ATLAS OF RADIATION PATHOLOGY
D.C. WHITE, U.S. Dept. of Defense, Armed Forces Inst. of Path., *Washington, District of Columbia* 20305 (AT(49-7)2666)

Many excellent informative publications relate to injuries produced in mammalian tissues by the actions of ionizing radiation. Few, however, are concerned with the detailed histopathology and its correlations to the characteristics of the imposed irradiation. It is the purpose of this Atlas of Radiation Pathology to present, by means of high-resolution photo-micrographs, appropriately identified and described, such characteristic alterations in mammalian tissues. This will be augmented by concise and comprehensive discussions of the kinetics of radiation pathology and the employment of charts, diagrams, and stylized drawings emphasizing specific aspects of this injury. This Atlas will provide histologic guidelines assisting the pathologist, radiobiologist, and radiation therapist, in the proper interpretation of presumed radiation-induced injuries. The material utilized in the development of this publication is derived from the files of the Registry of Radiation Pathology of the Armed Forces Institute of Pathology and, therefore, is representative of a large volume of carefully reviewed and documented human cases selected for the characteristic responses to known radiation exposure - predominantly therapeutic by intent. Both surgical and autopsy materials are included in the specimens described and photographed and

the effects to be considered range from the prompt and dramatic degenerative changes in the rapid cell-renewal systems as with a single, whole-body, high-dose exposure to the delayed scarring, atrophy and dysplasia following extensive, protracted radiation therapy.

Results: That segment of the Atlas dealing with lethal acute whole-body exposures has been completed. Five human fatalities are described and illustrated in detail with particular emphasis on the rapidly developing degenerative responses in critical body systems.

5.0244, ALTERATION INDUCED BY X-RAY & ULTRAVIOLET LIGHT ON THE SYNTHESIS & MAINTENANCE OF MACROMOLECULAR COMPONENTS WITHIN MICROORGANISMS

D. BILLEN, Univ. of Florida, School of Medicine, *Gainesville, Florida* 32601 (AT-(40-1)-3596)

The relationship between effects of radiation on DNA and DNA replication and cell survival is being studied. Both radio- and heavy isotopes are being used in the study, employing primarily bacterial cells and their chromosomes. The following projects are underway: a) Characterization of the DNA repair synthesis system vis a vis normal DNA replication and effects on methylation pattern. b) The nature and consequence of new initiation sites induced by irradiation, especially ionizing radiation. c) The replicative fate of DNA following its first cycle of post-irradiation replication. d) Factors responsible for physiologically determined radiosensitivity. e) The effect of radiation and modifying agents on phiX174 DNA.

Results: Qualitative differences in DNA and DNA synthesis regulation, following UV or X-irradiation, have been observed. Three such differences involve: a) Premature initiation of rounds of DNA replication, as seen in UV exposed cells; or unusual initiation sites for DNA synthesis as seen following X- or gamma-irradiation. b) Incomplete replication of DNA during the initial post-irradiation cyles. c) Alteration in the number of cytosine and adenine residues of DNA that are transmethylated following UV exposure

5.0245, A CYTOLOGICAL STUDY OF RADIATION INDUCED ALTERATIONS IN CYTOPLASMIC FACTORS CONTROLLING MALE STERILITY IN CORN

J.R. EDWARDSON, Univ. of Florida, Agricultural Experiment Sta., *Gainesville, Florida* 32601 (AT-(40-1)-2583)

Objectives of this investigation are to detect cytoplasmic sterility factors with electron microscopy and to determine whether sterility factors can be inactivated or induced by gamma radiation. Techniques employed in cytology of plant viruses are being applied to electron microscopy of meristems, leaf tissues, and embryo sacs in cytoplasmic male sterile and maintainer corn, sorghum, petunia, and Crotalaria. Cytological studies of the fertilization process in these lines are in progress. An irradiation program is being initiated in an attempt to inactivate the cytoplasmic factor(s) controlling susceptibility to 'Helminthosporium maydis' in T-type corn. Cytological studies of virus induced cytoplasmic inclusions are continuing in order to obtain information on their structure, composition and relationships to host tissue.

Results: Viruses of the PVY-group have been found to induce cylindrical inclusions in the cytoplasms of different host genera. These inclusions are useful in diagnosing infections by members of the PVY group of viruses. Inactivation of sterility factors is indicated by the occurrence of fertile progenies obtained from irradiated T-type sterile corn. Hybrids in T-type cytoplasm exhibit less radiation damage than do their counterparts in normal cytoplasm.

5.0246, EFFECTS OF GAMMA RADIATION AND DIETARY DEFICIENCIES ON THE PLACENTAL TRANSFER OF MINERALS

J.P. FEASTER, Univ. of Florida, Agricultural Experiment Sta., *Gainesville, Florida* 32601 (FLA-AL-01044)

OBJECTIVE: Determine the effects of gamma radiation and/or dietary deficiencies on the rate and extent of placental transfer of certain mineral elements.

APPROACH: Under this project, transfer of radioactive forms of minerals (iron, cobalt, copper, manganese, and iodine) across the placenta of pregnant cattle and swine will be measured, a comparison of rate of transfer being made between animals on complete diets and those on diets deficient in mineral elements or protein. Females will be studied at various stages of pregnancy to determine possible periods of increased fetal demands for the mineral elements. In the radiation phase, placental transfer in animals receiving 200 to 400 R whole-body gamma radiation will be compared with transfer in non-irradiated females.

PROGRESS: The effects of diets deficient in copper (Cu) or zinc (Zn) and containing pesticides (DDT, Parathion and Sevin) at low levels on pregnant rats have been studied. In the study with Cu, feeding a diet inadequate in Cu did not affect weight gains of growing rats, but did significantly reduce levels of Cu in livers. Pesticides reduced weight gains in growing rats fed both adequate and low Cu diets, though not significantly. Neither reproduction nor hemoglobin levels were affected by Cu level or pesticides in the diet. In rats ingesting only DDT normally present in dietary constituents, low Cu intake significantly reduced storage of DDT in adipose tissue. In the study with Zn, neither a low Zn diet nor pesticides adversely affected weight gains, reproduction, or hemoglobin levels in maternal rats, or hemoglobin levels in full-term fetuses. A high Zn diet (7000 ppm compared to 50 ppm in controls) reduced weight gains and resulted in reproductive failure in nearly one-half the females. Fetuses which went to term, were small and showed significant reductions in hemoglobin levels. Feeding the low Zn diet significantly increased the uptake of radioactive Zn by red blood cells, indicating increased retention of available Zn by the deprived rats. Recent findings from a previous study show DDT present in fetal livers, proving that it is transferred across the placenta during pregnancy. It can be concluded that chronic low-level intake of pesticides does not adversely affect pregnant rats, even under the stress of Cu or Zn deprivation.

5.0247, THE EFFECTS AND MECHANISMS OF ACTION OF IONIZING RADIATION ON THE HOUSE FLY MUSCA DOMESTICA

M. ROCKSTEIN, Univ. of Miami, School of Medicine, *Miami, Florida* 33124 (AT-(40-1)-3862)

This is a continuation of a study on the effects and mechanisms of action of ionizing radiation on the house fly, Musca domestica L., particularly as regards the locomotor function of flight. Completion of a current study on the effects of high-energy irradiation effects of the pupal stage upon the flight ability of successfully-emerging adult flies is expected during the current year, as well as initiation of further studies on the effects of such irradiation on the age-related distribution of enzymes and substrates concerned with contraction of flight muscle.

5.0248, LASER SAFETY IN MILITARY TRAINING DEVICES

D.R. BREGLIA U.S. Navy, Training Device Center, *Orlando, Florida*

Technical Objective: Utilizing state-of-the-art data on skin and retinal cell damage, energy or power threshold calculations and experiments will be performed to determine the type of laser to be used in specific military training systems which require direct trainee observations of, or exposure to, laser radiation.

SUPPORTED BY U.S. Dept. of Defense - Navy

5.0249, EFFECTS OF MICROWAVE RADIATION ON NAVAL PERSONNEL
D.E. BEISCHER, U.S. Navy, Aerospace Medical Res. Lab., *Pensacola, Florida* 32512

Technical Objective: Excessive exposure of Naval personnel to microwave radiation is an acute problem. Even low doses may reduce the efficiency of personnel in vital duty positions. The maximum safe exposure level presently endorsed by all branches of the armed forces (10 mw/sq cm) is based mainly on extrapolation from animal experimentation and does not take into account transmitter frequency or length of exposure. The great uncertainty in setting safe limits is best illustrated by the wide gap between U.S. and Soviet limits, with the U. S. limit higher by a factor of 1000 than the USSR level. Present and future use by the Navy of microwave generators of increasingly higher power at multiple frequencies makes it appear mandatory to experimentally establish safe levels using human subjects.

SUPPORTED BY U.S. Dept. of Defense - Navy

5.0250, THE EFFECTS OF EXTREMELY LOW FREQUENCY (ELF) RADIATION ON MAN
D.E. BEISCHER, U.S. Navy, Aerospace Medical Res. Lab., *Pensacola, Florida* 32512

Technical Objective: ELF radiation will perform a major role in the Navy's worldwide communication system. An urgent need exists for information on the physiological and psychological effects of this radiation on man at the exact frequencies of a considered Navy communication system. No published biological information is available at these specific frequencies, but studies at 10, 50, and 60 hz may serve as guidance. The results of a systematic and controlled exposure of human volunteers in the laboratory and in the field will substantially influence the deployment of the final technical communication system and contribute to alleviate the fears of an environmental radiation hazard to the population near the emitter site.

SUPPORTED BY U.S. Dept. of Defense - Navy

5.0251, PERFORMANCE IN NONHUMAN PRIMATES AS INFLUENCED BY LOW FREQUENCY ELECTROMAGNETIC FIELDS
J.O. DELORGE, U.S. Navy, Aerospace Medical Res. Lab., *Pensacola, Florida* 32512

Technical Objective: The primary objective is to make an extensive experimental analysis of numerous operant behaviors in a nonhuman primate, Macaca mulatta, under the influence of low intensity, low frequency electromagnetic fields in order to determine if there are effects and if the effects facilitate or deteriorate animal behavior analogous to human behavior. A secondary objective is to discover if the fields will function as a stimuli for a behavioral measure of arousal. The accomplishment of these objectives will help ascertain the ecological feasibility of an extremely low frequency naval communication system.

5.0252, ISOLATION AND IDENTIFICATION OF THE HEMOPOIETIC STEM CELL
R.C. LEIF, Florida State University, Graduate School, *Tallahassee, Florida* 32306 (AT(40-1)-2690)

There are now very strong indications that not all of the colony forming units of Till, which give rise to colonies in the spleens of irradiated hosts, are truly effective in providing long term radiation survival. It is proposed to fractionate these mouse bone marrow cells with the bovine serum albumin gradient technique of Leif and Vinograd and to utilize both long term survival and the permanent introduction of a new type of hemoglobin into chronically anemic mice as assays. It is now possible by Centrifugal Cytology to prepare artifact free dispersions of the fractions of mouse marrow cells obtained from these separations on conventional microscope slides. An attempt to identify the radiation survival cell by correlation of its density distribution with that of the various morphological classes of cells will be undertaken. Further purification of the stem cell will be possible by other techniques such as sedimentation and liquid curtain electrophoresis. It will be possible to assay these fractions by the simpler colony forming assay of Till, because any cells yielding spurious results will have been previously eliminated by the prior buoyant density separation.

Results: The technique of Centrifugal Cytology has been developed and interfaced with the albumin density gradient technique. Human blood, and rat and guinea pig bone marrow cells have been successfully separated by the gradient technique and benzidine geisa stained slides prepared from the density fractions. Preliminary histological analysis of the slides indicates that: buoyant density is directly related to maturation, blast cells can be separated from mature forms, many cells like mature megakaryocytes are contained in only one of 28 density fractions of differing cellular composition resolvable by the gradient.

5.0253, RADIATION INDUCED FREE RADICALS AND RADICAL PAIRS
G.C. MOULTON, Florida State University, School of Arts, *Tallahassee, Florida* 32306

The primary products produced by irradiating organic compounds of biological importance with 3 MeV X-rays, 50 kv X-rays, high speed electrons, or ultraviolet radiation at low temperatures will be investigated. The free radicals and radical pairs produced by the radiation will be detected and analyzed using electron spin resonance, and Endor techniques.

By working at low temperatures, 77 degree K or 4.2 degree K, we hope to be able to trap the primary radicals in a greater percentage of cases and thereby gain a better understanding of the fundamental irradiation effects. We will study single crystals mostly, since considerably more information can usually be obtained from single crystals than powders or amorphous materials. We expect to study amino acids primarily and eventually proteins.

Subsequent to the production and identification of the primary products, we will study the resulting products and the kinetics of the reaction when a sample is warmed slowly to room temperature. In addition to this, the same compound and related compounds will be irradiated with different kinds of radiation, at different dose rates, irradiated in vacuum or in the presence of oxygen, etc., in order to try to determine the importance of these variables in the radiation reactions. It is hoped that a thorough understanding of the fundamental mechanisms in free radical reactions in simple systems should ultimately help in the construction of molecular models of free radical reactions in biological systems.

5.0254, THE STUDIES OF IONIZING RADIATION AS STIMULI
J.C. SMITH, Florida State University, Graduate School, *Tallahassee, Florida* 32306 (AT(40-1)-2690)

The studies of ionizing radiation as stimuli to rats, pigeons and monkeys will be continued. Investigations will be conducted studying the immediate response of these animals to X-ray and Gamma ray stimulations using the modified conditioned suppression technique. Special emphasis will be placed on measurement of the minimum pulse duration and dose rate that can be used in training the subjects. Further studies will be conducted studying the role of olfactory sensitivity in X-ray detection.

Additional studies will be run to use both X and Gamma rays as noxious stimuli in taste aversion studies. Emphasis will be placed on the effects of these exposures at different times during the circadian cycle. Attempts will also be made to quantify the strength of these taste aversions using operant conditioning techniques.

5.0256, MECHANISM OF DIVALENT ION ABSORPTION
H.M. EDWARDS, Univ. of Georgia, Agricultural Experiment Sta., *Athens, Georgia* 30601 (GEO-03-0345)

OBJECTIVE: Determine the influence of calcium level of the diet, zinc level of the diet, and phytic acid of the diet on zinc-65 absorption and excretion. Determine the effect of age, sex and germ free vs contaminated environment on zinc-65 absorption and excretion. Determine the influence of several chelating agents on the absorption, excretion and transport of zinc-65. Determine how orally absorbed zinc- 65 proceeds from the intestine to the tissues.

APPROACH: All absorption and excretion studies will be conducted by utilizing a gamma emitting radioisotope and a whole body counter. Very satisfactory isotopes of zinc, cobalt, iron and manganese are available. All procedures and initial investigations of problems will be investigated utilizing zinc-65.

PROGRESS: The effects of feeding high levels of different elements on the absorption of Co, Fe, Mn and Zn were investigated. Feeding high levels of cobalt, iron, manganese and zinc resulted, in general, in lower absorption and reduced biological half-life of their isotopes, possibly due to a faster metabolism of the elements in the body or to specific homeostatic control for the amounts of each element present in the body. An interaction between zinc and cadmium or mercury was clearly shown, as evidenced by the decrease of Zn absorption and the increase of zero-day retention values. Iron, also, depressed the absorption and increased the retention at zero-days of Zn, and zinc increased Fe absorption, indicating some type of relationship between these elements. The increase in the absorption of Fe and Co when high levels of nickel were added to the diet, were not statistically significant. Studies on Se absorption indicate that chickens between the ages of 2 and 23 days were very efficient in absorbing Se (83 to 100% absorption). Addition of sulfur, tellurium and arsenic to the ration did not greatly influence the absorption or retention of Se. Increasing the levels of supplemental selenium in the diet (0.12ppm to 15.78ppm) caused a decrease in Se absorption and a decrease in the biological half-life of Se in the chicken.

5.0257, AN EVALUATION OF THE FACTORS INVOLVED IN BIOACCUMULATION OF GAMMA EMITTING RADIONUCLIDES IN WILD DEER
J.H. JENKINS, Univ. of Georgia, School of Forestry, *Athens, Georgia* 30601 (AT-(40-1)-3905)

Objectives: To determine 1) the amounts and kinds of gamma emitting radionuclides in an important wildlife species the white-tailed deer (Odocoileus virginianus) in the Southeast: 2) elucidate some of their food chains the year around, and 3) see if a relationship exists between bioaccumulation in deer, the soils, the deer foods available, and the rumen contents.

Scientific background: Three whole body counters have been constructed to measure the gamma rays emitted by animals varying in size from warblers (10 grams) and cotton rats (100 grams) up through seventy- five pounds (Coyotes taken in the wild in Georgia have been counted). It has been well known since 1963 that certain arctic animals contain relatively high amounts of radioactivity. There are some comparable situations in some habitats in the Southeast.

Proposed procedure: We shall analyze deer on systematic basis by physiographic province and season in the Southeast to determine the amounts and kinds of isotopes present. Emphasis will be placed on correlation of food intake through analysis of rumen contents and the known food habits of the deer in the areas involved. These facts will be compared with the soil characteristics.

Results: Over 500 deer have been analyzed. Deer from the southeast often have body burdens of Cesium-137 that exceeded those reported from Alaskan caribou at their peak. High Cesium-137 levels are restricted to the Lower Coastal Plain region of the Southeast and the extent within this province has now been delineated. Only Cs137 and K40 were detected in muscle tissue. On most study areas deer reach their peak concentration in winter but on a few areas they have peaked in late summer. Rumens have been analyzed from 135 deer. The factors involved in bioaccumulation are being elucidated.

SUPPORTED BY U.S. Atomic Energy Commission

5.0258, AN EVALUATION OF RADIOACTIVE CONTAMINANTS IN WILD ANIMALS OF FOREST LANDS
J.H. JENKINS, Univ. of Georgia, Agricultural Experiment Sta., *Athens, Georgia* 30601 (GEO-0020-MS)

OBJECTIVE: Determine radioisotopes in selected mammals, birds and other wildlife species. Determine food chain interrelationships between the predators, herbivores, and omnivores. Determine the whole body burden of radiation that the more common species in the above classifications are receiving and the probable effects as now known. Relate the above conditions to domestic animals and man.

APPROACH: Surveys of wildlife species would be made as to their gamma emitting radionuclides (the whole body burden) and their methods of acquiring these would be elucidated and their health significance both to the animals involved and to man would be evaluated. Preliminary data have already been obtained from over 200 specimens taken in this area. These data show several interesting and puzzling interrelationships.

PROGRESS: We are now pinpointing the radiation accumulation areas. We analyzed 383 deer from the Southeast by requesting the Game and Fish Commissions to save a sample from all road kills. This was suggested to us by the U. S. Public Health Service. We know now about where and when radioactivity occurs in deer from fallout biomagnification. We also check deer from 6 locations every 3 months. We have found that Cesium 137 accumulation can sometimes be high in bobcats, raccoons, squirrels, and a few fish species. In general, birds accumulate very little radioactivity. Some wildlife species have a body burden over 300 times that of beef in the Southeast. It is doubtful that wildlife poses much hazard to people since we do not depend on it ordinarily as a steady food source. We should definitely know the mechanics involved in bioaccumulation. Stomach contents of 135 deer were analyzed for radiation. We checked over 200 plant specimens and have taken over 60 soil samples. Work is continuing to ascertain the bioaccumulation factors.

SUPPORTED BY U.S. Dept. of Agriculture

5.0259, RADIOLYSIS OF HETEROGENEOUS SYSTEMS
F.J. JOHNSTON, Univ. of Georgia, Graduate School, *Athens, Georgia* 30601

Studies of the effects of ionizing radiation on colloidal sulfur suspensions having narrow particle size distributions are being continued. Aqueous suspensions and organosols will be studed by light scattering, spectrophotometric and conductometric methods. Our results to this time suggest that the sulfur particles act as 'sinks' for reactive intermediates produced by the radiation in the aqueous phase.

Radiation effects in other systems of known particle size and concentration will be measured.

Efficiencies of energy transfer from irradiated solid adsorbents to adsorbed inorganic gases are being determined.

5.0260, ECOLOGICAL AND RADIO-ECOLOGICAL INVESTIGATIONS AT THE AEC SAVANNAH RIVER PLANT
E.P. ODUM, Univ. of Georgia, Inst. of Ecology, *Athens, Georgia* 30602 (AT(38-1)310,)

Research carried out by University of Georgia and visiting ecologists at the Savannah River Ecology Laboratory is grouped under the following general programs: (1) structure and function of ecological systems, (2) use of radionuclides to measure ecological processes, (3) effects of radiation on ecological systems, (4) effects of thermal enrichment on aquatic ecosystems. During the past years considerable progress was made on 56 subprojects. Thirty-one publications under the contract appeared in the literature, 16 more are in press, 6 are submitted for publication, and 45 were read at scientific, professional and social meetings by members of the staff. Continued use was made of the 10,000 curie 137-Cesium source to irradiate poultry, small mammals, reptiles, and a litter-soil ecosystem. With the declassification of the water temperatures in the Par Pond, seven studies dealing with aquatic organisms living in thermally enriched water were initiated. The extensive thermal gradient within the lake makes these studies of particular interest. New programs in mineral cycling and avian bioenergetics got under way and emphasis in the mammal program shifted to methods of determining absolute density. The drift-fence/pit-fall trap method proved particularly successful in determining migration patterns in reptiles and amphibians.

SUPPORTED BY U.S. Atomic Energy Commission

5.0261, EFFECTS OF RADIATION ON PLANT AND ANIMAL COMMUNITIES
R.B. PLATT, Emory University, School of Arts, *Atlanta, Georgia* 30322 (AT-(40-1)-2412)

This program is now in its fourteenth year and is concerned with population and ecosystem dynamics. It includes stress effects studies, emphasizing multiple factor analyses, and utilizes a variety of plant and animal life. Other aspects deal with metabolic pathways in organisms as well as in ecosystems, population genetics, competition between species, and model building and systems analysis. In order to coordinate the various research activities of the entire group, the research is centered on a large segment of man's environment, the Altamaha River System. The terrestrial ecosystem studies are concentrated on the granite outcrops and adjacent communities at the headwaters of the river. Ionizing radiation is used, either as an ecological stress in effects studies, or as radioisotopes in tracing metabolic pathways. This is a large program, involving many more faculty and staff than listed above. Reprints of past work are available. The program is projected indefinitely, having started in 1956.

5.0263, MECHANISM OF RADIATION EFFECTS ON THE TRANSPORT AND BIOELECTRIC PROPERTIES OF RAT INTESTINE
J.R. MCKENNEY, Medical Coll. of Georgia, School of Medicine, *Augusta, Georgia* 30902 (AT-(40-1)-3882)

The objective of this research is to determine the effects of ionizing radiation responsible for the breakdown of salt, fluid and nutrient absorption. Effects of both acute radiation exposure and bile diversion are being studied. Current results indicate that after 1200 R X-radiation salt and glucose transport are transiently elevated with subsequent depression of salt transport by the third day and glucose transport by the fourth day. Initial electron microscopy indicates related effects on intracellular structure. The unidirectional flux of glucose following X-irradiation appears to be a predictable function of the difference between the unidirectional fluxes for N and Cl ions. Unidirectional electrolyte and water fluxes were coupled. Bile diversion caused a five-fold increase in the unidirectional flux of glucose. This research is being performed with isolated rat intestine and includes (1) flux measurements with radioisotopes and glucose (2) intracellular voltage measurements and (3) electron microscopy. Current objectives are to continue studies on electrolyte, water and glucose transport, bioelectric properties and architecture of the mucosa between one and four days following exposure to 1200 R X-radiation.

SUPPORTED BY U.S. Atomic Energy Commission

5.0264, STUDIES ON THE EFFECT OF NEUTRON IRRADIATION ON SEEDS
H.J. HAMANN, Gesellschaft Fuer Strahlenfor., *Hannover, Germany*

The effect of intermediate neutrons and the energy dependence of the biological action of fast neutrons on seeds. Irradiation of seeds of various water and oxygen content of Hordeum vulgare, Vicia faba minor and major, Vicia vilosa and Vicia sativa with intermediate neutrons and monoenergetic fast neutrons of 14.7 and 3.4 MeV and with 60-Co-gamma rays. Determination of germination rate, growth inhibition and chromosome aberrations in the first mitotic cycle of the root tip cells. Interpretations of the results on the basis of microdosimetry and with regard to elastic collisions. Testing of new methods of neutron spectra determination and in the intermediate range: 1) a helium-3-counter, which can be shielded by capsules of boron and lithium flouride of different thickness; and 2) a set of resonance detectors consisting of special metal oxides suspended in polyethylene foils.

Investigation of the effect of fast neutrons, thermal neutrons, and gamma rays on algae (Chlorella vulgaris and Scenedesmus obl.) grown in heavy water. The absence of hydrogen in the cells should influence the neutron action more than the gamma action in comparison to the normal algae, because hydrogen is the essential element for the energy transfer in the case of neutron irradiations.

5.0265, THE EFFECT OF GAMMA IRRADIATION ON THE LIPID METABOLISM OF RADIOSENSITIVE TISSUES
C.J. MIRAS, Athinisin Eth. Kai Kap. Panep., *Athens, Greece*

Experiments performed up to this date have shown that bone marrow cells from irradiated New Zealand rabbits show pronounced differences in their lipid metabolism as compared to sham irradiated animals. However, the lipid metabolisms of 'in vitro' irradiated bone marrow cells do not respond to ionizing radiation.

This project will be continued by investigating the changes produced by whole body irradiation of the animals on the lipid composition of the plasma membranes as well as of the cytoplasmic membranes of thymocytes and possibly of bone marrow cells. These results will be eventually compared with changes found in liver cells.

5.0267, IRRADIATION INDUCED CHANGES IN RED BLOOD CELL METABOLISM AND MEMBRANE STRUCTURE

S.R. HOLLAN, Natl. Blood Service, *Budapest, Hungary*

A detailed study of radiosensitization induced by iron and the effect of irradiation on the iron uptake and iron metabolism of erythrocytes. In addition to mature human erythrocytes, foetal type of immature erythrocytes and reticulocytes shall be studied. In the latter, the changes shall be observed that take place in iron uptake and incorporation on irradiation, parallel with the study of the changes in the haemoglobin synthesis. It shall be established to what extent the changes of the specific radioactivity of the non-haemoglobin type intracellular iron binding protein are characteristic of (1) the changes in the iron uptake, and (2) the disturbances of the haemoglobin synthesis induced by irradiation. The project will be studied by a chromatographic separation of the intracellular proteins following the uptake of 59-Fe. Based on the increase of the 42-K-outflow on irradiation, the effects of a great number of radioprotective compounds in a comparative 'in vitro' system shall be controlled. While studying the same characteristics of the antibodies of anti-D specificity, the experiences obtained in radiosterilization of erythrocyte antibodies of anti-A and anti-B specificities shall be used.

5.0269, MECHANISMS OF LOCAL CARCINOGENESIS - RADIATION, PLASTIC FILMS, AND OTHER AGENTS

A.M. BRUES, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

A most difficult problem in radiation protection is that of evaluating the carcinogenic risks of localized tissue irradiation. Dose-response relationships, relations of area irradiated to response, relative susceptibilities of tissue and cell types, and influence of other factors such as foreign-body reactions, are among the factors not well understood. Carcinogenesis by external beta-irradiation and the influence of cancer-promoting agents, by localized insoluble plutonium deposits, and by implants with and without incorporated radioactive materials, are all under investigation.

Millipore implants in subcutaneous tissues of rodents are carcinogenic when the pore size is 0.1 mu or less and ineffective with pore sizes of 0.4 mu and above. Radioactive implants of plastics are highly carcinogenic in rodents, but are ineffective in dogs for at least 5 years. When plutonium is given so as to be retained about half locally and half in the skeleton, the preponderance of tumors appears in bone.

SUPPORTED BY U.S. Atomic Energy Commission

5.0270, SOFT TISSUE RETENTION OF STRONTIUM-90

A.M. BRUES, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-eng-38)

The soft-tissue distribution of Strontium-90 is of particular interest in relation to gonadal radiation exposure. The dosage resulting from injection varies widely with age and species, depending on two factors: rapid exchange with the labile compartment of bone, and rate of excretion. Translocation of yttrium-90 resulting from Strontium-90 disintegration may result in relatively higher radiation doses to certain tissues which concentrate it. This is to be further investigated using injections of Strontium-90 from which yttrium has been separated.

Results: Integrated soft-tissue concentration curves expressed the basis of body concentration at the time of injection, vary from 2-5 hours in the young rodent to several days in adult large mammals. There is a slight redistribution of yttrium to a few tissues, notably liver.

5.0271, ANALYSIS OF PARAMETERS INFLUENCING CARCINOGENESIS

P. FAILLA, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

In considering factors involved in radiation carcinogenesis, parameters other than total dose such as energy and mode of deposition of radioactive materials, dose rate of either internal or external irradiation, and the volume and type of tissue exposed must be appraised. Other variables such as age, tissue turnover rate, latent period and their differences among species are also relevant. Available data are being analyzed from these points of view in the hopes of effecting valid interspecies extrapolations and elucidating basic mechanisms. In addition, skeletal radiographs of mice exposed to single doses of neutrons, X-rays and fractionated doses of gamma radiation are being examined to estimate bone tumor incidences.

Results: So far the percentage of bone tumors found by the above mentioned technique has been about 4% over-all with the highest percentage in the neutron-exposed group and the lowest in the mice exposed to single doses of X-ray. Some of the dose response data have been fitted by curves with equations having parameters subject to reasonable interpretation biologically.

SUPPORTED BY U.S. Atomic Energy Commission

5.0272, RADIATION RESPONSE AND RECOVERY IN SEA URCHIN GAMETES

P. FAILLA, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

Recovery from gamma ray-induced division delay in fertilized sea urchin eggs has been demonstrated by using various treatments to prolong the duration of the first division cycle - presumably affording more time for repair to take place. By using inhibitors of specific cellular processes it is possible to characterize better the nature of the radiation effect and the recovery mechanism.

Since many biological systems exhibit recovery after exposure to sparsely ionizing radiation but not after exposure to densely ionizing radiation, it was felt important to compare the recovery after sea urchin sperm has been irradiated with alpha particles from Curium144 with that observed after irradiation with gamma rays from Cesium137.

Results: Interference with aerobic metabolism or spindle formation does not block the recovery process while inhibition of protein synthesis in some cases does. It has not been possible to demonstrate any recovery at reduced temperatures. Also, the recovery evident under anoxic conditions after exposure of sperm to gamma radiation is either non-existent or of a much lower order of magnitude after exposure of sperm to alpha radiation.

5.0273, RADIATION AND ENZYMES

R.N. FEINSTEIN, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

Although the effect of ionizing radiation on many tissue enzymes has been described, there is a paucity of information regarding effects on the class of flavoprotein enzymes. This seems particularly regrettable because this is, in general, a class of enzymes producing hydrogen peroxide, which may be of importance in the radiation syndrome.

We have investigated the effects of three doses of X-radiation (5, 50, and 500 r) to the whole body on the activity of the following eight enzymes in mouse liver and kidney: D-amino acid oxidase, L-amino acid oxidase, L-alpha-hydroxy acid oxidase (short chain), L-alpha-hydroxy acid oxidase (long chain), monoamine oxidase, diamine oxidase, uricase, and xanthine oxidase. Of these 16 enzymes (eight each in liver and kidney), nine were not detectable at any time, and four were detectable but not affected in activity by irradiation.

Results: The remaining three enzymes, all of which showed increased activity after all doses of radiation, were: liver monoamine oxidase, kidney D-amino acid oxidase, and kidney L-alpha-hydroxy acid oxidase (long chain).

Because the effects were so few, so small in magnitude (although statistically significant), and relatively independent of radiation dose, this class of enzymes is considered not to be of importance or particular interest in radiation biochemistry, and the project has been terminated.

5.0274, TOXICITY OF RADIOSTRONTIUM IN DOGS

M.P. FINKEL, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

Dogs were treated with Sr89 and Sr90 under a variety of exposure conditions to determine the influence of age, duration of exposure, and level of radionuclide contamination upon the pathologic consequences. Some animals received a single injection when they were very young or full- grown; others received 257 injections during the course of one year, treatment starting at birth, during the juvenile period, or after two years of age. Another group was treated in utero by injecting radiostrontium into pregnant dogs a few days before parturition. The series includes 182 dogs: 152 beagles and 30 mongrels. Twenty-six of the 62 living dogs are control beagles. The animals receive periodic physical examinations, and roentgenograms of the entire skeleton are viewed once or twice a year. Autopsy when moribund includes histopathologic study of most organs, with special attention given to bone.

Results: Osteosarcoma has been the main cause of death. Other tumors probably attributable to radiostrontium have been myeloid leukemia, epidermoid carcinoma of the oral cavity, and tumors in the head apparently originating in the central nervous system. There has been no indication that the neonatal and juvenile dog is more sensitive than adults to either the lethal or the oncogenic effects of radiostrontium. However, the presence of a large body burden during the period of growth seriously disturbed skeletal development.

5.0275, INTERACTION OF SR90 WITH ONCOGENIC AND NON-ONCOGENIC VIRUS IN PRODUCING BONE CANCER IN MICE

M.P. FINKEL, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-eng-38)

The hypothesis that radiation induces cancer by inactivating an inhibitor of viral replication, that the virus is present in non-viral form as a necessary and normal constituent of the cell, is being tested by treating CF1 mice with both FBJ osteosarcoma virus and Sr90. FBJ virus has been given at birth and Sr90 at 28 days of age or later. Virus also has been given in immunizing doses during the month preceding injection of radiostrontium, and it has been given after Sr90. Since FBJ-induced and Sr90-induced bone cancers can be differentiated in most cases on the basis of roentgenographic and histologic appearance, it is possible to determine how combined treatment influences the response to these two oncogenic agents for mouse bone. However, in order to avoid some of the complications resulting from death due to FBJ bone cancer before the mice are old enough to be treated with Sr90, a non- sarcomatous CF1 virus, recently isolated in the Viral Carcinogenesis Branch of the National Cancer Institute will be used in some experiments. Also, prevention of Sr90 induction of bone cancer will be attempted by repeated injections of rabbit anti-FBJ serum during the latent period for Sr90 oncogenesis.

Results: FBJ virus given at birth caused an earlier than usual appearance of Sr90 bone cancer. However, if the mice were 28 days old at the time of radioisotope injection, there were fewer tumors than there were without virus pretreatment. Tumor incidence was not changed if the mice were older when Sr90 was injected. Immunization with FBJ virus had no effect on the subsequent development of Sr90 bone cancer, but when FBJ virus was given after Sr90, there were fewer FBJ tumors than there were without radiostrontium pretreatment.

5.0276, LATENT PERIOD TO THE INDUCTION OF BONE CANCER BY SR90 IN MICE

M.P. FINKEL, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-eng-38)

It has been recently observed that some CF1 mice treated with 1.0 mu Ci Sr90/gm died with bone cancer sooner than usual. The only difference in customary procedure was that serum was collected from these animals on several occasions by bleeding from the orbital sinus. This suggests that the latent period to bone cancer induction after treatment with Sr90 is shortened when the bone marrow is in an unusually active proliferative state. To test this observation, 30 mice were given 1.0 mu Ci Sr90/gm; 15 received no further treatment, and 15 were bled from the orbital sinus 5 times during the next 18 days. Skeletal damage and neoplastic change are being studied by weekly roentgenographic examination. This kind of approach to latent period problems might be fruitful; information in this area has been very difficult to obtain because it requires an understanding of the processes going on during the period between administration of a radionuclide and first appearance of pathologic change. The reason for concern about latent period is the necessity to know the precise time when irreversible neoplastic change occurs if the absorbed dose from a bone-seeking radionuclide responsible for inducing bone cancer is to be estimated.

Results: The first osteosarcoma was detected roentgenographically in a mouse that had been bled 99 days after Sr90 was injected, and at 114 days there were 2 more cases in this group. The first bone cancer in the non-bled mice was detected at 130 days. This kind of difference has persisted, and at the last examination 193 days after radioisotope administration, there were 25 osteosarcomas in the bled mice and 17 in those not bled.

5.0277, CORRELATIVE ACTION OF THE GAMMA-IRRADIATED LEAF ON ROOT INITIATION IN COLEUS

S.A. GORDON, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

It has been shown that auxin, carbohydrate, and nitrogenous factors are required for the de novo initiation of roots on cuttings. The leaf governs the formation of roots by supplying the limiting factors. The present study was undertaken to determine whether or not petiolar root formation is affected by exposure of only the blade to ionizing radiation. If so, the above factors will be investigated in search for loci of in vivo radiosensitivity. Coleus leaves are exposed to Co 60 gamma rays, the petiole base being shielded by lead.

Results: Irradiation of the leaf blade, using dosages that suppress the initiation of roots on the petiole by 50%, had no immediate effect on petiolar levels of carbohydrate or nitrogen. However, the concentration of petiolar RNA began to drop several hours after irradiation. The radiation-induced loss of RNA is apparently not a consequence of an impaired biogenesis, since incorporation rates of C14- labeled uracil into RNA were unaffected. The effect of irradiating the blade on the activity of petiolar RNAase was therefore determined. Gamma-irradiation of the blade causes an enhancement of observed and specific petiolar RNAase activity at 14, 25 and 40 hours after exposure. Hence the loss of RNA that occurs in the petiole base after irradiation of the blade can be attributed to a hormonal activation of RNAase activity. That this hormone is auxin can be inferred from the finding that both the impairment of root initiation and the fall in RNA induced by irradiation can be reversed by supplying auxin. If so, the action of auxin is not simple and direct: immersion of the petiole in auxin solution enhances gross RNAase activity in the petiole. Tentatively, we postulate that the auxin-induced rise in RNA in turn promotes an RNase activity that is compartmentalized with respect to the RNA involved in the formation of root initials.

5.0278, NEUTRON AND GAMMA RAY TOXICITY STUDIES EMPLOYING THE JANUS BIOLOGY REACTOR COMPLEX

D. GRAHN, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

The need for information concerning the potential hazards to man of long-term low-level exposure to fission neutron and gamma radiation continues to be compelling. These studies will be an integrated experimental approach to this general problem and will have a primary objective of defining basic cellular and tissue mechanisms of chronic radiation injury. These data, when integrated with adequate epidemiologic data on death rate from specific neoplastic and degenerative diseases, short-term and long-term recovery rate data for critical proliferating cell systems, and data from selected species and environmental comparisons, should provide the basis for predictions of the consequences of most occupational or accidental exposures to neutron and gamma radiation. Although the main effort will be on the late effects of radiation, some acute toxicity and lethality studies will be required for baseline purposes. In the course of these studies, information on the normal aging processes of rodent populations will accrue as necessary information for the proper evaluation of radiation induced changes and age: radiation interactions. Initial studies will evaluate fractionated, terminated exposures and certain dose-rate variables on the life expectancy, leukemia death rates, hematopoietic and intestinal system cell kinetics. Extensive duration-of-life irradiation series and regimes involving exposures terminated in mid life and beyond will be established on the basis of initial study results.

5.0279, CHANGE IN RADIOSENSITIVITY OF INTESTINAL CRYPTS FROM GROUND SQUIRRELS DURING THE FIRST 48 HOURS AFTER AROUSAL FROM HIBERNATION

B.N. JAROSLOW, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

Although initial energy-transfer reactions following irradiation are probably the same over the temperature range of hibernation (ca 5 to 23 degrees C) as they are for mammalian tissue cultures grown over a temperature from 25 to 37 degrees C, the biochemical events resulting from energy transfer after irradiation are temperature-dependent. Thus, the development of pathology (biochemical events) is retarded in hibernating ground squirrels given lethal doses of radiation and they do not die as long as they hibernate. Following arousal pathology rapidly develops and they die showing that the original radiation injury (initial energy-transfer) had occurred. We observed that mortality of irradiated ground squirrels after arousal from hibernation was less than in non-hibernating irradiated controls. The investigation was aimed at determining the dominant factors that contribute to the decreased radiation injury associated with post-irradiation hibernation. In studies of the effects of hibernation on radiosensitivity and on recovery from radiation injury, we observed that mortality was the same for ground squirrels irradiated while awake or in hibernation. If they were permitted to hibernate after irradiation, a net increase in the rate of recovery was observed as demonstrated by a doubling of the number of survivors. To refine the sensitivity of the system ground squirrels were irradiated with CO60 gamma rays at different times after arousal from hibernation and their intestinal crypts were examined to determine survival. The intestinal crypts provide a uniform population of cells that can be readily scored to assess radiation injury. Results: Hibernating ground squirrels were removed from the cold room and were irradiated with CO60 gamma rays at 15 min, 1 hr, 3 hr, 7 hr, 12 hr, 24 hr, and 48 hr after initiation of arousal. Pieces of ileum were sectioned and the number of intestinal crypts with dividing cells from animals irradiated during the first hour after arousal from hibernation, as compared to non-hibernating irradiated controls, was approximately 3:1 after 1500 R, 6:1 after 1600 R, 12:1 after 1700 R, and 35:1 after 1800 R. As the interval between arousal and time of irradiation increased the response reached control values.

5.0280, TOXICITY OF TRITIUM-LABELED COMPOUNDS

W.E. KISIELESKI, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-eng-38)

Continued and increasing use of tritiated nucleic acid precursors requires investigation of the radiological effect of tritium incorporated preferentially into the nuclei of cells including possible radiation effects that introduce experimental error in studies of cell kinetics, and the possibility that tritiated nucleic acid precursors may constitute a serious hazard to the health of man. The latter concern is relevant to the production of tritium and its release into the environment of nuclear power plants and fuel reprocessing facilities.

To properly evaluate the possible radiological hazard of tritium- labeled compounds (e.g., thymidine, uridine, and leucine), factors that control uptake, distribution, excretion, and reutilization must be fully understood. This investigation attempts to obtain quantitative data in order to elucidate these various factors. Liquid scintillation counting in combination with combustion techniques are used to detect and measure low-energy beta emission of tritium. Cerenkov radiation counting of the more energetic beta-emitter are evaluated and studied to give a new and greater dimension in liquid scintillation measurement.

Results: Our experiments indicate that the toxicity of tritium bound to nucleic acid precursors varies with the site of incorporation, the rate of renewal of the labeled macromolecule, and the extent of interconversion and reutilization of catabolites. In comparing DNA, RNA, and protein synthesis in different tissues, the uptake of tritiated precursors and the intensity of the autoradiographic label are differently affected in different organs by the route of administration as well as the specific activity (Ci/mM). For tritiated thymidine the degree of early somatic and genetic effect from intranuclear tritium is that anticipated on the basis of calculated absorbed dose to the cell nucleus.

5.0281, THERAPY OF POISONING BY RADIOACTIVE AND NONRADIOACTIVE METALS

A. LINDENBAUM, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

The overall purpose of this project is the development and evaluation of new concepts and techniques for the therapy of poisoning by radioactive and nonradioactive metals that deposit primarily in the bone and liver. In anticipation of problems of human decontamination arising from the increasing usage of highly radiotoxic actinide elements, current work is being centered on plutonium and americium. Increasing emphasis is being placed on the relationship between the physical-chemical properties of compounds of these nuclides and their physiological behavior, both for applications to therapy and for an improved understanding of the general behavior of macromolecules and colloids in tissues. The mouse is the principal species used, but comparative studies with other species (e.g., rat, rabbit, and dog) are included. Present efforts toward therapeutic removal involve use of the chelating agent DTPA (diethylenetriaminepentaacetic acid), either alone or in combination with other types of therapeutic agents (e.g., the yeast polysaccharide glucan, which increases removal of intracellular plutonium from liver). Another approach aims at alteration of normal physiological processes in bone and liver to liberate the radioelement. Among techniques used are radiochemical assays, electron microscopy, autoradiography, and ultrafiltration. Toxic and therapeutic effects in animals are measured by changes in median lethal dose, tumor induction, histopathology, and longevity. Results: In mice, studies of the lifetime influence of physical-chemical properties of plutonium have thus far shown that after injection of highly polymeric plutonium: 1) about 65% of the skeletal burden is in the marrow (compared to under 5% after monomeric plutonium); 2) deaths from aemia may follow (e.g., all mice receiving 7.8 mu Ci/kg die within 4-9 months); 3) much of the plutonium leaving the liver is translocated to bone surfaces shown earlier to be at high car-

cinogenic risk. In liver cells, both monomeric and polymeric plutonium were found associated with lysosomes; but most of the polymeric plutonium was non-lysosomal, possibly bound to cell membranes.

5.0282, METABOLISM AND DISTRIBUTION OF BONE-SEEKING NUCLIDES BY MAN

H.F. LUCAS, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-38)

The radiation dose to man from internal deposits of alpha-emitting nuclides is highly dependent on the distribution within the body and the rate of change of body burden with time after exposure. The metabolism of radium 30-40 years after exposure is being evaluated. For living humans the body burden is determined by radon breath and gamma-ray spectroscopy. The rate of change of body burden is determined by the radiochemical assay of blood, urine and feces. The macroscopic distribution of Ra226, Po210 and Pb210 is being determined in 100 specimens from a recently deceased radium dial painter skeleton. In addition, the microscopic distribution is being evaluated by the autoradiographic-microradiographic technique. The metabolic and distribution parameters will be used to test theoretical predictions of the long-term behavior of these and other bone-seeking nuclides by man. Results: The rate of clearance of Pb210 and Po210 from the blood of radium patients was found to average 0.09 and 1.6 liters per day, respectively. From biopsy specimens, the Pb210 to Ra226 ratio in bone was 0.30 which is in good agreement with that expected from radon retention studies.

5.0283, MECHANISMS AND MODELS OF SKELETAL METABOLISM--THEORETICAL

J.H. MARSHALL, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

Purpose: To provide quantitative descriptions of the processes of uptake and release of bone-seeking radioisotopes. These descriptions are directed towards 1) elucidation of the mechanisms of skeletal metabolism, and 2) predictions of the ratios of toxicity of bone-seeking radioisotopes in man and in dog.

Summary of Proposed Work: A new model of bone turnover is being developed which will extend the power function model to describe the microscopic processes of alkaline earth uptake and retention. Local retention functions have been constructed for bone surface, bone volume, cortical bone, trabecular bone, regions of new bone formation, regions of existing bone (the diffuse component), and soft tissue. The effects of resorption and of diminution are explicitly described for each bone component. Available microscopic data, while not plentiful, are sufficient to place realistic constraints upon the model for both dog and man.

The model will be used to calculate dose to endosteal bone surface for ICRP.

Results: A comprehensive analysis has just been published. 'Measurements and Models of Skeletal Metabolism' in Mineral Metabolism, Volume III, edited by C. L. Comar and F. Bronner, Academic Press (1969). This chapter summarizes the work of the bone group 1955-1969, and places the concepts of bone turnover and alkaline earth transfer on a firm operational basis.

The prediction of a final exponential in the retention of radium in man has been confirmed using the data for George Harrison (Radiation Research 39, 445, 1969).

5.0284, METABOLISM AND TOXICITY OF FISSION PRODUCTS IN DOGS

W.P. NORRIS, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

The ultimate aim of this work is to establish the effects of raw fission-product mixtures in biological systems relatable to man. The complexity of fission product mixtures is such that the problem is approached by selecting representative fission products that have highly different distribution patterns in the body. These are Ce144, Cs137, and I131. In addition, a Co60 gamma-ray source is used to deliver wholebody radiation continuously in order to simulate certain aspects of radiation from internally deposited radionuclides.

Pure-bred beagle dogs are treated with these agents and attempts are made to define the mechanisms and causes of both acute and chronic deaths.

Results: At dose rates to bone marrow of 8 rad/day and above the causes of death are directly relatable to marrow damage. At 28 rad/day death is caused by septicemia secondary to leukopenia. At 14 rad/day the primary cause changes to anemia, while at 8 rad/day leukemia is frequently seen. Low platelet counts do not appear to be a prime factor at any of these dose rates.

The reduction in the hyperplastic response of the thyroid gland to low dietary iodine levels provided an excellent method for evaluating injury to the thyroid at radiation doses below 2000 rad.

5.0285, MEASUREMENTS OF RADIOACTIVITY IN VIVO AND APPLICATIONS IN HUMAN RADIOBIOLOGY

J. RUNDO, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

Three shielded rooms are being constructed in an underground laboratory supplied with radon-free air, in order to make measurements of radioactivity in man at the lowest possible level. Subjects studied will be persons who worked with radium many years ago, as well as those who may become contaminated internally as a result of accidents. Short- and long-term retention parameters will be determined by making repeated measurements over such periods of time as may be necessary. Particular attention will be paid to the determination of distribution within the body as well as of total body content. A special problem is posed by those radionuclides such as Pu-239 which only emit low energy radiation, the attenuation of which by overlying body tissues is severe and variable. Large area low background pr.swich detectors and proportional counters will be used for the measurements, and calibration will be studied with the help of volunteers who inhale short-lived 'mock plutonium.'

5.0286, THEORY OF AGING, MORTALITY AND RADIATION INJURY

G.A. SACHER, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

Purpose is to develop a mathematical theory of radiation injury, and a theory of aging and death, that will make possible the quantitative estimation of morbid and lethal effects of ionizing radiations in various mammalian species, especially for the conditions of long-term exposure. This is essential for the development of a valid predictive model for estimating late radiation effects in man (see SIE 'Acute and Chronic Radiation Effects'). The overall problem is extremely complex, and the attack is therefore by stages, as follows: 1) identify all the significant factors; 2) develop adequate theoretical models for the factors separately; and 3) synthesize progressively more complete models of the whole system. Work is now mostly in stage (2). The kinetics of injury and repair in the blood-forming systems is moving to a third cycle of computer simulation. The theory of the stochastic relation of disease incidence and death to tissue injury has been developed and an advanced computer simulation is under development. Theory of the kinetics of radiation damage to chromosomes and cell division is under development.

Results: The statistical theory of mortality explains how the sigmoid life tables of mammalian populations can arise from steadily accumulating molecular aging injury, and correctly predicts the kind of perturbation of the life table produced by radiation exposure. The mathematical model of dose rate dependence and physiological recovery, now under development, can already account for much of the available data on species differences in chronic sensitivity.

5. RADIATION

SUPPORTED BY U.S. Atomic Energy Commission

5.0287, ACUTE AND CHRONIC RADIATION EFFECTS IN MAMMALS

G.A. SACHER, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

Purpose is to develop a quantitative model of morbidity, mortality and life shortening in mammals that will be valid between species, and capable of estimating radiation effects in human population. As radiation levels in the environment increase, the need for correct estimates of effects in man becomes greater. Since the available human data is limited, any considerable increase of knowledge must come from animal research. Procedure is to measure the effects of a standard set of radiation exposure conditions on blood formation, disease incidence and length of life of a diverse group of mammalian species, and to use the data as the basis for the development of a quantitative mechanistic model of life shortening in mammals. In the current stage the test species are small myomorph rodents of the genera 'Mus', Praomys', 'Peromyscus', 'Sigmodon oryzomys', and 'Tamias'. Subsequent stages will broaden the group to include small marsupials, insectivores and primates. The radiation sources used are gamma rays presently and fast neutrons in the near future.

Results: The group of rodents listed above has been shown to have a 5-fold range of sensitivity to low-level chronic exposure, whereas the conventional 50LD estimate of sensitivity shows them varying by only a factor of 2. Experimental evidence has been produced showing that the life-shortening effect varies as the first or the second power of the dose rate, in different dose rate ranges (see SIE 'Theory of Aging, Mortality and Radiation Injury').

5.0288, THE EFFECT OF RADIUM IN HUMAN BONE

D.J. SIMMONS, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-38)

Human skeletal material burdened with radium (Ra226, Ra228) will be studied at the microscopic-microradiographic level to quantitate the tissue pathology. Autoradiography will be used to measure the microscopic alpha dose to bone. Additional human skeletal materials showing a variety of non-irradiation pathologies will comprise a control series.

Results: We have developed an autoradiographic method which involves coating tissue sections with solutions of cellulose nitrate. These detector films which are selectively sensitive to alpha particles (4.5-5 MeV) (and insensitive to beta rays) can provide for greater resolution than nuclear emulsions. Alphagraphs of this type can be quantitated by track-counting techniques.

5.0289, RADIOSENSITIVITY OF MAMMALIAN CELLS IN TISSUE CULTURES

W.K. SINCLAIR, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

A major goal of this study is to investigate the variation in lethal radiation response during the mammalian cell generation cycle and its relation to biochemical events, particularly controlling events, occurring in that cycle. Radiation resistance is in part controlled by DNA synthesis and also as recent results have shown (see below) sulfhydryl groups are implicated. The exact involvement of the latter needs clarification. Using a synchronized system of Chinese hamster lung cells in culture we intend to determine the relative concentrations of free and bound sulfhydryl at different stages of the cell cycle and to further expand recent experiments on sulfhydryl binding agents. The latter show that N-ethylmaleimide (NEM) sensitizes cells most when they are most resistant, i.e. at the latter part of the S period. Future experiments will examine the extent to which NEM and MEA can neutralize each other and the effects of other sensitizers on cells at different stages of the cell cycle. These and other pertinent questions should help to establish the role of sulfhydryls in controlling the cyclic radiation response on mammalian cells.

Results: Mammalian cells in culture show a fluctuation in lethal response to X-rays during the cell generation cycle, being resistant in late S, sensitive in Gsub2 and mitosis, and intermediate and sometimes varying in sensitivity during Gsub1. This is related in part to DNA synthesis during the S period. Results with sulfhydryl protectors such as cysteamine indicate that sulfhydryls are also involved in controlling the radiation response. Further work, directly on sulfhydryl content as a function of time in the cell cycle and on the effects of sulfhydryl binding agents, tends to confirm this.

5.0290, CORRELATED STATISTICAL AND CYTOPHYSIOLOGICAL STUDIES OF THE RADIATION RESPONSE IN HIGHER VERTEBRATES

S.P. STEARNER, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

Kinetic models of radiation injury and repair, formulated from mortality data from birds and mammals, emphasize dependence of the injury on physical factors of the irradiation (e.g. dose, time, exposure pattern). Models are considered in relation to selected injury reactions of acute and chronic responses that are studied in detail at functional and structural levels. Objectives of statistical descriptions are to identify and separate mechanisms involved in acute radiation death (within 30 days) in higher vertebrates and to describe time-dose relations of processes of injury accumulation and repair after protracted, split, or fractionated exposures. Total exposure periods or intervals between exposure fractions do not exceed 24 hrs. In studies of mechanisms of radiation injury, current emphasis is on early vascular damage. Circulatory collapse is characteristic of the initial syndrome (death within 1-2 days) in the chicken. This effect is subject to rapid repair or reversal and is exposure-time dependent. A similar early vascular damage is observed in mammals but does not terminate in general circulatory stasis. Investigation of early vascular damage includes (1) effects on dynamics of the microcirculation (in vivo cinemicrographic study) and (2) ultrastructural study of blood vessels, with special attention to behavior of tracer particles and to hydrolytic enzyme localizations. A small group of chickens is being maintained for duration of life, for investigation of dose-protraction effects on later mortality.

Results: In the chicken and mouse, acute lethality from a single dose of Co-60 gamma rays is reduced as dose protraction is increased. For early mortality (less than 2 days after exposure) in the chicken, split exposures revealed that a resistance (increased tolerance) can be induced by an initial (conditioning) exposure and a relatively refractory state is produced. Stasis and degeneration of the microcirulation, after either protracted or split exposures, can be correlated with mortality. Ultrastructural studies suggest endothelial degeneration results from direct injury. Long-term observations indicate doses protracted over 24 hrs are less effective than shorter exposures (60 min) in reducing survival time.

5.0292, ULTRASTRUCTURE CHANGES ASSOCIATED WITH CELL DIFFERENTIATION IN NORMAL AND IRRADIATED ORGANISMS

T.N. TAHMISIAN, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

Cells most vulnerable to radiation damage have become differentiated from undifferentiated stem cells. These include sarcoblasts which differentiate into muscle, germ stem cells that differentiate into spermatozoa, or undifferentiated bone marrow cells that become granulocytes and red blood cells. This differentiation typically follows changes in subcellular structures and the production of other membrane fibers and organelles. Irradiation inhibits some of these essential changes and enhances others, i.e., supernumerary tails in sperm and the over production of plasma cells by bone marrow. The study of ultrastructure in both normal and irradiated material provides evidence of the cause for deviations from normal development. To gain this information cytochemical, cytological, and physiological methods are used in combination with biochemistry, light, and phase microscopy and high resolution electron microscopy. Insect testis, embryos and muscle, and canine bone marrow are used in this study of irradiation injury. Chemicals and antibiotics that are specific intracellular inhibitors are used to compare chemically induced deviations with those produced by ionizing radiation, to establish specific radiation effects.

Results: Paracrystallinity is typically produced during differentiation, i.e., chromatic sperm acrosome and mitochondria. Irradiation produces the same condition in nuclei, mitochondria and myelination of the cytoplasm. This paracrystalline condition has been compared with crystalline proteins and enzymes by high resolution electron miscroscopy.

5.0294, PREPARATION AND PROPERTIES OF SUBCELLULAR FRACTIONS

J.F. THOMSON, Argonne National Laboratory, *Argonne, Illinois* 60439 (2-31-109-ENG-38)

Isolation of subcellular fractions is an important analytical tool for the study of cell physiology and biochemistry, including the study of the fine structure of cell organelles. Our study is directed toward the development and application of methods of density-gradient centrifugation that relate the concentration of the cellular components to the size of the particulates with which they are associated, rather than to morphologic labels of doubtful meaning.

The procedures already developed in this laboratory have been valuable in the comparison of tissues from normal animals and those treated in various ways, including exposure to X-rays. They have also been sucessfully adapted as preparative techniques. Sucrose gradients are prepared by use of various gradient-forming devices. After a tissue homogenate is layered over this gradient and the tube containing it is centrifuged, successive layers are collected and are analyzed for a number of constituents. Since the average particle size in each layer can be predicted from an equation derived from Stokes' Law, the relationship between concentration and particle size can be estimated. Currently, we are carrying out tissue fractionations in a zonal centrifuge, which provides much finer resolution of subcellular particles than is possible by other procedures that involve centrifugation.

Results to date: Mitochondria isolated from mice previously injected with various radioprotective thiols show an altered sedimentability. Treatment with cysteine, mercaptoethylamine, or aminoethylthiophosphate results in significantly decreased sedimentability, whereas AET S-(2-aminoethyl) isothiouronium bromide hydrobromidel) has the opposite effect. An N-substituted compound, N- (aminopropyl)-aminoethylthiophosphate affects sedimentability very little. These in vivo effects do not correlate well with results of in vivo experiments on mitochondrial swelling.

5.0295, KINETIC MODELS OF PHOTOREACTIVATION IN BACTERIA

S.A. TYLER, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

UV irradiated bacteria of many strains are reactivated by visible light and the degree of reactivation is dependent on its intensity and duration. It was first postulated that visible light simply reduced the effectiveness of the irradiation. Inherent in this postulation is the assumption that the effects of UV are not primary and can be nullified before the initial injury (lesion), leading to inactivation of the cell, is established. This 'dose-reduction hypothesis' is too restrictive to account for the observed survival patterns of many organisms after photo reactivation. In this study, we attempt to construct a phenomenological model of greater generality. The underlying assumptions upon which our approach is based are: (1) among the lesions produced by UV irradiation there are specific events that inactivate the cell, (2) registration of a single event in the cell is sufficient to inactivate the cell; (3) events are reversed sequentially or randomly by exposure to visible light; (4) the cell is reactivated when, and only when, all events sustained are reversed. Four models were constructed that differ either in the postulated distribution (Poisson or Binomial) of UV events in the cell, or in the postulated method by which reversal takes place (Sequential or Random). Appropriate survival data using cells of 'E. coli', strains WP2-hcr, AB2480 and AB1886 in stationary phase, were supplied by Dr. D.J.G. Davies of Bath University of Technology, Bath, England.

Results: Analysis of data under the postulated Binomial-Sequential model indicates that a maximum of five lethal and photo repairable events are sustained by the cells from UV irradiation.

5.0296, PHOTOINACTIVATION AND CELLULAR REPAIR

R.B. WEBB, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

Harmful effects of far ultraviolet (200-300nm), near ultraviolet (300-390 nm), and visible light (390-750 nm) on cells are investigated with the purpose of identifying the molecular mechanisms involved. Athough there are many beneifical effects of sunlight, many of the photochemical reactions that occur in biological systems are deleterious. Sensitization to near ultraviolet and visible light by exogenous chromophores, such as acridine dyes, and by endogenous chromophores, to be identified, is being studied in various microorganisms. The identity of the lesions produced, the identity of the chromophores involved, the role of oxygen, and the roles of various kinds of cellular repair are being investigated. Enzymatic photoreactivation is studied to aid in the identification of the lesions produced. The contrasting effects of acridine dyes in protecting cells against lethal and mutagenic effect of far ultraviolet radiation is also being studied.

Dose-response curves are routinely obtained with the ability of the cell to produce a visible colony as the biological end-point. Numerous radiation sources with monochromators and interference filters are employed.

Results: Extensive data on the inactivation of 'Escherichia coli' K 12 AB 2480, 'E. coli' WP2, and 'E. coli' WP2hcr by radiation from 254 nm to 750 nm implicates both excision repair and post-replication repair at wavelengths up to 500 nm. For the first time enzymatic photoreactivation (ratio, 4:1) has been demonstrated in 'E. coli' K 12 AB 2480 after inactivation by 365 nm radiation. Inactivation by 365 nm radiation is oxygen dependent in contrast to the oxygen independence of 254 nm inactivation. The photoreversal of 365 nm damage implicates pyrimidine dimers in DNA as the major lethal lesion produced by this radiation.

5.0297, PHOTODYNAMIC MUTAGENESIS

R.B. WEBB, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

Mutagenic effects of a broad spectrum of radiations are studied in continuous cultures of bacteria with the purpose of detecting initial events that lead to mutational lesions. Continuous culture techniques permit the study of mutation induction at very low (chronic) levels of the mutagen in the absence of detectable lethality. There is an ongoing program for the improvement of apparatus for maintaining continuous cultures. A photocell- controlled continuous culture device (Nephelostat) has been built.

Acridine sensitized mutagenesis is studied to relate molecular structure, physical properties, molecular affinities, and binding characteristics (intercalation?) to the mutation process. The mutagenicity of near ultraviolet (320-390 nm) and visible light (390-750 nm) is being studied in the absence of added sensitizers. The naturally occurring chromophores for this oxygen-dependent mutagenicity are of special interest because of their likely association with DNA in normal cell processes. Far ultraviolet (200-300 nm) and chemical mutagenesis are studied for the purpose of comparison.

These studies employ continuous cultures of both the chemostat and the Nepholostat type. A variety of 'Escherichia coli' strains are used. Mutations to resistance to the bacteriophages T5 and T6, resistance to streptomycin, and reversion to tryptophane independence are studied.

Results. An action spectrum for the induction of phage T5 resistance in chemostat cultures of 'E. coli' revealed an effective band between 330 nm and 500 nm. A high level of visible-light mutagenesis in 'E. coli' B/r in the absence of added tryptophane ruled out this amino acid in these oxygen- dependent processes. Results with chemostat cultures of 'E. coli' B/r/1,trp suggest that mutagenic processes affecting phage T5 resistance and streptomycin resistance are different at 254 nm, 330 nm, and at 400-750 nm.

5.0298, PULSE RADIOLYSIS IN RADIATION BIOLOGY

J. OVADIA, Michael Reese Hosp. & Med. Ctr., *Chicago, Illinois* 60616

The initial steps in radiation inactivation of aqueous enzymes such as lysozyme and trypsin are being investigated with pulse radiolysis, with current emphasis on the basic mechanisms of chemical protection. The work involves the spectral identification of intermediates produced by radical attack, measurements of rate constants and kinetics, and parallel enzymatic activity determinations. The extension to zymogen enzyme systems is planned, to clarify the effect of the primary chemical lesions on the enzymatic functions of the protein. In addition, the current study of chemiluminescent reactions between solvated electrons and triplet dye states is being continued. Evidence is accumulating that the primary step leading to additional electronic excitation of the dye involves the triplet excimer (triplet-dye complex molecule) which has broader implications for dye-sensitized reactions than the aqueous eosin system in which the effect has been first observed.

5.0299, HUMAN-PRIMATE COMPARATIVE EYE STUDY FOR LASER SAFETY CRITERIA

P.S. COOGAN, Presbyterian Saint Lukes Hosp., *Chicago, Illinois* 60612 (F41609-71-C-0006)

Technical Objective: The objective of this study is to acquire sufficient comparative human/primate retinal data to establish human laser permissible exposure criteria for Air Force operational laser systems. Presently all threshold injury data are acquired from rhesus monkeys and although their eyes are similar to man there are differences in size, retinal ultrastructure, pigment density and distribution. This study will quantify comparative human/primate thicknesses of retinal layers and retinal-choroidal pigment distributions and make possible valid extrapolations from animal data to man.

SUPPORTED BY U.S. Dept. of Defense - Air Force

5.0300, EFFECTS OF RADIATION AND DRUGS ON HAIR AND HAIR GROWTH

F.D. MALKINSON, Presbyterian Saint Lukes Hosp., *Chicago, Illinois* 60612

Continuing investigations of the effects of high dose radiation on telogen mouse hairs revealed that 15 months after radiation cell cycle division times were equal in irradiated and control sites. The reduced mitotic index in treatment sites (0.68%) compared to control areas (1.51%), however, indicated that persistent post-irradiation reductions in hair lengths reflected irreversible reductions in matrix stem cell populations.

Studies of alopecia after irradiation of anagen hairs revealed that despite immediate total loss within 5 days after doses of 1250-2000 rads, 73-88% of follicles showed hair regrowth 7-8 months later. Hair irradiated in telogen showed delayed loss 6 to 9 weeks post- radiation. Four to five-fold greater doses of radiation were required to produce threshold alopecia in non-proliferative hair cell populations (telogen) than in proliferative (anagen) matrix cells. Studies of immediate post- radiation alopecia after electron beam irradiation (5 MEV) yielded a 'hair survival curve' essentially identical to that obtained with X-ray irradiation (45 Kv).

Cell kinetics studies of anagen matrices in mice given tritiated thymidine revealed that the repeated trauma of 'double plucking' produced marked reductions in labeled cells and total mitoses as compared to singly plucked animals. Reductions in the proliferative cell pool after double plucking were also reflected in lowered levels of radioactivity following combustion and assay of groups of follicles at multiple intervals during the anagen phase of the cycle.

5.0301, CELLULAR EFFECTS OF RADIATION AND CHEMOTHERAPY

T.K. DASGUPTA, U.S. Veterans Administration, West Side Hospital, *Chicago, Illinois* 60612

Walker-256 carcinoma was transplanted subcutaneously in the dorsum of male Sprague-Dawley rats weighing 100 to 120 gm. The tumors were allowed to grow to 1 cm in diameter. The animals were divided into experimental and control groups. The tumors in the experimental animals were irradiated, the dose ranging from 50 to 2000 rads. Specimens were dissected from the irradiated tumors at intervals of 1, 2, 4, 12, 24 and 48 hours, and one week and two weeks after irradiation, and from the control animals at the same intervals. Light microscopy showed no cytoplasmic changes in the irradiated group when the dose was less than 500 rads. With 1000 and 2000-rad doses the nuclear profile changed and cytoplasmic basophilia was diminished. Enzyme histochemical stuies showed diminution of succinic dehydrogenase and coenzyme I and II as the dose was increased to 2000 rads, starting 24 hours after irradiation, with marked diminution on the seventh day. The hydrolytic enzyme activities were not altered with a dose up to 1000 rads. With a 2000 rad dose, diminution of acid phosphatase activity was seen one week after irradiation. Reaction for lipases was weaker in tumors ir-

radiated with 1000 rads or more. The cytoplasm of the tumor cells in the irradiated group showed diminution in the mitochondrial and microsomal population, most marked when the dosage was increased to 2000 rads, and one week after irradiation. On the basis of our results it can be confirmed that radiosensitivity of a malignant cell in an experimental system is largely dependent on the cytoplasmic organelles.

5.0302, ANALYSIS OF THE MORBIDITY AND MORTALITY OF CHILDREN IRRADIATED IN FETAL LIFE
M.L. GRIEM, Univ. of Chicago, School of Medicine, *Chicago, Illinois* 60637 (AT(11-1)-69)

This project is an aalysis by computer techniques of the 1st and 2nd follow-up data of 1,008 primiparas who were irradiated in utero in 1948. Control data are from unirradiated populations in 1947 and 1949. Since these subjects are now approaching child-bearing age, it has been suggested that a follow-up of the progeny of the irradiated population may also be of value in estimating radiation injury. The feasibility of such a follow-up is to be examined.

Results: The first follow-up of studies of this population (1966) indicates an increase in the number of hemangiomas (a benign tumor). Congenital malformations, eye diseases and malignant neoplasms were sought for, but there was no increased incidence in either the first (1966) or second (1969) follow-up.

5.0303, THE LATE EFFECTS AND METABOLISM OF THE BONE SEEKING RADIOELEMENTS
R.J. HASTERLIK, Univ. of Chicago, School of Medicine, *Chicago, Illinois* 60637 (AT(11-1)69)

Radiography of the radium-bearing patients who have formed the basis of these studies will be continued at selected intervals. We shall continue with our evaluation of the relationship of the present body burden, peak burden and cumulative radiation dose to the induction of osteosarcomata, tumors of the sinuses and mastoids and central nervous system. Experimental studies on mice will attempt to elucidate whether there is selective concentration of radon in the lipid rich supporting cells of the central nervous system.

A study of the alteration of micro-bone structure as revealed by scanning electron microscopic techniques will be carried out.

An apparent significant increase in tumors of the central nervous system in radium-bearing patients was demonstrated during the past fiscal years. All data on our patients has been reduced to a standard format and stored on computer tape, and a 600-page 'data book' has been jointly published by Argonne Cancer Research Hospital and Argonne National Laboratory. We expect to complete a monograph on the radium studies in 1970.

5.0304, THE MECHANISM OF THE CELL MEDIATED IMMUNE RESPONSE
R.D. PETERSON, Univ. of Chicago, School of Medicine, *Chicago, Illinois* 60637

The object of the propose research is to extend a preexisting line of investigation directed at understanding the mechanism of the cell mediated immune response. The line is the experimental model, previously developed by this investigator and his colleagues, that makes it possible to obtain a chicken capable of manifesting cellular immunity but incapable of producing serum antibodies. Bursectomized, irradiated chickens, after recovery from irradiation, lack the population of lymphocytes that synthesize serum antibodies but they regenerate those lymphocytes responsible for cellular immunity. The aim of the proposed study will be to explore this model at the cellular level because lymphocytes from such chickens may afford the unique opportunity of studying cellular immunity in a population of cells unable to synthesize serum antibodies. Sensitized lymphocytes from such chickens will be studied in vitro for clues to the mechanism responsible for their capacity to recognize and interact with antigens. An attempt will be made to determine which, if any, of four feasible possibilities is the basis of cellular immunity. These are 1) secretion of small amounts of antibody, 2) production of cell-bound antibody, 3) presence of a non-immunoglobulin material on the cell surface capable of relating specifically to an antigen, and 4) an unknown intrinsic antigen-induced alteration of the cell urelated to cell surface change.

5.0305, IDL PHYSICS, GENERAL
R.L. PLATZMAN, Univ. of Chicago, Graduate School, *Chicago Illinois* 60637

Technical Objective: This theoretical research is directed principally toward improved understanding of the early events taking place in the interaction of ionizing radiations and matter. These events are equally crucial for the physical, chemical, and biological action of the radiations. Subjects under study include: (a) Degradation of high-energy radiation; the charged-particle spectra effective in radiation action are being investigated, together with the role of such 'degradation spectra' in establishing the qualitative and quantitative character of radiation effects. (b) Detailed characterization of initial (primary) products in gases; the first state here is attainment of the complete oscillator-strength distribution of a molecule. From this distribution, inelastic scattering cross-sections can be obtained, and from these, together with the degradation spectra, absolute yields of primary products can be calculated. (c) Characterization of initial products in condensed media. (d) Immediate behavior of primary products; emphasis here is accorded the decomposition of superexcited states.

5.0306, HISTOPATHOLOGICAL CHANGES IN LABORATORY ANIMALS EXPOSED TO PROTRACTED LOW-LEVEL TOTAL-BODY NEUTRONS AND GAMMA RAYS
J.H. RUST, Univ. of Chicago, School of Medicine, *Chicago, Illinois* 60637 (AT(11-1)1487)

A study of the histological changes in small laboratory animals subjected to low levels of protracted total-body irradiation with fast neutrons. The work to be conducted at the Argonne National Laboratory as a cooperative effort, except for the histological examination of tissues which will be conducted at the University of Chicago.

SUPPORTED BY U.S. Atomic Energy Commission

5.0307, PLANS FOR A COMPARATIVE ONCOLOGY RESEARCH PROGRAM
J.H. RUST, Univ. of Chicago, School of Medicine, *Chicago, Illinois* 60637

For planning a cooperative interdepartmental research program in comparative oncology to be conducted largely within the new A.J. Carlson Animal Research Facility and its related subfacilities.

The primary elements to be under consideration will be the plans for the feasibility of comparative oncological studies in, (a) chemical and biological carcinogenesis, (b) physical (radiation) carcinogeresis, (c) localization of carcinogens (autoradiography) and the biochemical and morphological changes in cells and organs induced by these carcinogens (ultra-microscopy and light microscopy).

Secondarily, under consideration will be the plans for and/or the feasibility of comparative oncological studies, (a) feline leukemia as a model for cancer research, (b) carcinogenic capacities of radio- synergizing or related radiomimetic drugs in several animal species, (c) possible potentiation or detoxification of carcinogens by artificially induced liver microenzymes in several animal species.

5. RADIATION

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0308, RADIOBIOLOGIC STUDIES ON TUMOR TRANSPLANTATION AND IMMUNE PROCESSES
E.L. SIMMONS, Univ. of Chicago, School of Medicine, *Chicago, Illinois* 60637 (AT(11-1)-69)

This program is concerned with changes in the mammal caused by ionizing radiations administered at various ages, and modification of these changes by shielding of hematopoietic tissues during irradiation, injection of them postirradiation, or preirradiation treatment with drugs.

We intend to extend the work reported below to determine the reason for the variation in radiation sensitiveness noted including such factors as nutrition, bacteremia, stage of cell cycle of stem cells, hormonal levels. Effects of shielding, injection of tissues and drugs upon this sensitivity will also be noted. Other experiments will investigate the effects of bone marrow injections upon recovery in mice irradiated under hyperbaric conditions, correlation of date of appearance and type of tumors in mice with time of postnatal irradiation.

Results: Mice 1, 7, 14, 21, 28 and 35 days of age were X- irradiated with either single doses of 320R or with 2 doses of 160R 4 days apart. All experimental groups contained approximately 100 mice. LD50(30) figures showed that split dose treatment at 7, 14 and 28 days were significantly more lethal than single irradiations. The recovery rate was also decreased at these ages. Proliferative capacities of bone marrow cells increased progressively after birth while those of the spleen cells declined.

SUPPORTED BY U.S. Atomic Energy Commission

5.0309, PARTIAL-CELL IRRADIATION OF MITOTIC CELLS
R.E. ZIRKLE, Univ. of Chicago, Graduate School, *Chicago, Illinois* 60637

The goals of this research are to gain, through investigations featuring partial-cell irradiation, better understanding of (a) the actions of ultraviolet and ionizing radiations on eukaryotic cells, especially on the structures and processes involved in their division, and (b) the mechanisms of normal mitosis and subsequent nuclear reconstitution.

The specific tissue-culture cells are of urodeles 'Triturus, Ambystoma'. Partial-cell irradiations are achieved through microbeams of monochromatic or heterochromatic ultraviolet light and of 1.7-MeV protons.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0310, PROTECTION AGAINST RADIATION DAMAGE TO CHROMOSOMES
S. MITTLER, Northern Illinois University, School of Liberal Arts, *Dekalb, Illinois* 60115

The problem under study is that concerning the mechanism of the repair of injured chromosomes and indirectly with the mechanism of radiation injury. The approach in the proposed study is via the hypothesis that ATP is needed in the repair process, for posttreatment with anoxia and certain substances which interfere with ATP formation or the repair process results in increased radiation damage. Exogenous ATP has been shown (Mittler, S. U. S. Public Health Grant RH00140) to protect chromosomes from loss in those cells in spermatogenesis in Drosophila that are about to go into or are in meiosis at the time of radiation. The proposed project will continue to study the effect of injected ATP upon radiation induced genetic changes and the sex-linked recessive lethals, translocations, and loss of X and Y chromosomes. Information on dominant lethals and deletion of the X chromosome will also be obtained from the various cells in spermatogenesis at the time of radiation by the brood method. If ATP formation is responsible for repair, then interference with ATP formation should enhance radiation damage. Some of the factors which decrease ATP synthesis, namely, polycations, 2-4-dinitrophenol, phospholipids and calcium, will be investigated and, of course, those that aid ATP synthesis, polyanions, hypotonicity and high pH, will be tested as to the effect on radiation induced chromosome damage. Other triphosphates, namely, adenosine 5'- triphosphate, guanosine-5'-triphosphate, cytidine-5'triphosphate, uridine-5'-triphosphate, and thymidine-5'-triphosphate will be tested for ability to repair radiation induced aberrations in chromosomes.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0311, RADIATION INDUCED CHROMOSOME DAMAGE AND CELL RESPONSE
F.J. SOBKOWSKI, Southern Illinois University, School of Dentistry, *Edwardsville, Illinois* 62025

The primary objective of this project is to obtain information on the pathophysiologic processes involved in the production of late somatic effects of ionizing radiation in vivo.

Experiments are designed to simulate the temporal and physiologic conditions under which the late effects of radiation develop. The parameters to be studied include the incidence and types of radiation- induced chromosomal lesions, the kinetics of cellular and tissue regenerative phenomena and the histopathologic response of the irradiated tissue.

It is hoped that the data from this project, when correlated, will provide information that not only is presently unavailable, but that will provide a base on which additional information may be developed so that an appreciation may be gained of the mechanisms underlying the pathologic processes involved in the production of the late somatic effects of radiation.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0312, STUDIES ON BONE MARROW IMMUNOLOGIC CELL(S) IN VITRO AND IN VIVO
S.S. STEFANI, U.S. Veterans Administration, Hospital, *Hines, Illinois* 60141

Purpose: This program seeks to reduce death resulting from secondary disease after treatment of lethally irradiated mice with allogeneic bone marrow preparations.

Plan: To achieve such ends, allogeneic bone marrow cell suspensions have been treated with mild immunosuppressives to selectively eliminate the immunologically active cells without destroying the other hemopoietic components.

Results and Conclusions: Of the immunosuppressives tested in this laboratory, we have selected prednisolone, phytohemagglutinin (PHA), and anti-lymphocyte serum (ALS) for further investigation. In vitro studies of these agents showed a lymphocyte-killing effect of 20% for prednisolone, 40% for PHA, and highly variable effects with ALS. Of the three, PHA and ALS also reduced the number of red and white cell precursors. In vitro, a combination of cell irradiation (400 R X-ray) and prednisolone gave the best results in terms of selective suppression. Spleen colony assays obtained with identically treated cell suspensions correlated well with in vitro cell survivals. In vivo preliminary results suggest that PHA will render higher survival (50%) than prednisolone (30%) after lethal irradiation, but that both agents significantly reduce 'runt disease' manifestations. Our ALS preparation did not achieve higher than control survival. We feel that scrutinizing the preparative steps and final evaluation for ALS preparations may resolve these difficulties.

Future Plans: With a view toward improving the 90 day survival (overcoming the secondary syndrome) both PHA and prednisolone will be studied for individual and synergistic effects on the secondary syndrome. As soon as the difficulties with ALS have been resolved this agent will also be re-evaluated in vivo.

SUPPORTED BY U.S. Veterans Administration

5.0313, IN VITRO EFFECT OF IMMUNOSUPPRESSIVE AGENTS ON MARROW CELLS
S.S. STEFANI, U.S. Veterans Administration, Hospital, *Hines, Illinois* 60141

Purpose: The purpose of this experiment is to determine: (a) whether the lymphocytes from the blood differ from those of the bone marrow in their function and sensitivity to x-ray and to immunosuppressive agents in vitro; (b) whether the bone marrow lymphocytes are more sensitive to immunosuppressive agents than other cell lines.

Plan. After sternal bone marrow aspiration the bone marrow particles are washed, separated, and resuspended in the appropriate media. Survival of the various bone marrow cell lines after any given experiment is determined by phase contrast microscopy and by the dye exclusion technique, associated to standard hemocytometer methods and suspension smears. The response of bone marrow lymphocytes is to be compared to that of blood lymphocytes from the same patient.

Results and Conclusions. Meticortelone (10 microliter/ml) showed a decrease of about 20% in the number of lymphocytes as compared with the control untreated suspensions. Tested were also antihuman lymphocyte serum and phytohemagglutinin. The first gave varying and disappointing results, namely a cytotoxic effect not only to lymphocytes but also to all other bone marrow components. Phytohemagglutinin, although also somewhat toxic to bone marrow was particularly toxic to the lymphocyte component (40% killing effect at 2 days), as compared with the control suspensions. However, the best results were obtained when 400 and 10 microliter/ml of meticortelone were combined.

Future Plans. Due to shortage of manpower and technical difficulties, few experiments have been carried out during the last year. However, further experimentation along the above-mentioned lines will be undertaken in the near future in order to make these observations statistically valid.

SUPPORTED BY U.S. Veterans Administration

5.0314. PREVENTION OF RADIATION-INDUCED LEUKEMIA

S.S. STEFANI, U.S. Veterans Administration, Hospital, *Hines, Illinois* 60141

Purpose. The purpose of the proposed experiment is to determine whether phytohemagglutinin (PHA) causes a decrease in the incidence of radiation induced leukemia.

Plan. Male RF mice will be injected with PHA or saline and subjected to a leukemogenic dose of irradiation. They will be observed until natural death, and gross and microscopic histologic studies will be made.

Results and Conclusions. This study may lead to a possible method for preventing leukemia in humans exposed to therapeutic or accidental irradiation.

SUPPORTED BY U.S. Veterans Administration

5.0315. ELECTRON MICROSCOPE STUDIES OF IRRADIATED BLOOD LYMPHOCYTES IN VITRO

S.S. STEFANI, U.S. Veterans Administration, Hospital, *Hines, Illinois* 60141

Normal human lymphocytes were exposed in vitro to graded single doses of irradiation (from 100-20,000 R), then fixed at 15 minutes to 18 hours after irradiation and studied under the electron microscope. The early subcellular effects of irradiation and the mode of death of the lymphocytes were compared using low or high single radiation doses.

Two different types of radiation-induced damage could be observed. Up to doses of 4,000 R damage consisted of localized bleb formation of the plasma membrane, with swelling of the endoplasmic reticulum and mitochondria, and dilatation of the perinuclear space. At doses of 10,000 R and 20,000 R damage consisted of diffuse edema of the peripheral cytoplasm, with apparent maintenance of the normal aspect of the inner structures of the cytoplasm and the nucleus. Dilatation of the perinuclear space was seen in many cellular sections, sometimes with invagination of the inner nuclear membrane into the nucleus. Sections through these invaginated areas would give the false impression of intranuclear vacuoles. This electron microscope study has failed to reveal any sign of associated damage to the nucleus; specifically, there was no intranuclear vacuoles as described in previous work using light phase microscopes. Our findings contradict also previous reports indicating the 'intranuclear vacuole' to be the initial or one of the first signs of radiation-induced degeneration. The present investigation tends to implicate the plasma membrane as the site of the initial and most important events leading to lytic or interphase cellular death.

SUPPORTED BY U.S. Veterans Administration

5.0316. METABOLISM AND REMOVAL OF SR 90 AND RA 226 IN MAN

H. SPENCER, Loyola Univ., School of Medicine, *Maywood, Illinois* 60153 (AT(11-1))

Sr90 excretion and balance studies in man will be continued under strictly controlled dietary conditions. These investigations will be performed under different study conditions, the aim being to develop methods of decreasing the intestinal absorption of chronically ingested Sr90. Several antacids similar in composition to aluminum phosphate gel, which has been shown to decrease the intestinal absorption of acutely administered radiostrontium, will be used in the Sr90 studies. Another substance which will be used in the Sr90 studies in man is fluoride given in relatively large amounts. Studies of the removal of previously deposited Sr90 will be continued using compounds which have been shown to be effective in the removal of Sr85 in man such as hormones (corticosteroids, parathyroid hormone, sodium sulfate, sodium citrate, and certain chelating agents).

Results. In studies of the inhibition of the intestinal absorption of radioactive strontium in man, aluminum phosphate gel has been shown to be highly effective. These results have been recently confirmed by total body counting in this laboratory.

SUPPORTED BY U.S. Atomic Energy Commission

5.0317. ANIMAL METABOLIC STUDIES OF STRONTIUM AND CALCIUM WITH SPECIAL REFERENCE TO FALLOUT RADIONUCLIDES

J.J. ANDERSON, Univ. of Illinois, School of Veterinary Medicine, *Urbana, Illinois* 61801 ((11-1)-1339)

The purpose of the proposed work are two-fold: (1) to investigate with the aid of 47Ca the role of estrogen in calcium metabolism during late gestation and early lactation of normal and thyroidectomized cows and goats on different Ca:P ratio intakes; and (2) to complete studies initiated during the previous period designed to determine the age of swine at which 85Sr is maximally retained, as measured 200-days post- administration of the dose. The first objective has resulted from previous investigation using the goat as a model of the cow in the study of parturient hypocalcemia, a metabolic disease of the cow also known as parturient paresis and milk fever. A question arises as to why parathyroid hormone, shown by radioimmunoassay to be present at greater than normal concentration in parturient cows, is unable to stimulate the resorption of sufficient amounts of calcium from the so-called deep bone and, hence, restore blood calcium concentration to a more nearly normal level. The breakdown in the calcium homeostatic mechanism has been suggested to result from a depressed end-organ (bone cells) responsiveness to parathyroid hormone and, furthermore, that increasing titers of estrogen in later pregnancy may be involved in antagonizing the action of parathyroid hormone at the level of bone cells. The only evidence in the literature that gives indirect support to a relationship between estrogen and calcium metabolism is a report by Bach and Messervy (Vet. Rec. 84:210, 1969), who demonstrated that not only did ionic calcium fall abruptly 24 hours after estrus but also after parturition and after the administration of stilbesterol to ovariectomized cows. To test this relationship blood concentrations of estrogens will be measured by new radio-immunoassay procedures, and of calcium, total and ionic by standard methods, and additionally the 47Ca kinetic parameters of the readily exchangeable Ca pool will be measured in pregnant and lactating cows and goats, both normal and parathyroidectomized by our usual procedures. These animals will also be placed on rations containing different levels of Ca and P and some will be administered exogenous sources of estrogen.

Abnormal dietary intakes of Ca and P (4 to 1 and 1 to 3 ration) have been shown to influence the size and transfer rate of the readily exchangeble calcium pool of non-pregnant non-lactating goats.

5. RADIATION

5.0318, GENETIC EFFECTS OF RADIATION ON BIOMETRICAL TRAITS
R.W. TOUCHBERRY, Univ. of Illinois, Agricultural Experiment Sta., *Urbana, Illinois* 61801 (ILLU-35-0367)

OBJECTIVE: The broad objectives of this research were to determine the genetic effects of X-irradiation on quantitative traits in the generation immediately following irradiation and the cumulative genetic effects of irradiation in successive generations.

APPROACH: Both mice and Drosophila were used in measuring such effects. The mouse experiments consisted of matings in all combinations of females exposed to 0, 10, 20, 30, and 40 r and males exposed to 0, 50, 100, 150, and 200 r of whole body X-irradiation. This mating scheme was followed for fifteen successive generations in which data were collected on number of young per litter at birth and 38 days of age, sex ratios, and weights at 2, 8, 14, 20, 26, 32, and 38 days in both a hybrid and an inbred strain of mice.

PROGRESS: Three basic experiments have been conducted. The first to determine with mice the effects of acute doses of X rays administered each generation on hybrid and inbred populations indicates that the hybrid population was more able to withstand the accumulated effects of irradiation than were the inbreds. As the level of irradiation given each parent increased the average weight of the offspring increased but litter size decreased. In diallele experiments with seven inbred mice strains irradiation had no effect on litter size but the male progeny of irradiated males were larger than from control sires and the female progeny were smaller. In Drosophila experiments after 22 generations of selection the irradiated population showed greater response to selection for thorax length and a depression of three day egg production. Reciprocal recurrent selection was more efficient than mass selection for the two traits, of relatively low and intermediate heritabilities, studied.

5.0320, LOW-LEVEL X-IRRADIATION OF THE BRAIN DURING DEVELOPMENT - MORPHOLOGICAL, PHYSIOLOGICAL AND BEHAVIORAL CONSEQUENCES
J. ALTMAN, Purdue University, School of Science, *Lafayette, Indiana* 47907 (AT(11-1))

The histochemical and morphological maturation of the cerebellar cortex in normal rats will be studied from birth to adulthood with various enzyme-histochemical techniques and with electron microscopy. 2. This normative material will be used to determine changes produced in cerebellar maturation by its irradiation with single or multiple (1- 10K) doses of 100, 150 and 200 r soft X-ray, delivered daily from birth onward. 3. The histochemical and morphological changes that are produced by X-irradiation will be assessed qualitatively and quantitatively immediately after irradiation (1-2 days after irradiation); during the reconstitution period (4-10 days after irradiation); and, to determine terminal damage, during adulthood. 4. With the information available about the chronology of the origin of basket and stellate cells, attempts will be made to selectively destroy one of these interneurons by 'timed' irradiations (0-3, 4-7, 8-11, 12-15 days of age.) 5. Radiation induced cell pyknosis will be used as a marker technique for determining the regional rates of cell proliferation between 0-21 days throughout the entire brain. 6. We will continue our studies of the effects of low-level cerebellar irradiation on the development of motor coordination during infancy and of lasting deficits that persist through adulthood. Delayed deficits produced in the aging animals will also be studied. 7. Finally, we will begin to study the maturation of the electrical activity of the cerebellar cortex in normal and irradiated animals and the terminal functional alterations produced in the adult cerebellar cortex as a result of reduction or elimination of its interneurons by X-irradiation.

5.0321, RESEARCH PROGRAM IN DEVELOPMENTAL NEUROPSYCHOLOGY
J. ALTMAN, Purdue University, School of Science, *Lafayette, Indiana* 47907

(1) The postnatal development of the central nervous system is studied with histological, histochemical and electron microscopic techniques in rats and cats. (2) Alteration in the development of the brain as a consequence of various environmental influences are studied. Special attention is paid to the effects of low-level X-irradiation of specific brain regions on their development. (3) The factors that may affect neural recovery after early retardation of brain development are studied. (4) In all these studies attempts are made to correlate brain development with concurrent behavioral maturation. (5) Our efforts are concentrated at present on the development of the cerebellar cortex and the maturation of motor coordination under normal and abnormal conditions.

5.0322, EFFECTS OF GAMMA-IRRADIATION ON DNA TRANSCRIPTION AND RNA TRANSLATION IN PLANTS
J.H. CHERRY, Purdue University, School of Agriculture, *Lafayette, Indiana* 47907 (AT(11-1))

X- and gamma-irradiation inhibits RNA and protein synthesis in many plant tissues, so far studied. We propose that ionizing radiation directly or indirectly inhibits protein synthesis by greatly affecting the transcriptional process. Inactivation of RNA polymerase and destruction of DNA template by ionizing radiation would result in the damaging effects noted with living systems. To test the effects of gamma-irradiation on RNA synthesis, it is planned to determine the activities of chromatin-bound and soluble RNA polymerase, DNA template of chromatin and protein synthesis of sugar beet tissue. Error frequencies of RNA polymerase and template activity of the chromatin RNA product will be studied.

RESULTS: Present results indicate that gamma-irradiation of sugar beet tissue inactivates chromatin-bound RNA polymerase and reduces DNA template of chromatin. Gamma-irradiation stimulates the production of invertase and the methylation of RNA.

SUPPORTED BY U.S. Atomic Energy Commission

5.0323, EXPERIMENTAL POPULATION GENETICS IN THE LABORATORY MOUSE
D.P. DOOLITTLE, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (IND01605)

OBJECTIVE: To test the applicability of theoretical developments in population genetics to living populations, and to estimate the potential value of such developments if applied to economically important mammalian species.

APPROACH: The theory of correlated response and indirect selection procedures will be tested by attempting to increase first litter size through selection for third litter size, which is more highly heritable. Independent culling levels will be tested by selection for rapid early growth rate combined with intermediate adult weight. This study will also demonstrate the practicability of combining these two desirable traits. These specific studies exemplify the general type of experimentation intended.

PROGRESS: Since the pig and the mouse are both polytocous mammals, population genetics studies in the mouse may be particularly applicable to swine breeding. Direct selection of mice for first litter is being compared to indirect selection

through third litter size as means of increasing first litter size. Selection to combine rapid growth with medium adult body weight is proceeding as planned. Selection to compare index, tandem, and independent culling levels methods of simultaneous selection for growth rate and litter size is being initiated. Results of these studies should prove applicable to increase productivity in swine. Attempts to protect J strain mice from lethal X-rays by alloxan treatment have failed, apparently because these animals are unusually sensitive to alloxan. Mice from a four-way cross of inbred lines, which approximately replicates the cross in which alloxan radioprotection was originally shown, are being gathered for alloxan-radiation tests. Each of the four inbreds is also being tested. Mortality data on diabetic and normal mice from line MDB/Dt, which carries Hummel's diabetic gene (db), are being gathered preparatory to alloxan-radiation tests in this line. The aim of these studies is to genetically define the basis of alloxan radioprotection, as a step toward clearer understanding of the biological effects and treatment of radiation, in man and his domestic animals, in an increasingly radioactive world.

5.0324, BIOCHEMICAL ASPECTS OF ERYTHROPOIESIS IN CHRONIC IRRADIATION

C.E. BRAMBEL, Univ. of Notre Dame, School of Science, *Notre Dame, Indiana* 46556 (AT(11-1)-2005)

The objective of the research is to critically examine a modified molecular species of hemoglobin appearing during continued radiation exposure in an hypoxic environment; and, to explore the possibility that it may have its origin in the normoblasts of the erythropoietic spleen. It is proposed to ascertain whether the stem cells of the spleen are capable of biosynthesis of hemoglobin under the conditions mentioned. If this be established, the biosynthetic pathway for the modified hemoglobin would be investigated to ascertain the deviations from sequences involved in the normal entity.

Rats in a radiation environment of 70 rads/day present the following events: erythropoietic elements of the bone marrow disappear; when a critical level of anemia develops, there is emergence and proliferation of erythroid elements in the spleen with associated reticulocytosis and increased nemoglobin concentration in the peripheral blood circulation.

Evidence has accrued that new hemoglobin production has proceeded from an emerging erythroid precursor in the spleen. This process was enhanced when an hypoxic state was maintained during the course of radiation exposure. A priori, it may be predicated on this basis that the hemoglobin molecule arising under conditions of stress of anemia may be modified.

Results: Rat globin reveals 5 globin chains in non-irradiated and continuously irradiated rats in the eluates from cation exchange column chromatography with a urea gradient at low pH. Precision urea acrylamide gel electrophoresis reveals characteristic heterogeneity of all the chains. Amino acid analysis of the chains of the two groups manifests significant differences in the number of residues obtained.

5.0325, RADIATION PROTECTION AND RECOVERY IN GERMFREE ANIMALS

R. WILSON, Univ. of Notre Dame, School of Science, *Notre Dame, Indiana* 46556

Germfree animals afford a model system for assessing the effect of microorganisms on the response of mammals to wholebody ionizing irradiation. The projects that have been singled out for special emphasis this year are the treatment of secondary disease in radiation chimeras and the protection of animals irradiated in 'gut death' range by alteration of the migration rate of cells along the villus.

Attempts are being made to conventionalize germfree allogeneic radiation chimeras by controlling their environment and gradually exposing them to a normal bacterial flora. Germfree radiation chimeras are being treated with antilymphocyte serum (ALS) to obviate the tissue degeneration that occurs in these animals; a combination of treatment of ALS and an immunosuppressive agent such as cyclophosphamide may become feasible. A comparison will be made in the response to an allogeneic bone marrow transplant by an X-irradiated host and one that has been rendered immunologically incompetent by chemical immunosuppressive agents.

We are investigating the relationship between the movement of epithelial cells along the villus and radiation protection in the 'gut death' range by trying to identify the factor (s) responsible for that movement and attempting to alter that movement (e.g., control of stimuli to the muscularis mucosa in the lamina propria which is responsible for villus contraction).

5.0326, RADIONUCLIDES IN THE STUDY OF BODY COMPOSITION AND THYROID DISEASE

R.E. PETERSON, U.S. Veterans Administration, Hospital, *Iowa City, Iowa* 52240

Body composition by the isotope dilution principle is worthy of development because of the need of techniques for nondestructive analysis of the total living organism in health and as influenced by treatment of disease. For 40 k measurements to be applicable to a wide variety of clinical situations requires improved reproducibility and accuracy. Exogenous gamma-labeled metabolites present opportunities for unique turnover data, but require further clarifacation of equilibration phenomena.

I131, I125 and I123 are all utilized for clinical studies of thyroid disease yet vary widely in physical half-life and manner of decay. We wish to use them to examine the specific problem of whether the biologic effects of weak beta interactions may be greater than anticipated in the thyroid, as well as the more general problem of possible differences in biologic effects related to rad dose rate. Observing the effects of this irradiation on tritiated thymidine uptake of thyroid monolayer cultures was chosen as the system which would facilitate the clearest answer.

Thyroglobin and antibodies to thyroglobin have been invoked as involved in thyroid diseases as diverse as hyperthyroidism, chronic thyroiditis, hyperthyroidism, chronic thyroiditis, hypothyroidism and thyroid carcinoma. The hemagglutin techniques for assay have shown the diverse interrelations with thyroid disease, but have not permitted quantitation of both reactants so as to more clearly delineate the varying autoimmune factors in these diseases. The investigators have developed pilot radioimmunoassays for these factors, which now warrant application in sufficient volume to clarify their role in hypothyroidism.

5.0327, THE ACTIONS OF RADIATIONS ON SOME BIOLOGICAL MODEL SYSTEMS

G. STEIN, Hebrew University, *Jerusalem, Israel* (AT(30-1)-3242)

To investigate the action of ionizing radiations on aqueous solutions of proteins, in particular to elucidate the role of excited states and of free radical intermediates respectively. Use will be made of enzyme proteins, containing aromatic and divalent sulfur containing amino acids, to search for functional correlations between these. Use will be made of UV irradiation, and of chemically produced H atoms and hydrated electrons in the study of mechanism. Use will be made of nanosecond pulse radiolysis techniques.

Results: Elucidation of the mechanism of excited state formation and its quenching by radicals in aqueous solutions irradiated with ionizing radiations; comparison in this respect with organic solutions. Discovery of linked process involving aromatic and divalent sulfur containing amino acids in enzyme proteins, leading to inactivation by ionizing radiations and radicals.

5.0329, RADIATION DAMAGE - METABOLISM IN REPRODUCTIVE SYSTEM
V. MONESI, Univ. Degli Studi, *Rome, Italy*

The general objective of the research plan is to investigate the effects of ionizing radiation at different stages of oogenesis and spermatogenesis in the mouse and the rabbit, and to study those molecular events which might control the sensitivity to radiation damage and the repair mechanisms at definite stages of germ cell differentiation and early embryogenesis. The following problems will be investigated; a) fertilizing capacity in vitro of male and female germ cells irradiated at different stages of gametogenesis; b) analysis of chromosome abnormalities, changes in metabolic activity and rate of development in cleaving embryos in culture following irradiation of germ cells at different stages of gametogenesis. The effects observed will be correlated with specific metabolic events occurring during the irradiated stages. The existence of stable RNA molecules which could influence the developmental process and the response to radiation at subsequent stages and the presence of a 'nuclear' RNA fraction will be taken into consideration. The research project will therefore include also a) characterization by sucrose gradient analysis of the RNA classes synthesized during male meiosis, spermiogenesis, oogenesis and early embryogenesis, and kinetics studies of the RNA turnover; b) analysis of the stable RNA molecules produced during meiosis and utilized in spermiogenesis or synthesized during oogenesis and activated after fertilization, c) analysis of 'nuclear' RNA in male meiosis. Methods will be used to fractionate different cell populations of germ cells from the testis and to isolate and label in vitro with radioactive precursors oocytes free of follicular cells.

5.0332, STEM CELL PROLIFERATION AND DIFFERENTIATION
C.W. GURNEY, Univ. of Kansas, School of Medicine, *Kansas City, Kansas* 66101

The regulatory mechanisms leading to extramedullary hematopoiesis are under investigation. Mice are rendered aplastic by Sr89, a beta- emitting, bone seeking isotope which destroys the marrow but delivers less than 10r to extramedullary sites. In such animals, minimal extramedullary hematopoiesis is observed in lymph nodes, but the spleen increases in size for 16 days, after which time hyperplasia of its red pulp is adequate to sustain normal erythropoiesis.

At the present time, the factors responsible for erythroblastic hyperplasia and colony-forming hyperplasia are under investigation. If marrowprival animals sustaining erythropoiesis primarily from the spleen, are transfused and used to assay 1 unit of erythropoiesis, they are found to be less responsive to erythropoietin than normal animals. Bioassay of plasma from strontium treated mice demonstrates a very slight elevation of erythropoietin. These observations suggest continuous excessive stimulation of the splenic red pulp may be one factor in accounting for splenic hyperplasia following bone marrow destruction.

Current studies are directed at an investigation into changes in the concentration of colony-forming units in the spleen during splenic hyperplasia induced by radiostrontium administration.

5.0334, KINETIC AND BIOCHEMICAL ANALYSIS OF INTERACTING RADIATION RECOVERY SYSTEMS IN ESCHERICHIA COLI
B.S. FRIESEN, Univ. of Kansas, School of Engineering, *Lawrence, Kansas* 66044 (AT(11-1)-1686)

It is proposed that this project will be a continuation of the investigation of the physiologically-induced variations in recovery from genetic damage in strains of 'Escherichia coli' which are genetically characterized for their repair capabilities. Special emphasis will be on glucose-induced resistance (GIR) to gamma-rays and to certain drugs. The changes in the distribution in size of the DNA as a function of time after irradiation will be followed by the use of alkaline or neutral sucrose gradient centrifugation. It is proposed that DNA synthesized prior to irradiation and after irradiation be studied. From these experiments, the hypothesis will be tested that GIR reflects an enhanced amount and/or rate of repair of potentially lethal lesions.

Results: GIR to gamma-rays and methyl methane sulfonate is exhibited by rec-plus lon-plus cells and is not exhibited in rec-minus cells. As revealed by alkaline sucrose gradient centrifugation, more single- strand breaks in the DNA of GNB-grown rec-plus uvrAB or rec-plus uvr-plus cells are repaired and at an earlier time after irradiation than in NB- grown cells. No repair under either condition of growth is seen in a recA13 recB strain.

5.0335, GENETICS OF CANDIDA ALBICANS - NUTRITIONAL MUTAGENESIS AND COMPARATIVE SUSCEPTIBILITY TO ULTRAVIOLET IRRADIATION
A. SARACHEK, Wichita State University, Graduate School, *Wichita, Kansas* 67208 (AT(11-1)-1772)

The phylogenetic distribution in yeasts of light-dependent and light-independent mechanisms for recovery from ultraviolet (uv) induced damage is being examined. Specifically efforts are directed toward determining whether (a) a correlation exists between the sorts of recovery mechanisms occurring in 'Hansenula' species and the well defined phylogeny of that genus, (b) radiation repair mechanisms can serve as indicators of systematic relationships between species of the diffuse genus 'Pichia', as well as between various pathogenic species of 'Candida', (c) photoreactivation action spectra offer indications of possible evolutionary divergence of the gene for photoreactivating enzyme associated with the genus dependent nature of photoreactivation in yeasts.

These studies are designed to provide insights into (a) the potential of radiobiological phenomena as tools in taxonomic analysis of yeasts and (b) the possible ecological and systematic factors which underly evolutionary fixation of particular recovery mechanisms in various organisms.

Results: A temperature-sensitive mechanism for dark recovery from non-genetic uv damage occurs in all yeasts. Photoreactivation, however, is genus dependent. Separate mechanisms for amino acid, lipid or postirradiation respiration influenced dark recoveries have been shown to be species dependent.

5.0338, EFFECTS OF GAMMA RADIATION ON TREE SEED AND SEEDLINGS

M.B. HEASLIP, Morehead State University, School of Science, *Morehead, Kentucky* 40351 (AT(40-1))

'Pinus' a relatively radiosensitive plant genus, is a desirable indicator of lowlevel radiation stress. 'Pinus echinata', 'P. strobus', and 'P. virginiana' were planted over nuclear waste disposal trenches in 1967-68. Exposure to above and below soil level plant parts are monitored with CaF2 dosimeters. Seedlings are periodically ashed and their activity is determined to learn whether specific isotopes are accumulating. Biological effects of radiation on length and number of needles, elongation, sprouting and survival of seedlings are recorded. Of seven deciduous tree species grown from gamma irradiated seed in 1958, three species are bearing seed. Germination and survival of seed from controls and X1 generation trees are being tested for relative viability to determine long term radiation effects on populations, and gamma irradiated to test for changes in species radiosensitivity and the possibility of using recurrent irradiation as a breeding tool. First year seedlings of 'Quercus alba', 'Juglans nigra' and 'Fraxius americana' were gamma irradiated while dormant in 1966-67 or after the buds opened in 1967. Seedlings were planted in a secondary forest to ascertain the effects of irradiation on seedlings exposed to the physical and biotic stresses of their native ecosystem. The growth rates, growth patterns, and survival of seedlings are being studied to gain insight into and understanding of population dynamics.

Results: 'Pinus strobus' internode elongation was reduced to tufts of needles on scattered seedlings over burial trenches. Germination and survival of tree seed from control and X1 generation ash and red bud didn't differ significantly during a good seed year but did when stresses were great during seed development. Relative gamma sensitivity of the tree seedlings increased in the following order: ash, walnut, white oak, and physiologically active seedlings have greater gamma sensitivity than the dormant.

SUPPORTED BY U.S. Atomic Energy Commission

5.0339, A QUANTITATIVE STUDY OF THE MUTAGENIC EFFECT OF TRANSMUTATION IN DROSOPHILA & THE HONEY BEE

W.R. LEE, Louisiana State University, Graduate School, *Baton Rouge, Louisiana* 70803 (AT-(40-1)-3728)

The objective of this proposal is to determine in organisms with a true karyotype the genetic consequences of transmutation following incorporation of radionuclides into specific positions within nucleotides of DNA. The results should contribute to the genetic interpretation of molecular structure of eukaryote chromosomes and our evaluation of the genetic consequence of having radionuclides in our environment. 14C will be incorporated into DNA of Drosophila melanogaster spermatozoa and for comparison into their nuclear proteins. Spermotazoa labeled with this radionuclide will be stored in unlabeled females and any increase in the mutation rate due to radioactive decay during storage will be determined. Tests will be conducted for loss of a genetically marked Y-chromosome and sex-linked recessive lethals observed in the F2, F3, and F4.

Results to Date: Previous work by the principal investigator has shown that the transmutation effect of 32P incorporated into Drosophila melanogaster spermatozoa can be separated from the mutagenic effect of accompanying beta radiation. Transmutation of 32P in DNA of Drosphila spermatozoa did induce sex-linked recessive lethals observed in the F3 but did not produce any detectable increase in sex-linked recessive lethals observed in the F2 or in loss of genetically marked Y- chromosome.

5.0340, MUTAGENIC EFFECT OF TRANSMUTATION FROM RADIONUCLIDES INCORPORATED INTO DNA OF DROSOPHILA MELANOGASTER

W.R. LEE, Louisiana State University, School of Arts, *Baton Rouge, Louisiana* 70803 (AT(40-1))

The dilution principle is used to determine the mutagenic effect of transmutation in the eukaryote chromosome and to separate the mutagenic effect of beta radiation from transmutation. Mature labeled spermatozoa are stored in unlabeled females under conditions in which the flux from beta radiation is too dilute to be significant. The number of disintegrations per cell during storage is determined, and the mutation rate is measured before and after storage. The following genetic tests were conducted: loss of a dominant marker on the Y chromosome; sex-linked recessive lethals observed in the F 2, F 3, and F 4. Transmutation of C 14 is less effective than P 32 in inducing lethal mutations. To determine if the lower effectiveness of C 14 is due to lower energy of disintegration P 33 will be compared to P 32.

Results: Transmutation of C 14 within DNA like transmutation of P 32 does not break the eukaryote chromosome or induce lethal mutations that are present in all the cell lineage. If transmutation of C 14 is mutagenic at all, it is less effective tha P 32 by at least two orders of magnitude.

5.0342, LONG TERM EFFECTS OF PRENATAL GAMMA-IRRADIATION ON RAT BRAIN

K.R. BRIZZEE, Tulane University of Louisiana, Delta Reg. Primate Res. Ctr., *Covington, Louisiana* 70433 (AT(40-1))

Studies on the effects of prenatal, whole body, gamma-irradiation and postnatal prolonged intermittent gamma irradiation will be continued on cerebral cortex and other subdivisions of the brain in adult rats at progressively older age levels. Two different dose patterns will be employed. In one series the animals will receive a single dose of 100 R gamma-irradiation (Co-60) at 50 R/minute on gestation day 13.5. In a second series young adult animals will receive 10 R for each 17 hour day throughout the life span. Seven hours each day will be devoted to cage cleaning, feeding and watering animals in the radiation field.

Quantitative studies will include a determination, at 20 successive cortical depth levels and in individual cytoarchitoectonic cortical laminae, of cell packing density and glia/neuron index, cell and nuclear volume, and proportion of cortical tissues occupied by capillaries and by larger vessels (vascular volume). Quantitative studies on dendritic branching patterns and synaptic den-

sity of neurons in laminae III and V of cerebral cortex will be carried out and morphologic characteristics of glial cells and glial packing density will be determined in corpus callosum and medullary pyramids as compared with cerebral cortex. The accumulation and changing patterns of distribution of lipofuscin pigment in neurons and glia in cerebral cortex, cerebellar cortex and deep nuclei, and in many brain stem nuclei will be studied by fluorescence microscopy and by electron microscopy. Similar studies on glia alone will be carried out in corpus callosum and medullary pyramids.

Radioautographic studies on the cell generation cycle and cortical histogenesis in the fetal brain will be carried out with a view to obtaining information basic to an understanding of long-term effects of fetal gamma-irradiation.

A preliminary investigation will also be carried out on effects of low-dose, continuous gamma irradiation (10 R/day) on cerebral cortex of young adult subhuman primates (M. mulatta).

5.0343, ROLE OF THE RETICULOENDOTHELIAL SYSTEM IN RADIATION INJURY AND RECOVERY

N.R. DILUZIO, Tulane University of Louisiana, School of Medicine, *New Orleans, Louisiana* 70118 (AT(40-1)-3853)

Our previous studies have demonstrated the essential role of humoral recognition factors or opsonins in promoting phagocytosis. Indeed, the mechanism of recognition of 'self' and 'non-self' by macrophage cells is mediated exclusively through the interaction of the particulate and humoral recognition factor. The proposed studies will continue to clarify the sequence of events and kinetics of the phagocytic process, as well as the relative importance of humoral recognition factors on macrophage cell activity in phagocytosis and immune phenomena. The proposed study will continue to delineate the importance of opsonins in the profound phagocytic alterations observed under such conditions as X-irradiation exposure and neoplasia. Studies on recognition factor activity in neoplasia and the effect of radiation therapy on recognition factor activity will be continued. Correlations will be made relative to the possible diagnostic and prognostic use of our recognition factor assay procedure. Experimental counterparts will also be developed to assay the new concept of tumor growth and development as related to recognition factor loss. Studies will continue evaluating RE function as well as intracellular digestive and lysosomal activity of Kupffer cells derived from X-irradiated rats. In addition, the influence of radio-protective agents on irradiation- induced alterations in phagocytosis will be observed.

5.0344, EFFECT OF SPERMATOGONIAL X-IRRADIATION ON REPRODUCTIVE FITNESS OF MICE

E.L. GREEN, Roscoe B. Jackson Mem. Lab., *Bar Harbor, Maine* 04609 (AT30-1)-1979)

Genetic variations in enzymes of mice hold great promise for (1) analyses of biochemical differentiation, (2) improving the technical usefulness of the genetic linkage map, and (3) supplying insight into the evolutionary forces that tend to preserve genetic variability in natural populations. We are searching for these variations in the available inbred strains of mice.

SUPPORTED BY U.S. Atomic Energy Commission

5.0345, EFFECT OF X-IRRADIATION ON THE GERMINAL EPITHELIUM OF THE MALE MOUSE

E.L. GREEN, Roscoe B. Jackson Mem. Lab., *Bar Harbor, Maine* 04609 (AT(30-1)-1979)

The hereditary fitness of a population is expected to decrease as the accumulated genetic exposure to spermatogonial irradiation increases generation after generation. This expected result has not been observed, at least not as markedly as anticipated. The question, therefore, is how the germinal epithelium of irradiated male mice becomes repopulated with essentially normal cells. The surviving cells have means either of repair of or of escape from the radiation damage. The dynamics of the repopulation cycle will be tested by successively irradiating and mating male mice, called allophenics, produced by fusing the cleaving eggs of two genetically distinct strains of mice.

Results: We have produced 50 allophenic mice and have observed and bred them. We recently changed to a new combination of genotypes that provides a more nearly equal proportion of both parental cell types in various tissues. Irradiation of the allophenic males has begun.

5.0346, RADIATION-INDUCED CHROMOSOMAL INVERSIONS IN MOUSE POPULATIONS

T.H. RODERICK, Roscoe B. Jackson Mem. Lab., *Bar Harbor, Maine* 04609 (AT(30-1)-3671)

Our objective is to produce in mice chromosomal inversions which can then be used to uncover and study radiation-induced recessive lethals and detrimentals. Chromosomal inversions have not heretofore been defined genetically in mammals. Their production and genetic analysis would be a significant refinement in mammalian genetic technology.

We have produced paracentric inversions in male mice by exposing their testes to 900 R of X-irradiation and by searching for high frequencies of first anaphase bridges in one testis of each of their sons. The length of the inversions should be proportional to the frequency of anaphase bridges. Since there is a small but consistent frequency of anaphase bridges in all males regardless of ancestral irradiation, it is practical to keep only those inversions which are large enough to be easily distinguished from the normal bridge percentage. We have settled on 15 per cent anaphase bridges as the minimal acceptable percentage for identification and development of new inversion stocks. The particular stocks we use make it possible in a single backcross to search for linkage relations of newly induced inversions with eleven loci covering more thaf one-third of the genome.

Results: In more than 1,000 sons screened we have found several inversions, 5 of which we are studying intensively. The first inversion is in Linkage Group XIII between 'Id-1' (Isocitrate dehydrogenase-one) and 'Dip-1' (Dipeptidase-one), a distance of approximately 20 map units. The second inversion is near 'bf' (buff) in Linkage Group XVII.

5.0347, CONTROL OF CELL GROWTH, DIFFERENTIATION AND FUNCTION

C. WAYMOUTH, Roscoe B. Jackson Mem. Lab., *Bar Harbor, Maine* 04609

Using methods developed over the past 17 years in this laboratory, it is planned to move beyond the present common practice of using chemically defined tissue culture media indiscriminately for cultivation of cells and tissues other than those for which the media were designed, and to define for several normal and malignant cell types specific optimal requirements for growth, differentiation, and function. These requirements include not only medium composition, which will be examined mainly in terms of the roles of hormones and specific stimuli, and of ionic balance, but also other environmental variables, e.g. pH, gas phase, redox potential, and osmolarity. Immediate attention will be directed to the requirements of normal hepatocytes from fetal and perinatal mouse livers, and to the growth and differentiation of other cells from liver (Von Kupffer cells, granulocytes, and erythrocytes). Erythropoiesis in normal and genetically anemic mice will be compared. Other tissues selected for study in vitro are lung, kidney cortex, and medulla, as well as established heteroploid cell lines.

The indirect effects of ionizing irradiation upon heteroploid and euploid cells will be studied by examining the effects upon them of exposure to irradiated chemically defined culture media. Essential nutrients are significantly altered by such irradiation. The nature of the changes in individual components of the medium that result in cytotoxic and cytostatic effects and means of protection against these effects will be examined.

5.0348, INVESTIGATION OF POSSIBLE SYNERGISTIC EFFECTS OF NEUTRONS AND PHOTONS ON SELECTED MATERIALS

J.R. JACOBSON, U.S. Army, Nuclear Effects Laboratory, *Aberdeen Proving Ground, Maryland* 21005

Technical Objective: To investigate possible synergistic effects on neutron and photon radiation by observing the response of several solid state dosimetric materials. These materials were selected because neutrons and photons produce responses which are readily observable.

SUPPORTED BY U.S. Dept. of Defense - Army

5.0349, PARENTAL RADIATION EXPOSURE AND DOWN'S SYNDROME, WITH PARTICULAR ATTENTION TO IONIZING RADIATION AND RADAR (21)

B. COHEN, Johns Hopkins University, Graduate School, *Baltimore, Maryland* 21218 (DADA17)

Technical Objective: To study the genetic and chromosomal effects of microwave radiation specifically in relation to Down's syndrome (mongolism).

SUPPORTED BY U.S. Dept. of Defense - Army

5.0350, MORPHOLOGICAL AND HISTOCHEMICAL CHANGES IN BONE CELLS AFTER IRRADIATION - A LIGHT AND ELECTRON MICROSCOPIC STUDY

S.B. DOTY, Johns Hopkins University, School of Public Health, *Baltimore, Maryland* 21205 (AT(30-1)-3917)

Using a combination of histochemical and radioautographic techniques it is proposed that correlations can be made between enzyme response, time of irradiation insult, and alterations in cell structure. Superimposed onto this problem is the fluctuating size of the cell population due to irradiation effects on the mitotic index; however, this question can be answered by studying cell times under irradiated conditions.

Enzyme changes can be found after relatively low doses of radiation and histochemical changes have been found in bone after X-ray irradiation. Previous radioautography experiments have shown an altered cell cycle time in marrow after radiocalcium administration. We have shown with Pu-239 that the mitotic rate of the osteo progenitor cell is also affected, resulting in decreased numbers of observable osteoclasts.

Radioautography at the electron microscope level has been standardized according to the method of Caro. However, because we will be interested in determining the resolution of calcium-45 radioautography, we must determine this, and will use a system similar to Salpeter.

Doses of calcium-45 will be introduced to femoral bone via intravenous perfusion or in vitro incubation. This tissue will be fixed with glutaraldehyde or quick-frozen and prepared for electron and light microscopy radioautography.

Histochemical techniques are to be applied to these tissues containing radio calcium, to determine the activity of alkaline and acid phosphatase, adenosine triphosphatase, sulfatase and glucose-- phosphatase. The time periods under study will vary from 15 minutes to 6 months following initial injection of radio calcium. The uptake of tritrated proline, thymidine and glucose-6-phosphate will be studied during these experiments. Electron microscopy of cell structure will be studied to ascertain morphological damage.

Results: The radioautography technique for bone and calcium-45 has been successful, however the resolution may be as high as 5,000 angstroms. The various histochemical techniques are now applicable to bone tissue at the electron microscope level. It appears that the only possible method for getting large doses of calcium-45 into and around bone cells is by an in vitro method.

5.0351, CURRENT TRENDS IN SURVIVORSHIP OF RADIOLOGISTS

G.M. MATANOSKI, Johns Hopkins University, School of Public Health, *Baltimore, Maryland* 21205

The life-shortening effect of ionizing radiation as an occupational hazard of exposed physicians has been indicated through studies of mortality rates of radiologists. Physicians from other specialities with a lower risk of exposure represent an optimum comparison population since both groups enjoy similar socio-economic and medical advantages which can prolong life. A previous study by Drs. Seltser and Sartwell utilizing such a population confirmed that radiologists had a lower life expectancy than other specialists. The objective of the present proposal is to reestablish and expand the population from the previous study to include new members of the five societies. A decline in the difference between age-specific mortality rates for radiologists and for other specialists would indicate that modern safety measures were reducing the hazard of ionizing radiation.

5.0353, ULTRAVIOLET IRRADIATION OF NUCLEIC ACIDS AND RELATED COMPOUNDS

S.Y. WANG, Johns Hopkins University, School of Public Health, *Baltimore, Maryland* 21205 (AT(30-1)-2798)

Nucleic acids play an important role in cellular functions, any alteration of nucleic acids caused by irradiation could result in the production of mutagenic, lethal, and other biological effects. Any changes produced by irradiation must be physicochemical in nature, therefore, the study of the photochemistry of nucleic acids is of great importance. Our prime concern is the stepwise isolation and identification of the products from the irradiated compounds and the study of the actual mechanisms of their formation. Derivatives of uracil, thymine, cytosine, 5-bromouracil, nucleosides, nucleotides, RNA and DNA have been investigated. For identification of products, we examined not only UV, IR, NMR and mass spectra, but also the syntheses of these new compounds. In order to establish a reasonable reaction mechanism, reaction kinetics, variation of reaction conditions, intercepting reactive intermediates, tracer techniques, etc. are being used.

Results: Last year, we unequivocally established the structures of a new product derived from thymine in the acid hydrolysate of UV irradiated DNA, a photoproduct from thymine irradiated in frozen aqueous solution and a dehydration compound of the above photoproduct from thymine. Apparently, these compounds are analogous and are derived from either azetidine or oxetane derivatives. These results indicate that formation of cycloaddition products, i.e. oxetane and azetidine, is a common reaction for pyrimidine bases.

5.0354, RADIATION AND RADIOBIOLOGY RESEARCH CENTER

M.J. WIZENBERG, Univ. of Maryland, School of Medicine, *Baltimore, Maryland* 21201

The project aims to improve radiation therapy and radiobiological research through the interaction of the laboratory and the clinical area. In addition to their mutual supportive functions, individual projects are carried on in each section. The Clinical Center is continuing its study of the treatment of advanced head and neck cancer, the use of electron beam and the treatment of gynecological and urinary tract malignancies. The physics and Radiobiology Sections support the Clinical Center through computer applications to radiotherapy, in dosimetry, data storage and retrieval, and the development of techniques for improved tumor localization.

5. RADIATION

The main thrust of the radiobiological laboratory will be a continuation of its studies of heat, microwave radiation and ionization radiations on cell growth, intracellular biochemical changes, and tumor response.

5.0355, EQUIPMENT AND METHODS FOR DECONTAMINATION OF AGRICULTURAL LANDS CONTAMINATED BY RADIOACTIVE FALLOUT
P.E. JAMES, U.S. Dept. of Agriculture, Agricultural Engin. Res. Div., *Beltsville, Maryland* 20705 (AT(49-7)-1527)

This research was conducted to determine how best to treat farmland exposed to radioactive contamination. Such information is becoming of increasing importance with more widespread use of radioisotopes. During the past 8 years, experiments have tested the effectiveness of crop- removal machinery including sickle bar and rotary mower, rake, flail harvester, direct-cut forage harvester, corn picker and combine harvester thresher. Also, comparison tests of earth moving machinery have been made to obtain data on effectiveness of various machines in removing the top layer of soil. The machinery tested included road graders, bulldozers, pan scrapers, and elevating and rotary scrapers. Methods of disposal of contaminated soil so removed were investigated. These include burial of contaminated soil in the field at the end of the scraper rows and between the scraper rows as well as stockpiling the soil above the ground, and plowing the contaminated soil 3 feet below the surface with a large plow. Seeds were planted through and beneath the surface layer of radioactivity, at different depths, with no subsequent cultivation. Crops were assayed after maturity to determine the degree of radiouptake. A U.S. Department of Agriculture Handbook, 'Treatments for Farmland that has been Contaminated with Radioactive Material,' was prepared.

RESULTS: The most effective method of decontaminating farmland is to scrape the top surface and haul away the soil. A street sweeper is also effective under some conditions. Harvesting and disposing of crops is not an adequate method because much radioactive dust falls off the foliage onto the ground. Burial of contaminated top soil by deep plowing permits radiouptake by plants. Planting seeds through the undisturbed surface layer of soil also permits radiouptake, regardless of depth of planting. Neither deep plowing nor punch planting is considered to be a satisfactory decontamination method.

5.0356, ACCUMULATION AND MOVEMENT OF FISSION PRODUCTS IN SOILS AND PLANTS - I. MECHANISMS OF RADIATION DAMAGE IN PLANT CELLS
T. TANADA, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Beltsville, Maryland* 20705 (AT)

The objective of this research is to determine the mechanisms by which ionizing radiations inhibit cell growth and cause cell death. Since the effects appear some time after exposure to radiation, the biochemical location of the initial damage cannot be directly identified. However, there is a possibility that radiation damage could be due to radiation-induced deleterious effects on phytochrome (a protein controlling plant growth), or in processes immediately controlled by it. Since phytochrome controls the generation of a bioelectric potential in root tips, measurement of changes in potential is an indicator of phytochrome activity and could be an indirect method of assessing damage to the system by ionizing radiation. Initial studies will use barley shoots and mung bean tops as test materials to determine measurement methods.

Results: Using barley shoots or mung bean tops, measurements have been made of changes in bioelectric charge with exposures to red and far-red light with intervening dark periods. A system for measuring the potential indirectly by means of the centrifugal force needed to detach root tips from a glass surface is also being considered. As procedures are developed the effects of X-ray irradiations and plant hormones on the phytochrome-controlled system will be studied under standardized conditions. Part 1 of 3.

5.0357, AIRCREW VISUAL IMPAIRMENT/INJURY THRESHOLDS FROM NUCLEAR WEAPONS
R. CAVONIUS, Eye Res. Found. of Bethesda, *Bethesda, Maryland* 20014 (F41609-69-C-0027)

Technical Objective: Predictions of eye safe separation distances are required for operational analysis and mission planning and by research personnel for evaluating eye protection requirements and devices. At present such predictions are based on animal data extrapolated to humans and on limited human data extrapolated to high exposure levels. The objective of this effort is to determine threshold levels of radiant energy for permanent eye damage in humans and to assess visual impairment associated with exposure levels approaching or exceeding the permanent damage threshold values. Data will be applied in assessing man's response in a nuclear environment for S/V analysis of weapons systems. This is one of three contract efforts for essential human data.

5.0361, EFFECTS OF IONIZING RADIATION ON THE ELASMOBRANCH BRAIN
I. KLATZO, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Natl. Insts. of Health, *Bethesda, Maryland* 20014

Studies have shown the shark brain to exhibit a profound and unusual resistance to changes in vascular permeability and blood-brain barrier following severe local injury. The present investigation is to determine if such a resistance to radiation effects might be also present, and if so, what are the factors causing such a resistance. This project is almost completed.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0362, STUDY OF THE CANCER EXPERIENCE OF NON-URANIUM HARD ROCK MINERS IN THE ROCKY MOUNTAIN AREA

F.E. LUNDIN, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Natl. Insts. of Health, *Bethesda, Maryland* 20014

The purpose of this study is to delineate factors responsible for the excess respiratory mortality previously reported among men with 15 or more years experience as metal miners. Also to be determined is the relationship between lung cancer and the degree of exposure measured by length of underground employment and changing ventilation and the importance of age at first exposure, and latent period.

Company records of 120,000 metal miners have been reviewed and the occupational medical and vital statistics data have been abstracted for the 16,000 men who worked in the industry in 1937 or later, with initial employment before 1954, and with one or more years of underground service. Deaths are ascertained by reviewing the records of the companies and claims from the bureau of Old Age and Survivors Insurance. Death certificates are obtained from state health departments and classified by cause of death. The miners respiratory cancer mortality experience specific for each of the variables mentioned above will be compared with expectation generated by use of population rates for the same area.

5.0364, THE EFFECTS OF IONIZING RADIATION ON MACROMOLECULES OF BIOLOGICAL IMPORTANCE

P. RIESZ, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Natl. Insts. of Health, *Bethesda, Maryland* 20014

To investigate the molecular damage produced in biologically active macromolecules by ionizing radiation and to determine what part of the molecular damage is responsible for the loss of biological activity.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0365, TISSUE CULTURE STUDIES OF HUMAN LYMPHOCYTES

J.H. ROBBINS, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Natl. Insts. of Health, *Bethesda, Maryland* 20014

Objectives: 1) To investigate the mechanisms concerned with the control of mitosis, differentiation, function, and potentialities of normal and pathologic cells, with particular reference to the lymphocyte and cells of the lymphoreticular system. 2) To determine which cells in human peripheral blood contain 'immunologic memory' and to elucidate the nature and mechanism of action of this memory. 3) To study the effect of ultraviolet light on human blood cells with particular reference to the induction of thymidine uptake in irradiated cells and to the possible relationship of such uptake to cellular repair mechanisms.

Methods Employed: Human peripheral blood lymphocytes are cultured in vitro and stimulated to transform into large blastoid cells by factors such as phytohemagglutinin, antigens, and foreign tissue. This phenomenon of blastogenesis is evaluated by the morphologic and biochemial changes which the lymphocytes undergo. The mechanisms by which these blastogenic factors act and the culture conditions required for blastogenesis are determined. Human peripheral blood leukocytes are separated into a glass-adherent cell population, composed largely of macrophages, and into a population consisting of small lymphocytes. By recombining such populations obtained from the same and from different individuals, the function of each population is determined. Interactions and contacts between cells are examined by light and electron microscopic techniques.

Methods Employed: Human leukocytes are irradiated with ultraviolet light and then incubated with radioactive thymidine. The degree of incorporation of radioactive label into the DNA of the cells is determined by autoradiography and by scintillation counting.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0366, THE MECHANISM OF RADIATION SENSITIZATION BY 5-BROMODEOXYURIDINE IN CULTURED CHINESE HAMSTER CELLS

W.U. SHIPLEY, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Natl. Insts. of Health, *Bethesda, Maryland* 20014

5-Bromodeoxyuridine (BUdR), when incorporated into mammalian cells, yields marked potentiation of X-ray damage in vitro, in vivo, and clinically when given directly to tumors by selective intra-arterial infusion. To get a better insight into the molecular basis of radiation damage and its repair, experimental observations, yielding insight re mechanisms, were pursued on the method of BUdR-induced intracellular potentiation of X-ray killing using, and interrelating, the following techniques: a) X-ray survival parameters as measured by colony formation; b) X-ray induced physiochemical changes in the DNA and its repair as measured by alkaline sucrose gradient analysis.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0367, COMPARATIVE STUDIES OF PROTEIN RADIOLYSIS BY VARIOUS MEANS OF IRRADIATION

F.W. WHITE, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Natl. Insts. of Health, *Bethesda, Maryland* 20014

The effects of various means of irradiation on lyophilized proteins have been studied with regard to radiation damage (as expressed by effects on biological activities and losses of specific amino acids) and to distributions of carbon free-radicals among the amino acids. Thus far, gamma radiation, electrical discharge, and ultraviolet radiation have been studied. The project will be extended to include similar studies on other biological macromolecules, including nucleoproteins and nucleic acids.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0368, WEAPONRY RADIATION PENETRATION IN MATTER FOR EVALUATING ATOMIC WEAPONS' EFFECTS

M.J. BERGER, U.S. Dept. of Commerce, Natl. Bureau of Standards, *Gaithersburg, Maryland*

Technical Objective: The objective is to evaluate Naval communications systems in an atomic weapons' environment. High frequency radio communication systems used in operational circuits depend on electron and ion densities in the normal and disturbed ionosphere. Such densities are affected by the penetration of gamma rays and neutrons in air following an atomic weapon explosion. The present work will obtain the penetration of such radiation needed for estimating the effect on communications systems. The work also has application to the detection and diagnostics of atomic weapons.

5.0369, GUIDELINES FOR MINIMIZING DAMAGE TO FOOD PROCESSING INDUSTRY IN CASE OF NUCLEAR ATTACK

W.C. CROW, U.S. Dept. of Agriculture, Transp. & Facilities Res. Div., *Hyattsville, Maryland* 20782 (TF1-122A)

OBJECTIVE: Edit and make supplemental additions to handbook prepared by contractor regarding practical guidelines to minimize nuclear attack damage to food processing facilities.

5. RADIATION

APPROACH: Determine for each type of processing plant the principal types of damage that can be expected, the structural or equipment modifications and operating procedures that would minimize damage to these facilities, the pre-attack preparations that should be made to insure effective and expeditious emergency repair, the repair and maintenance procedures that should be used after attack, and the methods of handling problems of contamination. Include in the study flour mills, bakeries, meat packing plants, oilseed mills, shortening manufacturing plants, dairy manufacturing plants, food canning plants and sugar refineries. Cooperate with contractor in developing his data, supplement the study with additional information as needed, edit the report and prepare it in the form needed by Agricultural officials.

PROGRESS: Refer to TF 1-122 for progress report.

5.0370, EXPERIMENTAL ELECTROMAGNETIC RADIATION STUDIES

D.E. JANES, U.S. Environ. Protection Agcy., Twinbrook Research Laboratory, *Rockville, Maryland* 20852

The principal objectives of this program are to define the biological effects of exposure to electromagnetic radiation and provide the scientific bases for furmulating, evaluating, and supporting population exposure standards. The detailed objectives are: (1) to determine if there are genetic effects from exposure to non-ionizing radiation, (2) to determine and describe the effects of radiation on the central nervous system and glands controlling physiological integration, (3) to determine the interactions between electromagnetic fields and molecular systems that could lead to genetic and central nervous system effects, (4) to define the physical and biological parameters that determine energy absorption and hence biological hazard in the near and far field of electromagnetic radiators, (5) to examine whether data from high dose radiation studies, ionizing and non-ionizing, can be used to predict moderate or low dose effects, (6) to determine if there are cumulative effects and if there is an irreversible component to non- ionizing radiation effects, and (7) to determine whether certain subpopulations (e.g., developing fetus, aged, genetic variants) are more radiation sensitive than the normal adult.

The laboratory effort in FY 72 and 73 will be to identify the interactions between electromagnetic fields and molecular systems that lead to genetic and neurophysiological effects and to investigate directly the existence of genetic and behavioral effects. Molecular levels effects will be explored, initially at 2.45 GHz in solutions of proteins, bovine serum albumin and ribonuclease, and nucleic acids both during and after irradiation. Genetic effects, e.g., mutations, chromosome aberrations, and changes in the biological activity of DNA, will be examined in bacterial and mammalian systems, initially E. coli and Chinese hamsters. Behavioral and neurophysiological effects will be examined in small primates, dogs, and rodents at 0.4 and 2.45 GHz; dependent variables will include EEG changes and changes in performance, learning, memory, and other behavioral and physiological indices.

SUPPORTED BY U.S. Environ. Protect. Agency - O.R.M.

5.0371, MULTIPLE ENVIRONMENTAL STRESS STUDIES

C.D. LYTLE, U.S. Environ. Protection Agcy., Twinbrook Research Laboratory, *Rockville, Maryland* 20852

The object of multiple environmental stress studies is to investigate possible synergistic or addictive effects of environmental agents coupled with the effects of radiation. These environmental agents including viruses, metals such as methyl mercury and cadmium, such chemicals as DDT and NTA, and various physical agents were chosen according to their occurrences in man and his environment and the likelihood of their interacting with radiation.

Within the multiple environmental stress studies program, projects have been developed to investigate: 1) The role of viruses in radiation caused tumors using tissue culture techniques with mammalian (when appropriate, human) cells and simian or human viruses. Screening for tumor viruses in cats is done electron microscopically. 2) Synergistic effects of alpha radiation and tobacco smoke to be determined by comparing the incidence of cancer in cigarette smoking rats, non-smoking rats, and rats smoking cigarettes containing polonium-210. 3) Effects of environmental agents, such as methyl mercury, cadmium, lead, DDT, NTA, and elevated temperature on radiation responses of hamsters and rats, including tumorigenesis, teratogenesis, genetic changes, life shortening, and other physiological changes. An aquatic animal (salamander or fish) will be used in similar preliminary studies. 4) Effect of above environmental agents on the metabolism of selected radionuclides, for example, tritium.

The experimental results will constitute a bank of information on the synergistic or additive nature of the action of environmental agents on radiation effects. Biological, chemical, and physical agents of importance to radiation response will have priority, with emphasis on biological endpoints of value in estabilishing radiation protection guides and standards.

SUPPORTED BY U.S. Environ. Protect. Agency - O.R.M.

5.0372, HUMAN RADIATION STUDIES

E. TOMPKINS, U.S. Environ. Protection Agcy., Twinbrook Research Laboratory, *Rockville, Maryland* 20852

The objective of these epidemiologic studies is to quantify the risk to man of developing various disease states following exposure to radiation.

A knowledge of the risks to man associated with exposure to radiation is essential to develop a program to protect him against the hazards of radiation. All of these studies will involve the collection and statistical evaluation of data on persons exposed to radiation to determine and evaluate the risk of effects resulting from the radiation. Established epidemiological methods of collecting such as use of questionnaires, record searching, and abstracting of pertinent data will be used to obtain original and follow-up data.

The specific risks to be evaluated in the stated populations are: 1) The development of neoplasms of all organ sites in the Japanese atomic bomb survivors, patients treated with I131 for hyperthyroidism, and patients treated for malignant neoplasms with external radiation. 2) The development of thyroid neoplasms in young adults who received diagnostic doses of I131 as children, and in the young adults of Utah who were exposed to fallout from the Nevada test site. 3) The development of lung malignancies in patients who have body burdens of thorium dioxide and are continuously exhaling thoron.

The results of the three study areas will be: 1) The establishment of the relative organ sensitivity to radiation induced tumor formation. This is input data for the establishment of standards based on total cancer risk associated with radiation exposure. 2) The establishment of the dose-response curve for thyroid tumor formation following exposure of children to radioiodine. This data will be used to establish criteria for exposure of a presumed critical population group to specific radionuclides. 3) The establishment of the risk associated with continued exhalation of thoron. This data is needed to evaluate the hazards associated with long-term exposure to radon from uranium tailings.

5.0373, EFFECTS OF THERMAL RADIATION ON PERSONNEL IN NUCLEAR WARFARE

W.L. DERKSEN, U.S. Navy, Ordnance Laboratory, *Silver Spring, Maryland* 20910

Technical Objective: The overall objective is to develop the technology and information required by the military services for predicting the effects of thermal radiation on personnel in nuclear warfare. The particular objectives are to develop a mathematical model of the radiating source of casualties due to thermal radiation. To conduct experimental and theoretical studies on basic mechanisms of skin burns and other casualties due to thermal injury and to determine the hazard to military personnel in protected or semi-protected areas from toxic products given off by materials exposed to the thermal radiation pulse of nuclear weapons.

SUPPORTED BY U.S. Dept. of Defense - Navy

5.0374, OCULO-VISUAL EFFECTS - PHYSICAL STIMULUS IN NUCLEAR WARFARE
W.L. DERKSEN, U.S. Navy, Ordnance Laboratory, *Silver Spring, Maryland* 20910

Technical Objective: The objective of this work unit is to develop the technology and information required by the military services for predicting the effects on vision of viewing the blinding flash of nuclear weapon bursts and protecting personnel from vision hazards of flashblindness and retinal burns.

SUPPORTED BY U.S. Dept. of Defense - Navy

5.0375, BIOLOGY OF THE EASTERN CHIPMUNK, TAMIAS STRIATUS
D.P. SNYDER, Univ. of Massachusetts, Graduate School, *Amherst, Massachusetts* 01002 (AT(30-1)-3626)

The objectives are (1) to develop an extensive ecological knowledge of natural populations of the eastern chipmunk on permanent study plots and (2) to utilize these sample populations in controlled experiments to evaluate the effect of sublethal exposure to gamma radiation and to test hypotheses concerning population regulation mechanisms.

The principal study area is in the Green Mountain National Forest, Vermont. Three sample plots have been established at each of three elevations. This design provides control and experimental populations at each elevation and will permit the comparison of experimental treatment effects in closely related populations existing under different environments.

Treatment in the irradiation experiment is accomplished by placing each individual of the experimental population in the shielded chamber of a portable Cesium 137 source and is limited to a single exposure at levels below that which cause visible damage to treated individuals. Juvenile recruits to the population are not treated until they reach adult size and no animals are treated when in breeding condition. Ecological experiments involve manipulation of food supply and population density. Treatment effects are evaluated by comparison of ecological characteristics of experimental with control populations.

Results: Work to date has shown that it is feasible to study free- ranging chipmunks, Tamias striatus in the context of an experimental design using replicated samples of natural populations. Density, reproductive rates, juvenile recruitment, age distribution, and range of movement are parameters which have been quantified on the nine study plots and which will aid in assessing ecological effects of irradiation and the other experimental treatments.

5.0376, EFFECTS OF RADIATION ON SEMICONDUCTORS AND DEVICES
C.D. TURNER, U.S. Air Force, Cambridge Research Labs., *Bedford, Massachusetts*

Technical Objective: AF function - radiation hardening of communication statellites. Deficiency - satellites for reconnaissance, communications, early warning, navigation, and meteorology are not sufficiently hardened to radiations found in space or created by nuclear detonation. Development - evaluate the interactions of radiation induced defects in semiconductors. How development contributes - provides information necessary for the improvement of semiconductor materials and devices for hardened electronic systems. This work is concerned with mechanisms of radiation damage processes resulting from the interaction of energetic radiation with semiconductor materials and the effects of radiation-induced defect structures on the electrical and optical properties of materials. The prime importance of this work lies in its connection to the operation of spacecraft and missles in space and nuclear environment. Degradation of electronic systems can be attributed to damaging effects of energetic radiation to individual electronic devices and, ultimately, to the semiconductor material itself. However, interactions of radiation induced defects with each other and with crystal imperfections are not fully understood. Such interactions dramatically affect electrical properties and need further investigation. The study of radiation effects on semiconductor materials is one approach to improving our position of being able to predict and control the damaging effects of radiation environments to military electronic systems.

5.0377, THE BIOLOGY OF THE RETINAL PIGMENT EPITHELIAL CELL
E. FRIEDMAN, Boston University, School of Medicine, *Boston, Massachusetts* 02215

The long-term goal of this project is to increase our understanding of the role of the retinal pigment epithelium in the pathogenesis of retinal pigmentary degenerations. The morphology of the retinal pigment epithelial cell is studied by means of flat preparations of the retinal pigment epithelium as well as conventional histologic methods. Of particular interest are the effects of toxic agents on retinal pigment epithelial cells in animals. Also investigated are the effects of radiant energy on the retinal pigment epithelial cell. Thresholds to intense radiation for short periods of time have been studied. Current interest is focused on the effects of long-term illumination of the retinal pigment epithelium of the Rhesus monkey.

SUPPORTED BY Fight for Sight Incorporated

5.0378, RADIATION CARCINOGENESIS
S. WARREN, Cancer Research Institute, *Boston, Massachusetts* 02215 (AT(30-1))

Our current program on radiation carcinogenesis is currently focused on tumor induction by external radiation in perinatal mice and their descendants, the dose and dose-rate effect relationships in carcinogenesis due to internal sources in rodents, and the relationship of degenerative and reparative phenomena to the induction of cancer by external irradiation in parabiont rats. Special attention is being given to leukemia, cancer of the skin, osteogenic sarcoma and cancer of the uterus. Analyses of data will be carried out from experiments now nearly completed on effects of continuous radiation during intrauterine life, the neonatal period and adult life.

SUPPORTED BY U.S. Atomic Energy Commission

5.0379, CYTOCHEMICAL AND MACROMOLECULAR RADIATION EFFECTS
S.J. ADELSTEIN, Harvard University, School of Medicine, *Boston, Massachusetts* 02115

It is proposed to study the activity of thymidine kinase in the liver of growing mice. An attempt will be made to define the nutritional factor(s) responsible for the changing levels of soluble enzyme found on fasting and refeeding. The relation of enzyme activity to the stability of polyribosomes will be examined.

The effect of the primary aqueous radical species (OH, H, Eaq and HO2) in ribonuclease will be examined. An attempt will be made to identify the particular sulfur-containing and aromatic amino acids which are primarily degraded. The mechanisms of the radical reactions and the effects on enzyme structure will be elaborated.

5.0381, DERMATOLOGIC REACTIONS INDUCED BY SOLAR RADIATION
T.B. FITZPATRICK, Harvard University, School of Medicine, *Boston, Massachusetts* 02115

New and better approaches, applicable to large populations that will enhance the protection of normal human skin and of those diseases (nearly 30) aggravated by UV light are proposed. Exposure to sunlight is an important cause of basal and squamous cell carcinomas. Approximately 150,000 basal cell carcinomas and over 40,000 squamous cell carcinomas occur in the U.S.A. alone each year. Thousands of work days are lost by industrial employees, by agricultural workers and other people engaged in outdoor activities because of the acute sunburn or adverse cutaneous photosensitization reactions caused by certain agents (e.g. phenothiazines, tetracyclines, sulfonamides, furocoumarins etc.). There are nearly 30 diseases entities (e.g. porphyria, solar urticaria, etc.) in which exposure of skin to sun plays a major role in the pathogenesis of the disease. The net sensitivity of human skin to UV and visible energy of solar radiation often represents a balance between the damage, the extent of which depends on the dose and the sensitivity of the target; and the repair process, the extent of which varies with the genetic, the physiological state of the cell, and with the environment in which the man lives. The interaction of radiant energy with mammalian system and particularly with human skin is proposed to be investigated in an attempt to define: a) the biological target of the photon, and b) the mechanism of the damage and c) the nature of the repair process; d) the identification of the photoexcited states of the photosensitizers; e) identification of their photoproducts; f) the nature of the cutaneous damage by photosensitizers (e.g. DNA, RNA or cytoplasmic). The ultimate aim of the proposed program is the prevention of both the acute and chronic injury of human skin and of the disease caused by solar radiation.

5.0382, PROLIFERATION AND DIFFERENTIATION OF STEM CELLS
S. HELLMAN, Harvard University, School of Medicine, *Boston Massachusetts* 02115

The studies are concerned with the hematopoietic stem cell compartment, the kinetics of proliferation and differentiation, and how these can modify and be modified by radiation and cytotoxic agents. Three major areas of investigation are to be pursued: 1) Study of changing differentiation patterns of stem cells surviving radiation or other cytotoxic agents; 2) Identification and suppression of specific differentiated progenitor cells of murine bone marrow; 3) Radiation and drug response of murine bone marrow as a function of position in the cell cycle.

The techniques all study murine bone marrow assayed in irradiated syngeneic recipients. Such studies will increase our understanding of the ways by which this primal cell maintains a sufficient quantity of mature progeny both in the resting and perturbed state. From such information perhaps therapeutic regimens can be instituted to maximize tumor cell kill while preserving bone marrow function.

5.0384, EFFECTS OF RADIATION ON STATIONARY CELLS
J.B. LITTLE, Harvard University, School of Public Health, *Boston, Massachusetts* 02115

The basic objective of this research program is to gain specific information as to the response of stationary or very slowly proliferating human cell populations to ionizing radiation, particularly their response to fractionated or prolonged X-ray exposure. Most previous studies of radiation effects on mitosis and progress through the replicative cycle have been carried out with exponentially growing cells; little specific data is available related to the effects of irradiation on these processes in very slowly proliferating mammalian cells or in cells which, although capable of proliferation, are not actively progressing through the replicative cycle. Yet, such stationary cell populations are known to comprise an important component of many normal tissue complexes, as well as malignant tumors.

The cell system we will use is stationary or plateau phase cultures of an established line of human cells. We plan initially to study the proliferation kinetics of these cultures, and subsequently the effects on proliferation kinetics and net survival of single and fractionated radiation doses given alone and in combination with chemotherapeutic agents. We will also investigate in detail the capacity of these stationary cells to recover from both sub-lethal and potentially lethal radiation damage before entering cell division. In all experiments, the effects in plateau phase cultures will be compared with those observed when the same cells are irradiated during exponential growth. The results of this investigation might eventually lead to the development of more rational schemes of fractionated X-ray exposure and chemotherapy in the treatment of human cancers.

5.0385, CAROTENOID PIGMENTS AND PHOTOTOXICITY AND PHOTOPROTECTION IN BACTERIA
M.M. ROTH, Harvard University, School of Medicine, *Boston, Massachusetts* 02115

The toxicity of ultraviolet light has long been recognized. Recently it has become clear that visible light may also be toxic to cells. Visible light is also toxic to bacteria. It has also been shown that the carotenoid pigments present in certain bacteria can protect them against this toxic photosensitization. Since carotenoid pigments are found in animal cells, the question arises, can these pigments protect against the toxic actions of visible light in animal cells as they do in bacteria? Recent experiments with mice indicate that they might be able to do so. The purpose of this investigation is to study the mechanism of the toxic effects of light on bacteria, and the mechanism of the protective action of the carotenoid pigments against the lethal effects of light. The bacteria to be used in this study are: Mycobacterium marinum which produces pigments only when exposed to light; Sarcina lutea which contains carotenoids at all times; and a colorless mutant of S. lutea. This study of the fundamental aspects of photosensitization and photoprotection is a necessary prelude to the investigation of the possible therapeutic effects of carotenoids in light-sensitive diseases.

5.0386, LATE EFFECTS OF THORIUM DIOXIDE RETENTION IN HUMANS
M.L. JANOWER, Mass. General Hospital, *Boston, Massachusetts* 02114

The effects of long term exposure to chronic low dose internal emitter radiation are based largely on findings provided by previous studies of radium dial painters. There is only one other large group of humans with substantial body burdens of chronic radiation, these are patients who received Thorotrast, a radioactive contrast material which is virtually completely retained within the body. The intensive study of a large group of Thorotrast patients should make a significant contribution to knowledge of the delayed effects of radiation, and should aid in the establishment of human safety standards.

5.0387, LASER RADIATION IN PHOTOCHEMISTRY AND PHOTOBIOLOGY
K. WEISS, Northeastern University, School of Arts, *Boston, Massachusetts* 02115

The biological effects of laser radiation are of much current interest, and there is need for detailed knowledge about the interactions at the molecular level. This research is concerned with the elucidation of the nature of specific photochemical effects in biological damage caused by laser radiation. We have developed the apparatus for laser flash photolysis, which provides photochemistry and photobiology with a unique new investigative technique. The absence of stray light and the shortness of the laser pulse make it possible to detect and characterize shortlived intermediates which cannot be observed by conventional flash methods. The technique has been successfully applied to the study of some simple model chemical systems. In the present project we are using laser flash photolysis as well as conventional flash photolysis to investigate the behavior of selected molecules of biological significance which are likely to be affected by laser radiation under damage-causing conditions. The study includes multiphoton processes, which are of great potential significance with respect to the health hazards associated with non-ionizing electromagnetic radiation. We are seeking evidence for photochemical changes in biologically significant compounds under conditions which preclude direct (one-photon) excitation. The compounds selected for investigation include dyes, flavins, flavones, amino acids, purines, and visual pigments.

5.0388, THE EFFECT OF IRRADIATION ON THE BIOCHEMICAL CHANGES OF MAMMALIAN CELLS IN THE ABSENCE AND PRESENCE OF PARTICULATE MATERIAL

A.J. SBARRA, Tufts University, Saint Margarets Hospital, *Boston, Massachusetts* 02125 (AT(30-1))

This investigation will be directed toward acquiring information on the effects of low dose x-irradiation on a mammalian cell. The marker to be used to monitor the x-irradiation effect will be the overall phenomenon of phagocytosis. This approach should permit us to gain information regarding the effect of low-dose irradiation on a mammalian cell and in addition should permit us to define more precisely the biochemical reactions involved with phagocytosis.

We will attempt to identify which stages in the development of the myelogenous cell lines are radiosensitive in terms of the biochemically- defined and previously discussed phagocytic effects. Since PMN development is occurring in the marrow, information relative to the bactericidal, phagocytic and biochemical activities of sternum marrow cells would be of interest and will be undertaken.

The effect of x-irradiation on spleen cells will be continued. The possible significance of the stimulated activities noted soon after x- irradiation will be explored in relation to their possible physiological significance. Finally, we will study the relationship of H_2O_2 production and aldehyde generation to host defense post x-irradiation. Since these compounds can effect the antimicrobial activities of the phagocyte and thus susceptibility of the host to a study such as this would be of value.

5.0389, EFFECT OF X-RAY ON RESISTANCE TO LEUKEMIA IN MICE

J.A. HALKETT, U.S. Veterans Administration, Hospital, *Boston, Massachusetts* 02130

Continued studies on the effect of X-irradiation on the radiosensitive and radioresistant phases of allograft rejection have substantiated the results reported last year. Various concentrations of an AKR/J leukemic allograft homogenate were injected into nonsusceptible Swiss mice hosts which were exposed to whole body X-irradiation either at some time before or after injection. For the groups exposed to X- irradiation two days following injection, the percent nonsusceptible hosts dead from leukemia was 0% and 5% for the concentrated and one millionth dilution respctively. However for the various dilutions between these two extremes the percent nonsusceptible hosts dead was higher reaching 40% for the 1/10,000 dilution. Though Brent and Medawar have suggested that an explanation of the effects of radiation is, in the case of radiosensitivity, the loss of cellular proliferation and radioresistance occurs following the development of antibody producing cells; it would appear that additional explanations may be justified. Consideration may be given to the possibility that the concentration of the allograft is important in stimulating the rejection mechanism; that one step in the rejection mechanism may be the limiting of the allograft concentration; and the uncontrolled cellular multiplication, as in the case of the leukemic allograft occurs when X-irradiation exposure occurs before injection (radisensitive phase). A paper entitled 'The Relationship Between Various Dilutions of an AKR Leukemic Allograft and the Time of whole Body X-irradiation to the Survival of Nonsusceptible Swiss Mice Hosts' will shortly be submitted.

5.0395, THE WRITING OF A CRITICAL CREATIVE REVIEW ON THE TOPIC, RADIATION SENSITIVITY OF PLANT MERISTEMS
T.S. OSBORNE, Smith College, Graduate School, *Northampton, Massachusetts* 01060 (AT(30-1))

Plant meristems in the last decade or so have been studied from increasingly sophisticated viewpoints (radiobiology, ultrastructure, cytophotochemistry, autoradiography), and it appears timely to seek a synthesis of findings and to suggest areas where crucial knowledge is lacking. This project is a critical review of published works supplemented by research discussions, aimed at illuminating conflicts in terminology and in concepts, and at outlining topics for further research.

SUPPORTED BY U.S. Atomic Energy Commission

5.0396, EFFECTS OF IONIZING RADIATION ON MAMMALIAN SPERM AND EGGS
M.C. CHANG, Worcester Found. for Exp. Bio., *Shrewsbury, Massachusetts* 01545

It is proposed to study the effects of irradiation on (1) the fertilizing life of sperm in the male and female tract, (2) fertilizable life of eggs, (3) the ovarian oocytes of ferrets, (4) the fertilizing capacity of sperm in vitro under various conditions, and (5) the chromosomal behavior and karyotype following irradiation at very early and late meiosis during gametogenesis.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0397, STUDIES ON BIOLOGICALLY ACTIVE AMINES
Y. KOBAYASHI, Worcester Found. for Exp. Bio., *Shrewsbury, Massachusetts* 01545 (AT(30-1)2085)

The proposed program has two specific aims. First, to delineate the mechanisms underlying the radiation damage to gastric mucosa and second, to elucidate the role of histamine in gastric physiology. A connection between the radiation effect and histamine metabolism in the rat has already been established by this laboratory. The studies envisaged will be dependent on a close liaison between several scientific disciplines with particular emphasis on structure to function relationships. This program will inevitably lead to a greater understanding of the factors affecting gastric physiology and some of the findings will be highly relevant to treatment of gastric disorders in man. Both technically and conceptually the program will provide the basis on which the role of other intestinal hormones may be studied in the future. An added fall out is that these studies will provide information on the general question of hormone-enzyme interactions and their susceptibility to irradiation.

SUPPORTED BY U.S. Atomic Energy Commission

5.0398, SOME ASPECTS OF THE MECHANISM OF BACTERIOPHAGE REPLICATION
D. FREIFELDER, Brandeis University, Graduate School, *Waltham, Massachusetts* 02154 (AT(30-1)-3797)

The objective is to understand the mechanism of injection and replication of phage DNA using the bacterium, Escherischia coli and its phages, T7, and Lambda. With phage Lambda we are determining (1) whether all fragments of a broken molecule are injected and (2) the direction of normal injection. With T7 we are studying the properties of the natural termini of the DNA using preferential, P 32 labeling by polynucleotide kinase. Since we choose to interfere with some of the normal processes by X-irradiation, we are continuing our studies of the molecular alterations in DNA produced by X-rays. We are initiating a study of the mechanism of induction of lysogenic phage.

5.0399, HUMAN EYE LASER THRESHOLDS FOR AIR FORCE OPERATIONAL PERSONNEL
D. SHEENA, Whittaker Corporation, *Waltham, Massachusetts* 02154 (F41609-70-C-0006)

Technical Objective: Air Force use of laser systems requires quantitative description of laser eye effects to establish safe exposure limits. Most work is done in experimental animals. Additional confidence is required in current ability to extrapolate data from animals to aircrews. To address the deficiency, this effort will be to determine energy levels of laser radiation necessary to produce minimum threshold retinal lesions and permanent functional damage in human eyes for the establishment of Air Force safety criteria.

SUPPORTED BY U.S. Dept. of Defense - Air Force

5.0400, STUDIES OF RADIATION DAMAGE TO BIOLOGICAL MATERIALS
R.S. ANDERSON, Clark University, Graduate School, *Worcester, Massachusetts* 01610

This research will involve detailed studies of the effects of various radiations in producing radiation damage in molecules of biological interest. To secure maximum understanding of the radiation damage process, single crystals will be studied. Radiation-produced, trapped radicals will be detected, identified and examined using the highly sensitive electron spin resonance technique.

It is planned to study the effects of (1) gamma rays, (2) ultraviolet light, (3) laser beams, (4) ultrasonic beams and (5) hydrogen atoms. Compounds to be studied include (1) those of general biological interest, such as amino acids and mono- and dicarboxylic acids, (2) organic compounds having unsaturated chemical bonds, hence susceptible to hydrogen atoms, and (3) possible radiation protective agents such as sulfur and selenium compounds.

From this research it will be possible to locate the point in the molecule at which the damage occurred, and to determine a number of the chemical and physical properties of the damaged molecule. The relative radiation sensitivity of the various molecules will be established.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0401, EFFECT OF IONIZING RADIATION ON BIOLOGIC HALF-LIFE OF 57COBALT IN THE MOUSE
K.L. BECK, U.S. Veterans Administration, Hospital, *Allen Park, Michigan* 48101

Only limited information is available on the biologic half-life of radiopharmaceuticals used in medicine today. Biologic half-life (T1/2b) varies with the rate of metabolism, is affected by diseases of metabolism, and is altered by external factors including irradiation. The specific aim was to show the effects of external ionizing irradiation on the biologic half-life of Tc99m sulfur colloid.

The effective and biologic half-lives were determined for normal healthy female mice given 1 microCi doses of Tc99m sulfur colloid. The short physical half-life interfered with accurate measurement of the biologic half-life.

The study was continued using the relatively long half-life nuclide Co57. Three groups of mice received 0.25, 0.50 or 0.75 of the LD 50/30 dose of external gamma irradiation (100 R/m). These and nonirradiated controls were injected with 2 to 4 microCi 57Co and the effective and biologic half-lives were determined. Another group of mice was irradiated 338 hours after their injection with Co57.

The radioactivity in all the mice decreased to approximately 70 per cent 24 hours after injection. Thereafter radioactivity continued to decrease at a slower rate. The biologic half-life was 17 plus or minus 0.3 days in unirradiated female mice. The T1/2b was decreased slightly with increasing external irradiation except that the T1/2b was increased to 26.4 days for the mice irradiated at 338 hours after injection.

SUPPORTED BY U.S. Veterans Administration

5.0402, EFFECTS OF RADIATION AND OTHER FACTORS ON THE DEVELOPING FORM AND FUNCTION OF THE NERVOUS SYSTEM
S.P. HICKS, Univ. of Michigan, School of Medicine, *Ann Arbor, Michigan* 48104 (AT(11-1))

This research studies effects of brain injury by radiation and other means in early life on subsequent structural and functional development, and compares these with effects of similar injuries in adulthood. It aims to determine limits of residual function set by various injuries to different parts of the nervous system.

SUPPORTED BY U.S. Atomic Energy Commission

5.0403, AREA PROGRAM IN POPULATION GENETICS
J.V. NEEL, Univ. of Michigan, School of Medicine, *Ann Arbor, Michigan* 48104 (AT(11-1)1552)

This is a multidisciplinary project in population genetics which, at the one extreme, involves extensive field work among some of the most primitive Indians still in existence and, at the other extreme, attempts computer simulation of many aspects of the breeding structure of Indian populations, in an effort to explore many questions concerning inbreeding levels, genetic drift, stabilizing selection, etc., not susceptible to deterministic formulations. A particular effort is being made to determine how man's interaction with potential pathogens differs in this environment from that in the more familiar culture of civilized man. This year especial foci of interest will be, 1) a search for the cause of the large amount of chromosomal damage discovered last year, 2) completion of the collection of demographic data in areas previously contacted, and 3) penetration of several new areas.

In addition, efforts will continue to develop and refine new genetic systems of value to population genetics (Cp,Lp,Xm,Ag,Gm) and to understand the basis for species similarities and differences in isozyme patterns.

Finally, the Program includes provisions for the continuing participation of Dr. Blooom in the cytogenetic studies of the Atomic Bomb Casualty Commission.

Results: Report by approximately 50 papers on inbreeding effects, biochemical variants, and population genetics of the American Indian.

SUPPORTED BY U.S. Atomic Energy Commission

5.0404, X-IRRADIATION OF BRAIN OF PATIENTS WITH MULTIPLE SCLEROSIS - CEREBROSPINAL FLUID LIPOPROTEINS - WHITE MATTER GANGLOIDS
W.W. TOURTELLOTTE, Univ. of Michigan, School of Medicine, *Ann Arbor, Michigan* 48104

1. Will X-irradiation of the brain of patients with multiple sclerosis decrease the immunoglobulin-G concentration, leucocyte count, lipids and bromide ion concentration in the cerebrospinal fluid and significantly change the neurological function?

2. Are the lipids in the cerebrospinal fluid protein bound? Are they abnormal in multiple sclerosis cerebrospinal fluid?

3. Are the gangliosides in the white matter compartmentalized to the axoplasm? Are they abnormal in plaques and in surrounding normal appearing white matter?

SUPPORTED BY National Multiple Sclerosis Society - N.Y.

5.0405, CYSTEAMINE AND X-RAYS PRENATALLY - BEHAVIOR OF THE RAT
J.M. ROBERTS, Univ. of Detroit, School of Dentistry, *Detroit, Michigan* 48221

There is comparatively little behavioral data (learning, emotionality, activity level, sensory responsiveness, etc.) available in the literature in the area of protective agents and radiation damage as observed postnatally in the prenatally-irradiated animal.

The purpose of the proposed project is to: (1) elucidate the role of the fetal adrenal cortex in the maternal organism's biological reaction to the stress of radiation; (2) clarify the role of cysteamine in regard to radiation protection of the fetus when given either before or after irradiation of the pregnant mammal; and (3) to extend our investigations of the effects of radiation on measures of central nervous functioning.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0406, PHYSICAL MECHANISMS IN THE INACTIVATION OF PROTEINS BY RADIATION
E. KUNTZ, Michigan State University, School of Natural Sciences, *East Lansing, Michigan* 48823 (AT)

We propose to extend our study of the preferential destruction of cystinyl residues adjacent to tyrosines in ribonuclease by UV to ionizing radiations. Investigations on the nature of the interactions between aromatic groups and peptide or cystinyl groups will continue. Photosensitized crosslinking in proteins will be investigated.

Results: Evidence for preferential destruction of cystines adjacent to tyrosines in ribonuclease irradiated by UV light. Interactions between aromatic residues and peptide bonds or cystinyls to quench fluorescence and phosphorescense. Inactivation of trypsin by slow electrons.

SUPPORTED BY U.S. Atomic Energy Commission

5.0407, BIOCHEMICAL CHANGES CAUSED BY RADIATION INACTIVATION
E. KUNTZ, Michigan State University, School of Natural Sciences, *East Lansing, Michigan* 48823

Long Range Goal: To understand the molecular processes in proteins and nucleic acids which are initiated by radiation products and result in loss of biological activity. Ultimately, we want to be able to predict what type of energy transfer, localization and damage will result from excitation of nearby solvent or of any of the components in a complex structure such as a chromosome.

Immediate objective: The radiation induced processes occurring in condensed systems such as protein films and cellular structure such as mitochondria will be compared to those which occur in dilute solution of enzymes and nucleic acids.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0408, FACTORS RESPONSIBLE FOR CHANGES IN RADIOSENSITIVITY OF EMBRYONIC TISSUES
L.W. MERICLE, Michigan State University, School of Agriculture, *East Lansing, Michigan* 48823 (AT(11-1)-1400)

Changes in radiosensitivity and patterns of response undergo marked changes during the proembryo period in barley and floral bud development in 'Tradescantia', with changes, in the latter, also associated with inflorescence aging and alteration of the environment. The purpose of this research is to delineate those factors (inherent or external) which are responsible for, or capable of modifying, the radiosensitivity in these embryonic tissue systems, and to determine insofar as possible the mechanisms involved. Microspectrophotometry measurements of changes in nuclear components of barley proembryos are being carried out to find explanations for their puzzling radiation response behavior. Confirmation of DNA data is being sought and study extended to include basic and acidic proteins. Somatic mutations for flower color at the delphinidin, D, locus in clone 02 'Tradescantia' probably constitute the most radiosensitive biological indicator known. Evidence is being sought as to the specific cytogenetic mechanisms involved. Receiving current attention are those responsible for (a) spontaneous mutations, (b) ones actuated by temperature extremes or other environmental variables, and (c) dissemination of the product(s) of a single mutational event (in a linear structure, such as a stamen hair) which results in the formation of multiple, discrete, mutant sectors separated by non-mutated cells.

Results: Preliminary data on DNA content, coupled with absence of cytological evidence of endopolyploidy, indicate the probable presence of polyteny in early proembryos of barley. Somatic mutations at the D locus often involve chromosome aberration, but ones of spontaneous origin seem to arise by mechanisms such as mitotic crossing-over or gene mutation which do not yield micronuclei. Diurnal differences of 0-35 F- deg. have no readily detectable effects on spontaneous mutation rate, but increasing the range by 5 F-deg. raises mutation rate 9-fold. Individual stamen hairs containing multiple mutant sectors arise early in hair

development, not when mutation rate is highest, indicating their probable origin as single mutational events.

5.0409, MECHANISMS OF ION UPTAKE AND TRANSPORT BY ABOVE GROUND PLANT PARTS

S.H. WITTWER, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00088)

OBJECTIVE: Resolve mechanisms of foliar absorption of mineral nutrients and fallout materials. Accurately determine foliar absorption rates, not biased by transport, of various mineral nutrients and constituents of fallout for several crop plants. Resolve mechanisms of transport and redistribution in the plant, and underlying factors responsible for degrees of mobility and for immobility of foliar absorbed nutrients.

APPROACH: Studies will be initiated relative to factors affecting absorption and mobility of foliar applied cesium 137. The mobilization of foliar applied nutrients by the developing fruit of the tomato variety Farthest North (highest fruit/foliage ratio of known varieties) as influenced by graft unions and certain growth substances will be followed. Influence of root temperatures on foliar absorption of specific nutrients by several species will be determined.

PROGRESS: Review papers on foliar absorption and phosphorus nutrition were prepared and published. Factors affecting the penetration of iron carriers through cuticular membranes of Euonymus and tomato fruits and isolated tobacco leaf cells were identified. Zinc and calcium uptake and distribution studies were conducted with beans and special reference given to the Sanilac and Saginaw cultivars. The mechanism of uptake of zinc in bean tissues was passive. DMSO enhanced zinc uptake, but concomitantly reduced respiration and RNA and protein synthesis. There were differential subcellular accumulations of zinc and calcium which were variety dependent.

5.0410, EFFECTS OF IRRADIATION ON LICHENS AND LICHEN-FORMING FUNGI AND ALGAE

F.H. ERBISCH, Michigan Technological Univ., School of Science, *Houghton, Michigan* 49931 (AT-(11-1)-2085)

The objective of this study is to determine if the symbionts (fungi and algae) of Cladonia sylvatica, a fruticose lichen, are more gamma radiosensitive when in association, forming the intact lichen, or when separated from each other.

In 1968 several crustose lichens and one fruticose lichen were irradiated at the Lawrence Radiation Laboratory of the University of California. No physical or cellular damage was noted in the irradiated material. Later a more intensive study with Cladonia sylvatica was undertaken. Physical damage was first observed at 2,000 Kr. Oxygen consumption of irradiated material (0.1 to 1,000 Kr) varied, somewhat, for the first week after irradiation, but by the third week it paralleled that of the control. Phycobiont damage within the intact lichen was first noted two weeks after 100 Kr doses, and immediately after doses of 1,000 and 2,000 Kr. No more than 5% of the phycobiont cells appeared damaged. Chronic irradiation studies, at the North Central Forest Experiment Station at Rhinelander, Wisconsin have also indicated that Cladonia sylvatica is highly gamma radioresistant.

Chronic irradiation studies at Rhinelander are continuing with field and cytological observations being made periodically of the lichen clumps that were transplanted into the field during 1969.

Acute radiation studies using both the intact lichen and the individual symbionts will be conducted to determine the effects of irradiation on respiration, photosynthesis, membrane permeability, and cell structure. Uniform patches or clumps of Cladonia 30-40 centimeters in diameter, will be used for each series of experiments. Typical Warburg manometric techniques will be used to study photosynthetic and respiratory rates. Membrane permeability will be measured by rate of uptake and incorporation of 32P into the cells. Thin sections and squashes will be prepared for examination with phase contrast and Nomarski optics. These slides will be examined for choloroplastid and nuclear shape and volume changes along with chromosome and other cellular damage within the symbionts.

5.0411, BIOCHEMICAL STUDIES IN THE OCULAR LENS IN RELATION TO CATARACTOGENESIS

V.E. KINSEY, Oakland University, Inst. of Biological Sciences, *Rochester, Michigan* 48063 (AT(11-1)-2012)

The mechanism by which the level of glutathione falls in lenses exposed to ionizing radiations will be examined by investigating possible alterations in the permeability characteristics in lenses at intervals following X-irradiation.

Further studies are proposed to separate the effects of the electrical and chemical potential on the transport of ions in and out of the lens. A mathematical model which considers the lens as a pump-leak system derived from classic enzyme kinetics and diffusion theory has been devised which describes the parameters of the system governing active transport and passive diffusion across membranes. Multiple cross saturation experiments are planned to determine the effect of concentration of K, Rb and Cs in bathing media and the movement of these ions in and out of cultured lenses to test the validity of the model and evaluate the parameters of the system. This procedure will make it possible to decide whether one or more carrier systems participate in the transport of these ions and whether inhibition is competitive or non-competitive. It will also afford information concerning the effect of concentration on the permeability characteristics of the lens.

Further studies are also planned to explore the implications of the translenticular current, apparently produced by the active transport of sodium across the lens, as well as investigations on the transport and synthesis of amino acids by this organ.

Results: A current of 15 Micro Amperes due probably to movement of Na flows across the lens through a resistance of approximately 1250 ohms. The open circuit voltage is about 20 mV. A mathematical model of the pump-leak system of transport in the lens, of usefulness in evaluating the parameters of the system, has been devised. The active transport of taurine in the lens has been characterized.

5.0412, CELLULAR PROLIFERATION AND REGENERATION FOLLOWING TISSUE DAMAGE

C.V. MARDING, Oakland University, School of Arts, *Rochester, Michigan* 48063 (AT)

The goal of this program is to further elucidate the mechanisms that control mitosis and cellular migration in normal and injured lenses. This should lead to a better understanding of those phenomena which are related to mitosis and migration: Differentiation, regeneration, growth, wound-healing, and response to injurious agents such as radiation. With regard to the lens, it should increase our understanding of the mechanisms of cataract formation. The specific aim of this project is to delineate the pattern of macromolecular synthesis and ultrastructural changes, i.e. changes in cell-to-cell relationships, which precede the initiation of cell division in the epithelium of lenses which have been induced to divide as a result of injury or culture of the lens in media containing rabbit serum or insulin. An additional aim is to characterize the factor(s)in serum which engenders mitosis and migration and to determine its mode of action. Investigations will be focused upon changes in ultrastructure of the injured epithelium at different stages of the cell cycle during wound- healing. A further characterization of the mitogenic serum factor(s), (Harding et. al., 1968, J.C. Physiol., 72, 213-220) and the effect of radiation on serum factor production will be evaluated. The ultrastructural and metabolic changes which occur during triggering of the cell cycle in vitro and which accompany the re-establishment of the G-O state will be investigated. We also propose to study the mechanism by which insulin triggers cell division in the cultured lens (Reddan and Harding, 1969, J.C., 43, 114A).

SUPPORTED BY U.S. Atomic Energy Commission

5.0413, EFFECTS OF IONIZING RADIATION & OTHER ENVIRONMENTAL FACTORS ON BREEDING BEHAVIOR,

ACTIVITY PATTERNS & MOVEMENT OF SELECTED VERTEBRATES

J.R. TESTER, Univ. of Minnesota, Museum of Natural History, *Minneapolis, Minnesota* 55455 (AT(11-1))

The objectives are to determine effects of ionizing radiation and other environmental factors on breeding behavior, activity patterns and movement of selected vertebrates and to interpret these effects in terms of their possible influence on population dynamics. LD50-30's will be determined when possible for the species under investigation. Studies on the pair-formation in Green-winged Teal and on territorial behavior in Shovelers are being concluded. The effects of ionizing radiation on vocalizations in mallards will be initiated. Studies of the biological, behavioral and physical factors affecting home ranges of snowshoe hares, cottontail rabbits, raccoons, red fox, striped skunks and white-tailed deer under natural conditions are being carried out using an automatic radio tracking system. Also, methodology to monitor the heat budget of these mammals will be developed, in an effort to expand the parameters used to measure the effects of sublethal doses of radiation.

5.0414, RESPONSES OF PROTEIN SYNTHESIS TO ENVIRONMENTAL STRESSES AND RESULTANT MORPHOLOGICAL CHANGES

G.N. BROWN, Univ. of Missouri, Agricultural Experiment Sta., *Columbia, Missouri* 65201 (MO00606)

OBJECTIVE: Investigate changes in characteristics of transfer ribonucleic acids (tRNA) to changes in levels of temperature and ionizing radiation. Responses of synthetic rates of tRNA, messenger RNA (mRNA), and ribosomal RNA (rRNA) to changes in levels of temperature and ionizing radiation. Responses of synthetic rates of some enzymes fundamental to growth and development to changes in levels of temperature and ionizing radiation. Relationships between these objectives and resultant morphological changes. Changes in objectives during senescence following extreme changes in levels of temperature and ionizing radiation.

APPROACH: Mimosa (Albizzia julibrissin Durazzini) and other hardwood seedlings will be exposed to temperature and ionizing radiation stresses. Quantitative and functional responses of total RNA, DNA, tRNA, mRNA, rRNA, and some fundamental enzymes, all pertinent to protein synthesis will be determined. Morphological changes also will be observed and related to early changes in protein synthesis mechanisms following exposure to temperature and ionizing radiation stresses.

PROGRESS: Changes have been documented in transfer RNA profiles during maturation and changes in growth rates of mimosa epicotyl tissues, and are being reported in a paper currently in press in Plant Physiology and a paper currently in review with Plant and Cell Physiology. Quantitative changes in mimosa epicotyl RNA fractions following gamma irradiation have been reported in a completed MS thesis and a paper in preparation for publication in Biochim. Biophys. Acta. Characterization of an unusual soluble RNA fraction in mimosa epicotyl tissues is in preparation for publication in Biochim. Biophys. Acta. A technique for purification and separation of ribosomal units using higher plant tissues has been perfected, and is in preparation for publication in Plant Physiology. Progress has been made on a study of RNAse activity in response to winter hardening. A study on quantitative changes in RNA fractions in red pine embryonic and megagematophytic tissues during germination is almost completed. Finally, after three years of work a technique has been modified to the point of yielding satisfactory results in an assay for amino acid acceptance by specific transfer RNAs.

5.0415, STUDIES ON THE MECHANISM OF ULTRAVIOLET INACTIVATION OF ENZYMES

C.A. GHIRON, Univ. of Missouri, School of Medicine, *Columbia, Missouri* 65201 (AT(11-1)1667)

The purpose of this research proposal is to investigate the mechanism of ultraviolet inactivation of enzymes. This will be done by studying the rate of enzyme inactivation and amino acid residue destruction as a function of illuminating wavelength, of protein conformation, and of radical scavenger concentration. The enzymes to be studied are trypsin and ribonuclease. In addition a search for acid labile photoproducts will be instituted. For this purpose the ultraviolet sensitivity of the peptide hormones angiotensin and vasopressin will be studied.

SUPPORTED BY U.S. Atomic Energy Commission

5.0416, EFFECTS OF X-RAYS ON NORMAL AND MALIGNANT CELLS

L.J. TOLMACH, Washington University, School of Medicine, *Saint Louis, Missouri* 63110

Study will continue of (a) phase-dependent fluctuations in the response of cells to X-rays; (b) potentially lethal damage and the modification thereof by pre- and post-irradiation treatment of cells with various agents; (c) deficient DNA synthesis associated with physiologic cell death following X-irradiation.

5.0417, MATHEMATICAL BIOLOGY OF NEOPLASTIC GROWTH

R. WETTE, Washington University, School of Medicine, *Saint Louis, Missouri* 63110

This project is concerned with the development and analysis of probabilistic mathematical models representing the growth, dissemination, and radiation response of solid tumors.

The growth of solid-tumor cell populations is modeled as a stochastic birth, death, elimination (of dead cells), and emigration (of live cells) process under the assumption that the respective parameters depend (1) on the space state of the population and (2) on the spatial location of cellular regions in the tumor.

The cellular radiation response is modeled as a stochastic process in which hypothetical cellular replicating units can be reversibly deactivated or irreversibly damaged. This model is sought to represent variable radiosensitivity during the phases of the cell cycle, radiation induced mitotic delay, and latent lethal damage.

It is proposed to then compound the growth process with the cellular radiation response model to obtain a model to represent the radiation response of a tumor cell population. The aim is to quantitatively predict the expected behavior of a solid tumor under radiotherapy so as to further clinical cancer management.

5.0418, BIOCHEMICAL AND IMMUNOLOGICAL STUDIES OF ENZYMES OF METAZOAN PARASITES

D.L. FERGUSON, Univ. of Nebraska, School of Agriculture, *Lincoln, Nebraska* 68503

The proposed research will primarily involve investigations of enzymes of Ascaris suum and Haemonchus contortus. Where possible, a comparative biochemical and immunological approach will be employed in order to better characterize the enzymes of the metazoan parasite in relation to its host animal. Further investigations of proteins having the same enzymatic activity from various stages of the life cycle of the parasites and from the various tissues or cellular fractions of the parasite will be made concerning their biochemical, physical and antigenic properties. The natural host animal for each parasite will be used to test their antigenic properties. This will include a study of the type, sequence of production, and amount of immunoglobulin (IgM, IgA, or secretory IgA) stimulated by these enzyme antigens and whether these immune globulins inhibit the enzymatic activity of the antigen. Resistance of the immunized animals to infection by infective larvae will be tested.

Another phase of the proposed research will involve the investigation of possible changes induced in enzymes of larvaes of parasites (particularly Ascaris suum) on exposure to X-irradiation. Such a study will necessarily involve a comparison of enzymes of normal to X- irradiated larvae.

5.0420, AEC RADIATION EFFECTS PROGRAM

A.A. MOGHISSI, U.S. Environ. Protection Agcy., Western Environ. Research Lab., *Las Vegas, Nevada* 89114

The objective of this program element is to conduct laboratory and field investigations to aid in determining the potential hazard to humans and the environment resulting from nuclear testing activities.

The potential hazard from selected radionuclides such as might be released to the environment from nuclear sources, e.g. testing activities and power reactors, are investigated in the laboratory and in the field. Radionuclide metabolism in beef and dairy animals, in plants, soil-plant relationships, and transport are included in this project.

The laboratory greenhouse facilities, microplots, and farm and dairy facilities are used in this project. The various components of man's food chain are considered during this study as well as the transport, distribution and exchange within and between these components. The principal pathway considered is the air-forage-cow-milk chain for radionuclides of interest.

SUPPORTED BY U.S. Environ. Protect. Agency - O.R.M.

5.0421, AEC ANIMAL INVESTIGATION PROGRAM

D.D. SMITH, U.S. Environ. Protection Agcy., Western Environ. Research Lab., *Las Vegas, Nevada* 89114

This project is conducted to evaluate the uptake and distribution of radionuclides in tissue and bone samples from domestic and game animals in the environs of nuclear testing and to investigate claims of radiation damage to animals. Special objectives include: a) The determination of tissue concentration of fresh and/or aged fission and activation products in bovine and mule deer which range on the Nevada Test Site. b) To study deer migration patterns on the Nevada Test Site as related to environmental parameters, e.g., season, precipitation. c) To maintain a beef herd on the Nevada Test Site and maintain individual health records on the animals.

The radionuclide distribution in animals that are potential components of man's food chain will be studied. Alleged damage to domestic animals from AEC activities will be investigated.

Bovine samples are collected from the beef herd ranging on the Nevada Test Site as well as from animals purchased from ranchers in the near off-site areas. Mule deer are sampled from periodic hunts as are other species, e.g., doves, chukar, ducks, and an occasional road kill of such animals as desert bighorn sheep. Investigation of alleged damage to domestic animals is conducted by veterinarians.

SUPPORTED BY U.S. Environ. Protect. Agency - O.R.M.

5.0422, ECOLOGY OF HOT CREEK VALLEY - VEGETATION AND SOIL RESPONSE TO UNDERGROUND DETONATIONS

P.T. TUELLER, Univ. of Nevada, Agricultural Experiment Sta., *Reno, Nevada* 89507 (NEV00699)

OBJECTIVE: Investigate influences of AEC underground testing on the flora, funa, and soils in the Hot Creek Valley and surrounding areas.

APPROACH: An ecological resource inventory of Hot Creek Valley is in progress. Determine underground testing influence on native vegetation and soils, the following areas will be studied: Change in species composition. Change in water uptake capacity as a result of root damage. Possible accumulation of radioactive materials by native species. Soil moisture patterns before and after detonation. Possible root-soil interface damage. Revegetation and denuded areas will be studied. Suitable adapted species and artificial revegetation methods will be determined.

PROGRESS: Hot Creek Valley has been mapped by plant communities. Eighty-five soil descriptions were made throughout the communities in the valley. Soil-vegetation correlations are being developed. Permanently located plots have been established on transects surrounding two test holes. Predetonation species composition, cover, frequency, production and soil moisture data have been gathered from these plots. Species trial and seeding method plots were seeded in the spring and fall to obtain vegetation data. Phenological and production data has been gathered from two major plant communities in both Hot Creek and Reveille Valleys. Predetonation mult-spectral aerial photography has been obtained and is being analysed for the UC-3 and UC-4 study areas. A plant collection has been started. Two hundred species were collected, named, and mounted. Preparations are being made to follow changes in the growth of woody plants by annual ring width analysis and sapflow movement. Preliminary data has been collected on a variety of other ecolgical parameters.

SUPPORTED BY Nevada State Government

5.0423, EFFECT OF URANIUM ON THE TRACHEOBRONCHIAL TREE

O. AUERBACH, U.S. Veterans Administration, Hospital, *East Orange, New Jersey* 07019

We have received 201 lung specimens from Dr. Saccomanno in Grand Junction, Colorado, the majority of which are from uranium mine workers. These lungs have been processed and interviews from the families of the individuals are being sought.

During the year several pulmonary cytology task force meetings were held in Salt Lake City and in Grand Junction to discuss the objectives and status of the study. Among other things it was observed that normal sputum cells are found in some individuals and not in others regardless of respiratory irritants; that inspired irritants such as radon, cigarette smoke, smog, silica, etc., produce sufficient irritation to the respiratory mucosa causing alteration of tall columnar cells and squamous cell metaplasia; that continued irritation of the bronchial respiratory epithelium may cause progressive changes in the lining cells which are recognizable in sputum cells, and these aberrations progressively approach all characteristics which closely simulate characteristics of malignant cells and the more atypical the respiratory epithelium becomes, the more likely the possibility of malignancy developing becomes; that the above cellular characteristics are reversible, statistically, as well as actually, and can be demonstrated cytologically. Synergism of chronic irritants is obvious in the etiology of cancer of the lung and deserves much more research attention.

A result of the group meetings was the decision to classify the tumors according to the World Health Organization.

SUPPORTED BY U.S. Veterans Administration

5.0424, STUDIES OF THE DYNAMICS OF CARDIAC DEVELOPMENT

S.H. GILANI, New Jersey Coll. Med. & Dent., School of Medicine, *Jersey City, New Jersey* 07304

Studies are concentrated on the development of the heart in chick embryos with special emphasis on the arterial outflow tract (ventricular outflow tract: bulbus arteriosus and its derivatives); the tract is the most common site of congenital heart disease.

The effects of various teratogenic agents like X-rays, hypothermia, thalidomide and nicotine on the heart development are being investigated by treating the embryos at 2-4 days of incubation--a critical period in the cardiac development. Malformations produced by the procedures noted are being investigated by the study of histological preparations of the experimental material and by the study of blood flow through the treated hearts. The effect of these procedures upon partitioning of the heart (septation), valve formation as well as the direct effect of these teratogens on the cardiac tissues is being emphasized. Histochemical analyses (studies of DNA, RNA, polysaccharides and protein synthesis) are also being carried out.

The analyses of the origins of cardiac defects provided by this type of study will aid in our understanding of congenital heart disease in man.

SUPPORTED BY Essex County Heart Assn. - New Jersey

5.0425, METABOLISM AND DOSIMETRY OF 90Y INHALED IN FUSED CLAY PARTICLES BY THE BEAGLE DOG

J.E. BARNES, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

This experiment is part of a long-term study of the biological consequences of inhaling radionuclides such as might be released in certain nuclear accidents. Beagle dogs were exposed once by inhalation to an aerosol of 90Y entrapped in fused clay particles, resulting in initial body burdens of 1,000 to 62,000 muCi. Experimental techniques being used include whole-body counting, scanning, daily collection of urine and feces and serial sacrifices to obtain tissue distribution data. Two groups of dogs have been investigated to date. In the first group consisting of six dogs, sacrifices were made at 0, 2, and 4 days post-exposure. The second group consisted of seven dogs sacrificed at 0, 6, 8, and 12 days post-exposure.

RESULTS: Forty to 60 percent of the initial body burden was excreted rapidly, during the first few days, presumably by mucociliary clearance and swallowing. During the first four days post-exposure essentially all excretion of 90Y was via the feces, indicating the relative insolubility of 90Y in the fused clay vector. Tissue distribution data were obtained by radiochemically analyzing tissue samples following serial sacrifice. After initial clearance most of the 90Y remaining in the dogs was found in the lung, with small amounts in the tracheobronchial lymph nodes, liver and skeleton. Because of the short physical half-life of 90Y (64 hr), practically all of the total radiation dose was delivered during the first two weeks post-exposure. The lung had an initial dose rate of 0.22 rad/min/mCi deposited in lung, and a total cumulative dose of approximately 1200 rads/mCi initial deposit. These data play an important role in the comparison of biological effects to the lung as a function of dose rate, for various inhaled beta emitters.

SUPPORTED BY U.S. Atomic Energy Commission

5.0426, TOXICITY OF 144CE INHALED IN FUSED CLAY BY THE BEAGLE DOG

B.B. BOECKER, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

This experiment is part of a long-term study of the biological consequences of inhaling radionuclides such as might be released from a nuclear accident. Beagle dogs were exposed once by inhalation to Ce144 entrapped in a fused clay aerosol. Sufficient Ce144 activity was present to produce biological damage and lifespan shortening. Clinical, hematological, biochemical and microbiological changes attributable to the radiation insult are being followed throughout their remaining lifespan and pathologic examinations are performed at death. Observed biological effects are related to radiation dose using data from whole- body counting, excreta collections and tissue-distribution studies.

RESULTS: This longevity study involves two series of dogs. Series I with 15 dogs exposed to aerosols of Ce144 in fused clay to yield initial lung burdens of 88 to 2100 muCi and 3 control dogs exposed to non-radioactive clay and Series II with 48 dogs exposed to date to aerosols of Ce144 in fused clay to yield initial lung burdens of 0.10 to 580 muCi and 6 control dogs exposed to non-radioactive clay. The Ce144 in fused clay is retained tenaciously in the lung with only small quantities being translocated to tracheobronchial lymph nodes, liver and skeleton. However, because of the small size of the tracheo-bronchial lymph nodes, they exceed the lung in Ce144 concentration by 100 days post-inhalation. To date, 9 of the 15 dogs in Series I and 5 of the 48 dogs in Series II have died or have been euthanized at 143 to 410 days after inhalation of Ce144. The prominent pathological finding is a severe pulmonary fibrosis. The cumulative radiation dose to the lung to time of death has ranged from 20,000 to 110,000 rads. Serial observations are continuing on all survivors with special attention directed to evaluating various clinical, pulmonary function, hematologic, serum chemical and microbiologic parameters.

SUPPORTED BY U.S. Atomic Energy Commission

5.0427, METABOLISM AND DOSIMETRY OF 90SR INHALED IN FUSED CLAY PARTICLES BY THE BEAGLE DOG

B.B. BOECKER, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

This experiment is part of a long-term study of the biological consequences of inhaling radionuclides such as might be released in certain nuclear accidents. Beagle dogs were exposed once by inhalation to an aerosol of Sr90-90Y, entrapped in fused clay particles, resulting in initial body burdens of 200 to 500 muCi. Experimental techniques being used include whole-body counting, scanning, daily collection of urine and feces and serial sacrifices to obtain tissue distribution data. A preliminary experiment was conducted with nine dogs scheduled for sacrifice in groups of 3 at 8, 256 and 512 days post- exposure. The second experiment, based in part on results from the preliminary experiment, involves 26 dogs scheduled for serial sacrifice in groups of three out to 2048 days post-exposure.

RESULTS: For most of the dogs, from 40 to 60% of the initial body burden was cleared within the first day or two post-exposure; in one dog 84% of the initial body burden was lost. Presumably this initial clearance was the result of mucociliary action, swallowing, and excretion via the gastrointestinal tract. Urine and feces samples collected on selected dogs during the early post-exposure period are currently being analyzed radiochemically. After initial clearance the remaining Sr90 was retained with a long effective half-life of approximately 400 days in the lungs of the dogs in the preliminary experiment. Tissue analyses of dogs sacrificed to date (at 8 and 256 days post-exposure) have shown over 90% of the body burden in the lung and tracheobronchial lymph nodes, the remainder being in skeleton. These data will be an important part of the comparison of biological effects of various beta emitters inhaled in a relatively insoluble form, since they represent a situation in which the total radiation insult is delivered over a period of many years in contrast to shorter-lived radionuclides.

SUPPORTED BY U.S. Atomic Energy Commission

5.0428, TOXICITY OF INHALED 90SR CHLORIDE IN THE BEAGLE DOG

B.B. BOECKER, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

This experiment is part of a long-term study of the biological consequences of inhaling radionuclides such as might be released from a nuclear accident. Beagle dogs were exposed once by inhalation to Sr90Cl2, at levels presumed to produce biological damage and lifespan shortening. Clinical, hematological, biochemical and microbiological changes attributable to the radiation insult are being followed throughout their remaining lifespan, and pathologic examinations are performed at death. Observed biological effects are related to radiation dose using data from whole-body counting, excreta collections and tissue distribution studies.

Forty-eight dogs have been exposed to CsCl aerosols containing Sr90, resulting in initial body burdens ranging from 2.6 to 280 muCi Sr90/kg. These are being maintained for lifetime observation and have been placed in four groups based on their retained Sr90 burden at 14 days post inhalation. Group means were 1.4, 6.2, 30 and 75 muCi/kg.

RESULTS: To date, 24 dogs have died or were euthanized, 6 with severe hematologic dyscrasia, during the first 31 days, and 18 between 585 and 1540 days. The latter group includes 7 with angiosarcomas, 3 with fibrosarcomas, 4 with osteosarcomas, 1 with osteochondrosarcoma, 1 with osteochondrofibrosarcoma, 1 with leukemia, 1 with an epileptic seizure and 1 with cerebellar hemorrhage. (One dog had both an angiosarcoma and an osteosarcoma.) The skeleton of these dogs received initial radiation dose rates of 16 to 60 rad/day and cumulative doses to death of 7500-19000 rads. Serial observations are continuing on the survivors.

SUPPORTED BY U.S. Atomic Energy Commission

5.0429, DISTRIBUTION AND EXCRETION OF 137 CS INHALED IN FUSED CLAY PARTICLES BY THE DOG
B.B. BOECKER, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

This experiment is part of a long-term study of the biological consequences of inhaling fission product radionuclides such as might be released in certain nuclear accidents. Beagle dogs were exposed once by inhalation to an aerosol of Cs137 encapsulated in fused clay particles resulting in initial body burdens of 5 to 130 muCi. Experimental techniques being used include whole-body counting, daily collections of urine and feces and serial sacrifices to obtain tissue distribution data. In a preliminary experiment, three dogs were exposed and sacrificed at 180 days post-exposure. A second experiment, now in progress, involves 30 dogs that are being sacrificed in groups of two at times ranging from immediately to four years post-exposure.

RESULTS: From 30 to 82% of the initial body burden was excreted with the first few days post-exposure, presumably due to clearance of the upper respiratory tract by mucociliary action followed by swallowing and excretion via the feces. The whole-body retention curves for six dogs followed for at least two years post-exposure could be described by 3-component exponential functions whose longest-term component corresponded to an effective half-life of retention that ranged from 350 to 780 days. Tissue distribution data obtained by serial sacrifice during the first two years post-exposure have demonstrated the relatively insoluble nature of Cs137 inhaled in this form. Highest concentrations of Cs137 were observed in lung and tracheobronchial lymph nodes with concentrations in muscle and liver being approximately three orders of magnitude lower. Comparison of these data with similar data for Sr90, Ce144 and Y91 in fused clay should promote a better understanding of the mechanisms of clearance and translocation of these isotopes inhaled in this form.

SUPPORTED BY U.S. Atomic Energy Commission

5.0430, TOXICITY OF INHALED 91Y CHLORIDE IN THE BEAGLE DOG
B.B. BOECKER, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

This experiment is part of a long-term study of the biological consequences of inhaling radionuclides such as might be released from a nuclear accident. Beagle dogs were exposed by inhalation to 91YCl3, at levels presumed to result in biological damage and lifespan shortening. Clinical, hematological, biochemical and microbiological changes attributable to the radiation insult are being followed throughout the lifespan, and pathologic examinations are performed at death. Observed biological effects are related to radiation dose which has been obtained from whole-body counting, excreta collections and tissue-distribution measurements.

Forty-two dogs with 91Y burdens from 73 to 1330 muCi/kg were placed in four groups with mean initial body burdens of 12, 260, 560, and 920 muCi/kg. For comparison with observed biological effects, these same dogs were regrouped on the basis of retained 14-day body burdens, yielding groups with mean values of 31, 59, 140 and 270 muCi/kg. These dogs and 12 control dogs are being maintained for lifetime observation.

RESULTS: Eleven dogs within the highest exposure groups have died or were euthanized at 17 to 33 days after inhalation of 91Y, with changes related to severe bone marrow damage and associated pancytopenia. Two dogs died at approximately one year, with convulsive seizures that were presumed to be unrelated to the 91Y exposure. Thirty-five dogs that had initial body burdens of 73 to 800 muCi/kg and all 12 control dogs are surviving at 800 days or more after inhalation of 91Y. Serial observations are continuing on all surviving dogs.

5.0431, TOXICITY OF INHALED CE144 CHLORIDE TO THE BEAGLE DOG
B.B. BOECKER, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

This experiment is part of a long-term study of the biological consequences of inhaling radionuclides such as might be released from a nuclear accident. Beagle dogs were exposed once by inhalation of Ce144Cl3 at levels presumed to produce biological damage and lifespan shortening. Clinical, hematological, biochemical and microbiological changes attributable to the radiation insult are being followed throughout the remaining lifespan, and pathological examinations are performed at death. Observed biological effects are related to radiation dose as obtained from measurements of whole-body burden, excreta, and tissue-distribution.

Fifty-five dogs that inhaled Ce144Cl3 and 15 control dogs have been placed in a longevity study and will be observed for their lifespan. These dogs have been placed in 6 groups based on initial Ce144 burden (group means 0, 14, 51, 130, 280, and 480 muCi/kg). These were regrouped on the basis of retained Ce144 at 14 days post-inhalation to yield groups with mean Ce144 content of 0, 5.2, 14, 40, 120, and 230 muCi/kg.

RESULTS: Studies on the tissue distribution of inhaled Ce144Cl3 indicate that Ce144 deposited in the lung is translocated at a moderately rapid rate to liver and skeleton. The pattern of distribution is such that significant radiation doses are accumulated to all three tissues. Sixteen dogs from the two highest groups have died; 8 at 21 to 44 days post-inhalation with signs attributed to severe bone marrow damage and associated pancytopenia; 2 at 138 and 144 days with radiation pneumonitis; 3 at 309 to 874 days with hepatic necrosis; 1 at 510 days with marrow aplasia, 1 at 375 days with pulmonary fibrosis, and 1 at 799 days with an osteogenic sarcoma. Serial observations are continuing on the surviving dogs.

5.0432, RADIATION DOSE PATTERNS ASSOCIATED WITH INHALATION OF ALPHA-EMITTING RADIONUCLIDES BY THE BEAGLE DOG
H.A. BOYD, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

Plutonium and the trans-plutonic elements increasingly become potential inhalation hazards as their uses are expanded. To help assess these hazards, we will study inhalation of three widely separated particle sized aerosols of Pu239 (activity median aerodynamic diameter (AMAD) of 0.5 micromillimeter, 1.5 micromillimeter and 3.5 micromillimeter) in the beagle dog, with particular regard to the influence these may have on dose distribution within lung tissue. Translocation from the lung to other organs versus particle size will also be studied. Limited inhalation exposures to the much shorter half- lived Pu238 will be conducted for comparison with the long-lived Pu239, to achieve some estimate of differences in tissue dose rate. In addition, experiments to determine the radiation dose patterns following inhalation of aerosols of two other alpha emitters, Am241 and Cm244, will be carried out with particle size distributions having AMAD's of approximately 1.5 micromillimeter. Results of these studies will be important in interpreting human exposure information associated with the nuclear energy industry, and in more accurately establishing maximum permissible levels for workers and the population-at-large.

RESULTS: At present a pilot inhalation study with Am241 in beagle dogs is in progress. The aerosol behaved as if it were somewhat soluble, with some material leaving the lung to enter primary locations in liver and bone. Body burden measurements are difficult with the low energy gamma emission from this radionuclide (60 keV), but a method has been developed to establish initial burdens by a combination of excreta analyses and whole-body scans. This information is presently accepted for publication in Health Physics. A study with soluble Cm244 is to be started shortly, to quantitate the dosage pattern after inhalation by beagle dogs.

5.0433, CHROMOSOME ABERRATIONS PRODUCED BY INTERNALLY DEPOSITED RADIOACTIVE MATERIALS IN THE CHINESE HAMSTER
A.L. BROOKS, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

As part of the program to evaluate the biological hazards associated with internally deposited radioactive materials, experiments are being conducted on the changes observed in the chromosmes of the Chinese hamster following injection or inhalation of Sr90, Ce144 and Am241. These isotopes were selected because of their presence in nuclear reactors, long effective half-lives in humans and their site of deposition; bone for Sr90, liver and bone for Ce144 and Am241. They also provide a comparison of the effectiveness of protracted beta Sr90 and Ce144 and alpha (Am241) exposures. The characteristic isotopic localization exposes cell types with widely differing turnover rates such as bone marrow cells which have a short cell cycle with a rapid cell turnover and differentiation rate, and liver cells which seldom divide and are fully differentiated. Based on the chromosome changes observed in these organs following Sr90, Ce144 and Am241 exposures, models can be constructed to predict the radiation response of other organs. These experimental systems are being used to evaluate the influence of dose rates and cumulative radiation doses on tissues.

RESULTS: The accumulation of chromosome damage in the bone marrow followig injection with Sr90 is dependent on the radiation dose rate at the time of sacrifice. This is a reflection of the total dose accumulated from one cell division to the next. Cell division acts as a means of cell population repair. Following injection of Ce144 or Am241, the frequency of abnormalities in the liver cells increases with increasing total radiation dose but shows little dose rate effect over the range of rates studied. The slow rate of cellular turnover resulting in a lack of population repair is thought to contribute to this response. Am241 was found to be ten times as effective as Ce144 in producing chromosome aberrations.

5.0434, INITIAL DEPOSITION OF RADIONUCLIDE-CONTAINING PARTICLES IN THE LUNGS OF BEAGLE DOGS

R.G. CUDDIHY, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

Two types of studies have been carried out to determine initial lung deposition patterns. The first utilized La140 labeled aerosols to study the effect that particle size has on localized deposition along the respiratory tract. The aerosols used had activity median aerodynamic diameters (AMAD's) ranging from 0.55 to 2.45 micromillimeters. The deposition patterns were measured in five beagle dogs. The second group of studies involved the autoradiographic localization of inhaled particles along the respiratory tract. Beagle dogs were exposed to aerosols of 90YCl3, 90Y-fused clay, 90Y oxide in ZrO matrix, Ce144-fused clay, La140 oxide and La140-fused clay. They were sacrificed immediately post-exposure, frozen and sectioned longitudinally at the midline. The lungs were also removed. Gross autoradiographs were made of the longitudinal sections and of the lungs, spread flat against the film.

RESULTS: Results of the first group of studies indicated that over the range of particle sizes, mean total body deposition ranged from 30 to 75%, mean pulmonary deposition between 20 and 40%, mean tracheobronchial deposition from 3 to 6% and nasopharyngeal deposition between 5 and 40%. The gross autoradiographic data from the second study also indicated deposition in these areas and, more significantly, a striated pattern along the pleural surface of the lung which resembled the rib formation of the thoracic cage.

5.0435, TOXICITY OF INHALED 90Y IN FUSED CLAY IN THE BEAGLE DOG

C.H. HOBBS, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

This experiment is part of a long-term study of the biological consequences of inhaling radionuclides such as might be released from certain nuclear accidents. Beagle dogs were exposed once to an aerosol of fused clay containing sufficient 90Y to result in biological damage and lifespan shortening. 90Y in fused clay was selected as the aerosol due to its relative insolubility in the lung and its short effective half-life. Clinical, hematological, biochemical and microbiological changes attributable to radiation insult are being followed throughout their remaining lifespan and pathological examinations are performed at death. Observed biological effects are related to radiation dose using data from whole-body counting, linear scans, excreta collections and tissue distribution studies.

RESULTS: At present 51 dogs including 6 control dogs have been exposed to 90Y in fused clay or non-labeled fused clay aerosols. The clinical and pathological findings in these animals can be attributed to radiation damage of the lungs and to a lesser extent, the heart. Principal pathological findings have been pulmonary edema and hemorrhage, fibrosis of alveolar septa, erosion and concurrent regenerative hypertrophy of bronchiolar and alveolar duct epithelium, occlusive pulmonary vasculative lesions, focal adenomatous proliferation of alveolar duct epithelium and myocardial necrosis limited to the right atrium. The remaining dogs with initial lung burdens from 1.0 to 6.7 mCi Y90 are exhibiting no clinical signs at 45 to 200 days post- exposure. A dose-related depression of lymphocytes was the only significant hematological change observed. Terminal biochemical, blood gas and respiratory physiology data have been consistent with respiratory insufficiency. Survivors will be observed for lifespan shortening and the occurrence of radiation-induced neoplasms.

5.0436, TOXICITY OF INHALED 91Y IN FUSED CLAY IN THE BEAGLE DOG

C.H. HOBBS, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

This experiment is part of a long-term study of the biological consequences of inhaling radionuclides such as might be released from certain nuclear accidents. Beagle dogs were exposed once to an aerosol of fused clay containing sufficient 91Y to result in biological damage and lifespan shortening. 91Y in fused clay was selected as the aerosol as an example of an energetic beta-emitter with a short to intermediate effective half-life in the lung. Clinical, hematological, biochemical, physiological and microbiological changes attributable to radiation insult are being followed throughout the dogs remaining lifespan and pathological examinations are performed at death. Observed biological effects are related to radiation dose using data from whole-body counting, linear scans, excreta collections and tissue distribution studies.

RESULTS: At present 32 dogs have been exposed to aerosols of 91Y in fused clay. The initial lung burdens of the dogs range from 100 to 2400 micro curie of 91Y. None of the dogs is exhibiting any detectable abnormalities at times ranging from 10 to 60 days post-exposure. Additional dogs will be exposed to similar aerosols in the future. All the animals will be studied closely as individuals to delineate the biological effects of this type of radiation exposure. It is anticipated that life-span shortening and radiation-induced neoplasms, particularly of lung, will be observed.

5.0437, BIOMEDICAL EFFECTS OF EXPLOSIONS

R.K. JONES, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

The Project is directed toward obtaining an improved understanding of the biomedical effects that result from human exposure to nuclear weapons. The approach is largely analytical in nature and deals with range-yield effects relationships for nuclear explosives and the development of appropriate biomedical criteria needed for assessing hazards and predicting both the number and nature of expected injuries. Revision of such criteria is based on a collection of data from Hiroshima and Nagasaki, full-scale field tests as well as literature surveillance for more recent laboratory data. Although past efforts have dealt with predictive capability for acute injuries as a function of range and yield for human beings exposed in the open, greater emphasis is currently being placed on injuries sustained in various types of protective structures and on more delayed effects.

RESULTS: Staff members participated in the Office of Emergency Preparedness Civil Defense Study resulting in the writing of a document entitled 'A Primer on Biomedical Criteria

for Nuclear Weapons Effects and Their Application to Casualty Prediction Models.' This served as the major biomedical input for this study. Preparations are underway for the revision of the Nuclear Bomb Effects Computer which will serve as a supplement to the revised addition of the Effects of Nuclear Weapons. Initial computational efforts suggest that slant range rather than ground range may be more meaningful in terms of expected effects on people from nuclear detonations.

5.0438, PHYSICO-CHEMICAL NATURE OF 95NB(V) OXALATE IN THE BEAGLE DOG BLOOD AFTER INJECTION OR INHALATION OF 95NB(V) OXALATE

G.M. KANAPILLY, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

The objective of this study is to determine the physico-chemical nature of 95Nb(V) in Beagle dog blood after intravenous or inhalation exposure to 95Nb(V) oxalate. A polyvalent nuclide in blood may combine with (1) cellular fractions, (2) serum proteins, (3) low molecular weight compounds such as citrate and amino acids or (4) inorganic anions. Determination of the physico-chemical nature of 95Nb(V) in blood should provide general information on the behavior of a pentavalent ion in blood and, in conjunction with tissue distribution studies, this information may be used to obtain distribution kinetics data.

Beagle dogs were exposed to 95Nb(V) oxalate via inhalation or intravenous injection. Blood samples were taken from these dogs at various post-exposure intervals and fractionated into cells and serum. The 95Nb(V) activity in each fraction was determined using 'gel permeation chromatography'. The serum samples were fractionated to determine the 95Nb activity in protein fraction and non protein fraction. Dogs were sacrificed at 30 days post-exposure and tissue distribution was determined.

RESULTS: Most of the 95Nb (approximately 95%) has been found to be in the serum and approximately 80% of this fraction was bound to the serum proteins. There has been no difference in the percentage of protein bound 95Nb in the serum of dogs exposed to 95Nb by inhalation or injection. The serum protein binding 95Nb(V) is tentatively identified alpha-globulin. 'In vitro' studies, using 95Nb(V) oxalate and commercial serum proteins, are being performed to determine the formation constants of 95Nb(V) and serum proteins.

5.0439, THE EFFECT OF THE INHALATION OF RADIONUCLIDES IN 'INSOLUBLE' FORMS ON THE FATE OF INHALED BACTERIA IN MICE

D.L. LUNDGREN, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

The objective of this study is to determine what effect the inhalation of radionuclides in relatively insoluble forms will have on the fate of inhaled bacteria in mice. It has been experimentally demonstrated in mice by other investigators that ethyl alcohol intoxication, injection of cortisone, starvation, influenza virus infection, inhalation of tobacco smoke, exposure to hypoxia or cold and acidosis will result in the inhibition of the clearance of bacteria from the lungs of mice. Diffuse silicosis does not inhibit the clearance of bacteria until anatomic lesions become severe. Mice in the present study will be exposed to the inhalation of Ce144, 91Y or 90Y in insoluble forms. At various intervals after the inhalation of the radionuclides mice will be exposed to the inhalation of aerosols of either Staphylococcus aureus, Proteus mirabilis or Streptococcus sp. The fate of the inhaled bacteria in the mice exposed to the inhalation of radionuclides will be compared to the fate of the bacteria in normal mice.

RESULTS: In a series of experimental infection studies recently completed to determine the effect of inhaled Ce144 in fused clay and Ce144O2 particles on the course and final outcome of influenza virus infection in mice little or no effect on the viral infection was observed. However, contamination of lung homogenates with Staphlococcus sp., Streptococcus sp. and Proteus mirabilis and to a lesser extent other bacteria occurred frequently in the mice that had inhaled Ce144 which were subsequently inoculated with influenza virus and to a lesser extent in the normal mice inoculated with virus.

5.0440, RADIATION DOSE PATTERNS FOLLOWING INHALATION OF BETA-EMITTING RADIONUCLIDES

R.O. MCCLELLAN, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

Studies of the radiation dose pattern of inhaled beta-emitting radionuclides is essential to the understanding of the biological effects from internal emitters entering the body via this route. Many studies have been conducted in the past, using the beagle dog, rats, mice, and hamsters. The aerosols inhaled have been both soluble and insoluble forms of many radionuclides of practical importance to the nuclear energy industry, and these have yielded greatly in physical half-life and energy. Thus, the dose rate and the localized total dose patterns have been greatly varied. Future studies utilizing Tm171 oxide, Ru106 tetroxide vapor, Co60, and, Zr95-Nb95 and Sb124 in graded forms of solubility from the oxalate to the oxide, are underway or will be initiated shortly. Both mice and beagle dogs will be utilized in these studies, with emphasis placed upon degree of solubility versus radiation dose pattern. Because the vapor form is of practical importance in high-temperature melt-downs associated with reactor releases, inhalation exposures to this form of aerosol will be emphasized.

RESULTS: Droplets of Zr95-Nb95 have been nebulized from a solution of the chelated oxalate form and have been passed through a heating column maintained at 100 degrees C, 250 degrees C, 600 degrees C, or 1100 degrees C. A group of mice has been exposed to each of the resulting aerosols and the ensuing tissue distribution pattern has indicated a sizeable differential translocation between the Zr95 and the Nb95 at the lower temperatures, but none has been evident at the higher temperatures. Studies on the fate of inhaled Tm171 oxide in the beagle dog have also recently been initiated to study the long-term retention characteristics.

5.0441, METABOLISM AND DOSIMETRY OF Y91 INHALED AS FUSED CLAY PARTICLES BY THE BEAGLE DOG

R.O. MCCLELLAN, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

This study is part of a long-term program to evaluate the biological consequences of inhaling radioactive aerosols such as might be released in certain nuclear accidents. Beagle dogs were exposed once by inhalation to an aerosol of 91Y entrapped in fused clay particles. A total of 30 dogs were exposed. The experimental procedures being used include serial whole-body counting, scanning, collections of urine and feces and serial sacrifices at 0 to 320 days post-exposure to evaluate the tissue distribution. These data are being evaluated to assess the spatial and temporal changes in radiation dose resulting from inhalation of 91Y in a relatively insoluble form. In addition, the data obtained from this continuing study in combination with those of a parallel longevity study (and parallel studies with Y90, Ce144 and Sr90 in fused clay) will aid in assessing the relative importance of variation in the rate of decrease of beta-radiation dose rate of the lung on the resultant biological effects.

RESULTS: In the first few days post-exposure a significant portion of the initial body burden, presumably that fraction deposited in the upper respiratory tract, was excreted in the feces. With time, small amounts of Y91 were translocated to tracheobronchial lymph nodes (presumably in an insoluble form) and to liver and skeleton (presumably in a soluble form).

5.0442, TOXICITY OF SR90 IN FUSED CLAY IN THE BEAGLE DOG

R.O. MCCLELLAN, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

This experiment is part of a long-term study of the biological consequences of inhaling radionuclides such as might be released from certain nuclear accidents. Beagle dogs were exposed once to an aerosol of fused clay containing sufficient Sr90 to result in biological damage and lifespan shortening. Sr90 in fused clay was chosen as the aerosol as an example of an energetic beta emitter with a long effective half- life in the lung. Clinical, hematological, biochemical, physiological and microbiological changes attributable to radiation insult are being followed throughout the dogs remaining lifespan and pathological examinations are performed at death. Observed biological effects are related to radiation dose using data from whole-body counting, linear scans, excreta collections and tissue distribution studies.

RESULTS: At present 12 dogs have been exposed to aerosols of Sr90 in fused clay. At 90 days post-inhalation exposure the 3 dogs with initial lung burdens of from 652 to 676 micro curie Sr 90 are showing clinical signs compatible with early radiation pneumonitis. No deaths have occurred. The remaining 9 dogs with initial lung burdens ranging from 39 to 552 micro curie 90 are showing no clinical signs at this early date. An apparent probably dose-related depression of circulating lymphocytes has been the only significant hematological alteration noted to date. An additional 24 dogs will be exposed to similar aerosols in the near future with further additions at later dates planned. Survivors will be observed for lifespan shortening and the occurrence of radiation-induced neoplasms.

5.0443, THERAPY FOR INHALED RADIONUCLIDES

B.A. MUGGENBURG, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

The removal of radionuclides from the lung and body tissues of aerosol exposed animals is the objective of this research. Inhalation of radionuclides during a nuclear accident is a real hazard. Lavage of the lungs using isotonic saline and other solutions is being examined as to its effectiveness in removing relatively insoluble and soluble beta- gamma emitters and also alpha emitting radionuclides. The medical risk of the lavage procedure itself is being evaluated, particularly in regard to the cardiovascular and pulmonary systems.

Beagle dogs are the experimental animals used in this work. dogs receiving selected radionuclides are given a nose-only aerosol exposure. Following exposure the dogs are lavaged at various times and the effective removal of the radionuclide evaluated. The pathological changes in the lungs and other tissues and the physiological events which occur during and following lavage are being examind to evaluate the medical risks of the lavage procedure itself.

It is anticipated that pulmonary lavage will be a procedure useful in removing inhaled toxic material to prevent disease that would otherwise occur if this material remained in the lung or other body tissues.

RESULTS: Results to date have indicated that a relatively insoluble radionuclide Sr95-Nb95 oxide can be removed in significant quantities up to 32 days post-exposure by the lavage technique. Ce144 given as relatively soluble Ce144Cl3 can be effectively removed up to five days post-exposure. The addition of the chelating agent DTPA, diethylenetriaminepentaacetic acid, to the lavage fluid greatly increases the removal of Ce144 by urinary excretion.

SUPPORTED BY U.S. Atomic Energy Commission

5.0444, LIPID COMPOSITION OF PULMONARY SURFACTANT, EXFOLIATED LINING CELLS AND TISSUE FROM BEAGLE DOGS

R.C. PFLEGER, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

These experiments are part of long-term studies of the biological consequences of inhaled radionuclides on the lungs of beagle dogs. Animals, exposed by inhalation to various radioactive materials and at a sufficient dose level, have developed lung lesions. Radiation effects on the lung tissue, the cells proximate to the alveoli and the surfactant are expected to be manifest in the lipid composition of these lung constituents. If the composition of the lipid components changes from that in normal beagle dog lungs, an altered lipid metabolism would be prime suspect.

RESULTS: The lipids from normal beagle dog lungs, pulmonary surfactant and exfoliated lining cells were quantitated by established procedures. The surfactant and cells were obtained by endobronchial saline lavage. Phospholipids accounted for more than 70% of the surfactant and cell lipids: phosphatidyl choline was the predominant phosphatide. Evidence has been obtained for the presence of phosphatidyl glycerol in beagle dog pulmonary surfactant (10% of phospholipid-P), exfoliated lining cells (7% of phospholipid-P) and lung tissue (3% of phospholipid-P). Cholesterol and its esters accounted for more than 60% of the neutral lipid fractions. Alkyl and alk-1-enyl glycerol ethers were quantitated in the neutral lipids and phospholipids from all samples.

SUPPORTED BY U.S. Atomic Energy Commission

5.0445, BIOCHEMISTRY OF PULMONARY CONNECTIVE TISSUE

J.A. PICKRELL, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

Pulmonary fibrosis has been observed in animals as a consequence of chronic pulmonary irradiation. In an effort to better understand the pathogenesis of pulmonary fibrosis, a quantitative estimation of the major components of connective tissue collagen and elastin is necessary. Lung tissue hydrolysates from normal dogs were prepared and amino acids quantitated by chromatographic elution using a modified Beckman 120B amino acid analyzer and mechanical integration. These methods yielded good resolution and acceptable integration of hydroxyproline and hydroxylysine, relative indicators of collagen, and desmosine, the relative indicator of elastin. The ability to measure these amino acids and thus obtain a quantitative estimation of connective tissue content of normal canine lung lends confidence to the use of this technique for measuring increased quantities of connective tissue associated with pulmonary fibrosis.

Since beta-glucuronidase is a central enzyme in the metabolism of the carbohydrate portion of fibrous connective tissue, a methodology for the measurement of this enzyme was developed for use on lung and other samples.

RESULTS: Measurements are in progress on right cardiac and diaphragmatic lobes of the lungs of these dogs. No meaningful differences between lung lobes have been observed. Twelve, 12-month- old, beagle dogs were exposed to Ce144 fused clay and six control dogs of the same age to the clay vector. The preliminary right apical lung lobe measurements of these dogs revealed no pronounced changes in animals sacrificed at two and four months post-exposure. Animals sacrificed at six months post-exposure had variable responses, two showed some increase of hydroxyproline and to a lesser degree hydroxylysine, suggesting modest collagen elevation, and two showed a slight increase of elastin. Measurements of beta-glucuronidase have been made on the right apical lung lobes of control dogs. Measurements will also be made on lung lobes of the dogs described in the previous study.

5.0446, THE PRODUCTION OF INSOLUBLE AEROSOLS OF FUSED CLAY CARRYING RADIONUCLIDES FOR USE IN INHALATION RESEARCH EXPERIMENTS

O.G. RAABE, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

In order to study the effects of inhalation of insoluble aerosols of fission products, experimental characterization and understanding is simplified through the use of a basic vector (or carrier) aerosol to which the radionuclide of interest has been added. In this study a method of producing insoluble aerosols of fused montmorillonite clay particles in the respirable size range into which both beta-emitting and alpha-emitting nuclides have been entrapped is being developed. This method involves the following basic steps: (1) clay preparation, (2) nuclide ion exchange, (3) aerosolization, (4) heat fusion, and (5) delivery to the inhalation apparatus. Step (1) involves preparing a clean and relatively stable water suspension of the clay. In step (2) the ion exchange properties of clay are used to replace some of the

exchangeable clay ions with ions of the radionuclide of interest. The exchanged clay is washed to remove the unexchanged portion of the nuclide. Step (3) involves aerosolization by atomization of a water suspension by ultrasonics or an air jet atomizer, and (4) the aerosol thus formed is allowed to pass through a heating column and maintained at 1150 degrees C where the clay particles are dried and fused into smooth spheres. In step (5) this aerosol of fused clay microsphere is carried to the aerosol apparatus for inhalation by the experimental animal. The latest efforts in this work are in the production of Y91, Pu239, and other transuranium nuclides aerosols of fused clay.

RESULTS: Aerosols of fused clay have been produced with Y90, Y91, Y88, Sr90-Y, Ce144- Pr144 and Cs137-Ba137 entrapped in the clay microspheres. For a clay suspension of concentration 8 mg/ml, the aerosol produced has a log-normal size distribution with count median diameter approximalty 0.9 mu m and geometric standard deviation approximately 1.8.

5.0447, THEORETICAL DESCRIPTION OF THE INTERACTIONS THAT OCCUR BETWEEN RADON DECAY PRODUCTS AND AEROSOLS

O.G. RAABE, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

The adsorption of radioactive materials to aerosols can be an important consideration for assessing the hazard associated with the inhalation of radioactive materials. The adsorption of radon daughters to aerosols is of particular interest since radon daughters, both attached to aerosols and unattached, represent an important hazard in the mining industry. Since unattached daughters deposit quite differently in the respiratory system than daughters which are attached to aerosol particles, it is important to know the adsorption characteristics and to be able to estimate the fraction of unattached decay products. An initial result of this work was a new attachment principle for the interaction of radon daughters to aerosols which is based upon particle surface area rather than classical diffusion relationships. Under development is an analog model of the interaction of radon daughters with aerosol particles and the walls of a cylindrical containment vessel (or mine drift) to demonstrate the effect of these competing interaction processes.

RESULTS: A new adsorption principle has been developed which predicts that the relative quantity of adsorbed radon daughters on different size aerosol particles is proportional to the surface area of the particles. This is based upon the concept that the Brownian motion of the aerosol particles cannot be ignored even though their diffusion relationships are relatively small, and the diffusion relationships for highly diffusible materials interacting with aerosols only apply for very high interaction rates, much higher than attained with naturally occurring levels of radon. A method of estimating the unattached fraction of each daughter based upon the new adsorption principle was also derived.

5.0448, GENERATION OF MONODISPERSE AEROSOLS OF INSOLUBLE FORMS FOR USE IN INHALATION EXPOSURES

O.G. RAABE, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

Monodisperse aerosols of insoluble forms are needed in inhalation exposures to ascertain the effect of particle size on regional deposition and clearance and upon biological effects of inhaled radionuclides. Three methods of producing monodisperse aerosols are under study. These include: (1) use of the Fulwyler Ultrasonic Droplet Generator, (2) controlled condensation of volatile organic chelates of polyvalent metals, and (3) electrostatic droplet dispersion.

RESULTS: The Fulwyler generator has been used to produce some monodisperse aerosols which are larger than 1 micromillimeter diameter including aerosols of zirconium oxide. Equipment is being assembled for the electrostatic generator system. Preliminary experiments are being conducted with controlled condensation of volatile forms of Co, La, Ce, Zr, and Sb.

5.0449, DOSE-RESPONSE RELATIONSHIPS FOR INHALED ALPHA-EMITTING RADIONUCLIDES

R.G. THOMAS, Lovelace Fdn. for Med. Ed., *Albuquerque, New Mexico* 87108 (AT(29-2)-1013)

A major deficit in our understanding of the effects of inhaled alpha-emitting radionuclides relates to knowledge on the relative importance of number of particles deposited in the lung versus total muCi activity, in producing late effects. Several studies are planned in which beagle dogs will be exposed to aerosols of Pu238, Pu239, and Cm244 as insoluble oxides of different size distributions, achieving groups of dogs with graded levels of initial lung activity. Because of the wide range in specific activity of these radionuclides and with a varied number and size of particles, dogs with similar muCi activity lung burdens in the several studies will have total numbers of particles that vary by a factor of approximately 1000. The exposed dogs will be observed for their total lifespan using clinical, physiological, hematological, biochemical, and microbiological techniques to assess changes in health status that may be attributed to the radiation insult, and pathological examinations at death will be performed in combination with the foregoing procedures to assess the terminal disease state of the dogs. The observed biological effects will be related to radiation dose.

RESULTS: A preliminary study with inhaled Am241 in beagle dogs has indicated primary pathological effects in lung, liver, bone and bone marrow. Procedures for the exposure, long-term care and study of beagle dogs exposed to achieve graded lung burdens of Pu238, Pu239, Am241 and Cm244 when inhaled as oxides are currently being developed and evaluated.

5.0450, THE ROLE OF THYMIC-DEPENDENT LYMPHOCYTES IN THE ACUTE RECOVERY FROM RADIATION INJURY

R.E. ANDERSON, U.S. Veterans Administration, Hospital, *Albuquerque, New Mexico* 87108

Results: As noted in the initial report, we are attempting to define (and influence) the role of thymic-dependent lymphocytes in the early recovery from radiation injury via a series of complementary experiments: progress in the past 12 months may be summarized as follows: 1) Recovery from radiation injury in neonatally thymectomized and/or splenectomized germfree mice - the results suggest that the initial portion of the peculiar biphasic response of the peripheral lymphocyte count to significant amounts of ionizing radiation is splenic-dependent. The rapid disappearance of these cells suggests that they are transients in the peripheral circulation and subsequently home to other lymphoreticular tissues. Although recovery of the peripheral lymphoid pool is somewhat sluggish in the absence of the spleen, restoration is possible in the absence of this considerable portion of the lymphoreticular system. 2) Effects of antilymphocyte serum in neonatally thymectomized mice - this study was undertaken to gain familiarity with antilymphoycyte serum - the results suggest that, in contradistinction to adult mice, the consequences of ALS administration to newborns are but slowly reversible and complete recovery may not be possible in the absence of the thymus. 3) Lymphoid regeneration following exposure to ionizing radiation and/or antilymphocyte serum - this portion of the study is in progress and is designed to compare immunologic recovery from ALS administration vs. irradiation in intact and thymectomized mice. 4) Restoration of thymic- dependent lymphocytes following exposure to 400 rad of ionizing radiation - this series of experiments is as yet in progress but preliminary results on day 14 post-exposure indicate a considerable discrepancy between recovery of the peripheral lymphocyte count vs. the production of thoracic duct (thymic dependent) lymphocytes, particularly in the absence of the thymus.

5.0451, THE PATHOLOGY OF ACCELERATED AGING IN GERMFREE MICE
R.E. ANDERSON, Univ. of New Mexico, School of Medicine, *Albuquerque, New Mexico* 87106

The purpose of this project is to investigate the contribution of bacterial and viral infections and symbiotic presence to the evolution of the late effects of ionizing radiation in mice. It is specifically aimed to determine whether or not apparent and inapparent infections are related to the decreased longevity associated with the post-irradiation state. There is suggestive evidence that the presence of bacteria and/or viruses may greatly modify the direct effects of the physical agent; if the life-shortening effect of radiation of equal dose is significantly diminished in germfree as compared with conventional laboratory animals, such would constitute strong evidence that radiation does not, in fact, induce an acceleration of physiologic aging.

5.0452, COMMUNICATIONS - NUCLEAR RADIATION EFFECTS ON ELECTRONIC COMPONENT MATERIALS AND ELECTRONIC DEVICES
W.W. GRANNEMANN, Univ. of New Mexico, School of Engineering, *Albuquerque, New Mexico* 87106 (N00014-68-A-0158)

Technical Objective: This research is directly related to the support of Navy communication and surveillance systems incorporating electronic materials and devices which are vulnerable to nuclear radiation. There is a continuing need for materials and devices with greater resistance to radiation effects and also a need for understanding such effects in order to predict how devices will react in a radiation environment.

SUPPORTED BY U.S. Dept. of Defense - Navy

5.0453, MACROMOLECULAR RADIATION PATHOLOGY
S.W. JORDAN, Univ. of New Mexico, School of Medicine, *Albuquerque, New Mexico* 87106

A study is being made of the fine structural and macromolecular changes induced in a variety of cells by ionizing radiation. The changes to be investigated are those which occur directly as a result of irradiation or appear within a few minutes.

It is planned to use a wide range of dosage and modalities of ionizing radiation, concentrating especially on gamma ray doses between 100 and 1000 rads, especially with regard to nuclear effects, but also investigating the effect of massive irradiation on the order of 10 to the 4th power to 10 to the 6th power rads, delivered by a flash X-ray source.

Radiation damage to DNA molecules is being investigated by isolating DNA in thin protein films and visualization by electron microscopy (Kleinschmidt procedure).

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0454, BASIC EFFECTS OF MICROWAVES ON BIOCHEMICAL PROCESSES
A. VANHEUVELEN, New Mexico State University, School of Arts, *Las Cruces, New Mexico* 88001

Electron paramagnetic resonance (EPR) and visible and near ultraviolet band spectra measurements will be used to monitor changes in biochemical processes caused by microwave radiation. The purpose of these studies is to determine if there are non-thermal effects of microwaves on biochemical processes. If non-thermal effects are found to exist, then it should be possible to determine: (i) the molecular basis for these effects (such as steric distortions of enzymes, mutations, polarization of dipolar molecules which are interacting, localized heating of enzymes.); (ii) the dependence of these effects on the intensity of the microwave radiation; and (iii) the dependence of these effects on the frequency of the microwave radiation. This information should be helpful in evaluating the value of present microwave dosimetry standards.

5.0455, TRANSFORMATION AND RECOVERY OF HAEMOPHILUS INFLUENZAE FROM ULTRAVIOLET AND X-IRRADIATION DAMAGE
B.J. BARNHART, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

An ultraviolet (u.v.)-sensitive (BC100) and an u.v.-resistant (BC200) mutant have been isolated from the transformable bacterium Haemophilus influenzae strain Rd. These mutants will be used to determine if there is a dependence of DNA replication and integration of transforming DNA on repair of photoproducts in the DNA. Alkaline sucrose gradients will be used to determine single-strand breaks, and a two-dimensional paper chromatographic isolation of u.v. photoproducts (pyrimidine dimers) will be used to follow actual excision of the photoproducts. DNA synthesis will be followed by incorporation of 3H- thymidine into the nucleic acid of irradiated cells. Integration of transforming 3H-DNA into 32P-labeled recipient cells will be determined by double-label counting of DNA fractions from a neutral sucrose gradient. Fractions representing both integrated and nonintegrated DNA will be assayed for single-strand breaks and pyrimidine dimers.

Results: The difference in abilities to reactivate u.v. damage is displayed by varying colony-forming abilities, host-cell reactivation of irradiated phage, and competent-cell reactivation of irradiated transforming DNA. BC100 lacks these reactivation capabilities, while Rd and BC200 have equal capabilities. BC200 has an enhanced survival because it lacks the post-irradiation lytic response characteristic of the parental strain, Rd. Post-u.v. filament formation previously observed for BC200 is also characteristic of BC100 and Rd, but filaments of the latter two strains exhibit cell lysis while BC200 does not. Results indicate that the lytic response of the wild type, Rd, is the result of derepression of a defective prophage which codes for the synthesis of a lytic enzyme.

5.0456, TRANSFORMATION AND RECOVERY OF HAEMOPHILUS INFLUENZAE FROM ULTRAVIOLETAND X-IRRADIATION DAMAGE
B.J. BARNHART, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

Ultraviolet- (uv) sensitive and uv-resistant mutants of the transformable bacterium Haemophilus influenzae strain Rd are being used to determine the effect of uv-light on cell survival and on replication and recombination of DNA. Survival of bacteria following uv irradiation is largely dependent on DNA-repair processes, but other debilitating effects of radiation are frequently not considered to be significant factors leading to loss of cell viability. DNA-repair by the excision- repair process is monitored by detecting single-strand breaks in the backbone of the DNA double-helix in alkaline sucrose gradients and subsequent solubilization of uv-photoproducts (pyrimidine dimers) by quantitating DNA dimers using two-dimensional paper chromatography. DNA synthesis is followed both by incorporation of tritium-labeled thymidine into the nucleic acid of irradiated cells and by total DNA mass increase using the Burton diphenylamine reagent. The effect of uv on DNA recombinational events will be determined by assaying integration of irradiated transforming DNA into irradiated and unirradiated cells.

Results: Effects of uv light on cell morphology, DNA synthesis, and protein synthesis in uv-sensitive and uv-resistant mutants of H. influenzae strain Rd have been examined. Low doses of uv do not stop DNA synthesis in any strains but do slow the synthesis rate in a manner consistent with the model correlating the kinetics of post-uv DNA synthesis with the cell's ability to repair uv-induced DNA damage. Relatively low doses of uv induce lysis of the sensitive mutants and w- plus but not of the resistant mutant.

5.0457. IN VIVO MEASUREMENT OF PLUTONIUM LUNG BURDENS IN HUMANS

P.N. DEAN, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

Evaluation of the lung burden of plutonium in chronically exposed plutonium process operators is needed for proper industrial medical control of this material. Urinary and fecal assays for plutonium are unreliable and primarily a measure of the systemic burden. Three types of detectors are presently being investigated for the in vivo measurement of plutonium in the lung. Several proportional counters have been constructed. The latest version consists of two 7 x 12 x 5- in. thick chambers utilizing internal anticoincidence sections for maximum background reduction. Inorganic crystal detectors consisting of thin crystals optically coupled to thick ones have been procured and are undergoing testing. By making the thin crystal of CsI (Tl) and the thick crystal of NaI (Tl), the difference in decay times of the two scintillators can be used in an anticoincidence arrangement to count only those events that occur in the thin crystal. This results in much lower backgrounds than can be obtained with single thin crystals. A large surface area (12 cm squared) Ge (Li) solid state detector has also been obtained for investigation of its possible application in this field.

Results: Calibration of the dual-crystal counter has been completed and routine counting of plutonium workers begun. As of May 1970, 200 workers have been counted: 16 had an average of 5 nCi plutonium-239, 13 an average of 1.4 nCi plutonium-238, and 12 an average of 0.22 nCi americium-241. The highest burdens measured were 16 nCi plutonium-239, 20 nCi plutonium-238, and 1.62 nCi americium-241. The minimum detectable amount is believed to be about 3 nCi plutonium-239 and 1 nCi plutonium-238. Developmental studies of the proportional counter have been stopped. Tests of the solid state detector are proceeding.

5.0458. GENETIC EFFECTS OF X-RAY EXPOSURE ON REPRODUCTION

J.F. DPALDING, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

If radiation-induced mutations resulting from exposure to consecutive generations of male progenitors are minor, heritable, and cumulative, they should result in population shifts in reproductive characteristics. Reproductive and litter characteristics are under investigation on progeny pairs of mice from 45 generations of x irradiated male progenitors. Comparative studies on irradiated and control lines should be completed this fiscal year and will terminate this program.

Results: Reproductive and litter characteristics data on progeny from X-irradiated male progenitors with 40 generations of exposure have been compiled but have not been analyzed at this time.

SUPPORTED BY U.S. Atomic Energy Commission

5.0459. COMPARATIVE METABOLISM OF RADIONUCLIDES BY MAMMALS - FACTORS WHICH ALTER NORMAL METABOLIC PARAMETERS

J.E. FURCHNER, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

One phase of metabolic studies is an attempt to alter the rate of radionuclide excretion. Factors such as diet, radiation, aging, ambient temperatures, water intake, physical activity, hormones, and complexing agents have been studied. In addition to being of practical importance to the field of radiation protection, these studies add to our knowledge of metabolism, nutrition, and excretion of specific radionuclides. Rodents, beagles, and monkeys are used in these studies. Whole-body measurements of radioactivity are made by means of large-volume liquid scintillation counters and, in some instances, by gamma-ray spectrometry using NaI (Tl) crystals.

Results: Beagle bitches with a cesium-137 body burden monitored before, during and after pregnancy showed an increased rate of cesium- 137 loss during pregnancy and a further increase in the rate of loss after delivery while suckling the litter. In the case of mice maintained on drinking water contaminated with cesium-137 and a synthetic diet, a 50 percent substitution of alfalfa for casein caused an increase by a factor of about 1.5 in equilibrium body burden compared to controls maintained on coventional synthetic and commercial diets.

5.0460. TISSUE REACTION TO DISCRETE, HIGH SPECIFIC-ACTIVITY PARTICULATES, WITH EMPHASIS ON TUMOR FORMATION IN THE LUNG

L.M. HOLLAND, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

It is proposed to study the rate of pulmonary tumor production from discrete particulate sources of plutonium isotopes lodged via intravenous injection in the lung capillary bed of hamsters and rats. In addition, attempts will be made to determine the probability of radiation-induced malignant transformation in vitro using primary tissue explant cultures. Results of both types of studies will be used in an effort to construct a computer model for evaluating tumorigenic risk to the public domain from exposure to high specific activity particulates (with emphasis on oxides of the plutonium isotopes) released accidentally to environment.

Results: The required techniques both for the whole-animal and cellular studies have been developed. A preliminary computer code has been written and generally applied to evaluation of probability of tumor formation as a function of number of particles, particle activity (dose per particle), and volume of tissue at risk.

5.0461. INFLUENCE OF HIGH LET RADIATIONS ON DIVISION DELAY AND SURVIVAL OF MAMMALIAN CELLS IN VITRO

D.F. PETERSEN, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

Cycle-dependent duration of division delay and survival of a variety of established mammalian cell lines exposed to radiations of differing LET are being systematically investigated employing methods for synchrony induction and life-cycle analysis previously developed in this laboratory. The studies are preliminary to the eventual comparisons of negative pions with other high LET radiations and evaluation of therapeutic regimens designed to take advantage of precise energy deposition, potential age-dependent enhancement of radiosensitivity, and reduction of the effect of hypoxia on survival.

Results: The effects of 2-Mev neutrons, cobalt gamma rays, and 250-KVP X rays on division delay are qualitatively similar in terms of onset and recovery kinetics, but the delay per rad following exposure to 2-Mev neutrons is 3 times that observed after X-ray or gamma irradiation.

5.0462. FALLOUT CESIUM-137 IN A NORMAL POPULATION

C.R. RICHMOND, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

Since 1956, a group of normal subjects has been monitored on a weekly (12 subjects) or a monthly (42 subjects) basis to determine whole- body burdens of fallout cesium-137. Estimates of the radiation dose due to inadvertent ingestion of fallout cesium-137 are made from these data. Models of the relation between body burden and contamination levels of food are tested with these data, as well as models describing the change of activity as a function of time in a normal population. A large- volume liquid scintillation counter with near 4 pi geometry is used to make the necessary whole-body radioactivity determinations. The presence of activities other than that of fallout cesium-137 and natural potassium-40 is monitored by periodic assay of subjects in a gamma-ray spectrometer.

Results: A data summary has been published. Models describing cesium137 activity in a normal population as parent-daughter growth and decay fit the activity in a normal population since the 1964 peak period. Dietary contamination data can be used to estimate population burdens, which are now decreasing ever more slowly.

5.0463, BIOLOGICAL RESPONSES TO RADIOFREQUENCY RADIATION
J.F. SPALDING, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

Present standards for exposure to radiofrequency or microwaves are set at 10 milliwatts/cm2. There is no evidence in the free world to indicate that this standard should be lowered; however, Russian reports claim effects at lower exposure levels. Essentially no biological information exists at the 200- and 800-MHz levels, which are the two frequencies to be used in the production of pi mesons. These two frequency levels will be investigated for possible biological effects in mice.

5.0464, GENETIC EFFECTS OF X-RAY EXPOSURE ON LONGEVITY
J.F. SPALDING, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

The mutagenic nature of ionizing radiations and the effects and heritability of these mutations are subjects of general concern and interest, as evidenced by periodic press releases propounding new statistical evidence of the lasting effects of radiation from fallout on certain population segments. The genetic effects of progenitor X- ray exposure on longevity of their nonirradiated progeny are under investigation on mice with 40 and 45 generations of X-ray exposure to their male progenitors. Radiation-induced mutations, if heritable, should accumulate until such time as they result in an increase in incidence of diseases causing early death.

Results: Comparative investigations of growth and mortality rates in controls and mice with up to 35 generations of progenitor X irradiation failed to reveal radiation-induced and heritable genetic injury.

5.0465, RADIATION INJURY AND RECOVERY IN DOGS AND PRIMATES
J.F. SPALDING, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

Dose-rate effects studies in the medium to low dose-rate range (1 to 5 rads/hour) in dogs and primates are wanting and are essential to the establishment of acceptable levels of radiation exposure in emergency situation. Rhesus monkeys of both sexes and with different histories of gamma-ray exposure (0 to 1000 rads) are being studied to determine the repair rates, residual or irreparable injury, and total accumulated doses which may be feasible when the fractionation method and appropriate repair intervals are used.

Results: Investigations completed on dogs and monkeys to date indicate that the repair rate of the monkey is somewhat longer than the RT 50 of 28 days proposed for man.

SUPPORTED BY U.S. Atomic Energy Commission

5.0466, GENETIC INVOLVEMENT IN RADIATION SENSITIVITY
J.F. SPALDING, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

The degree to which radiation resistance is genetically controlled in the various tissues and organs of the mammal has been the subject of much research. Two substrains of mice from one highly inbred RFM strain have been developed which have different radiation-resistance characteristics. Investigations are in progress to attempt a determination of the number of gene loci involved in this radiation- resistance factor and the primary organ involved in the radiation resistance difference between the two substrains.

Results: Two substrain populations of different radiation sensitivities have been developed. The resistance factor has been shown to involve primarily the hematopoietic tissues. Evidence to date indicates that a single gene locus may be responsible for the radio- resistance difference.

5.0467, THE RELATIONSHIP BETWEEN RADIATION SENSITIVITY AND OTHER PHYSICAL AND PHYSIOLOGICAL CHARACTERISTICS WITHIN ONE STRAIN OF MICE
J.F. SPALDING, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

A major factor in understanding injury and repair kinetics of radiation exposure is the genetic nature and relationship between radiation and characteristics such as activity, life span, body weight, etc. A number of characteristics are now being investigated in two sublines of strain RFM mice with different radiation-resistance factors. Currently under investigation are reproductive characteristics and life span.

Results: An inverse relationship between radioresistance and activity has been demonstrated in two sublines of RFM mice with different radiation-resistance characteristics.

SUPPORTED BY U.S. Atomic Energy Commission

5.0468, DOSE-RESPONSE AND RECOVERY KINETICS FROM LOW-INTENSITY CONTINUOUS AND SUBLETHAL ACUTE GAMMA-RAY EXPOSURES WITH DOGS AND PRIMATES
J.F. SPALDING, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

Where dose-response data are available on the primate, they are largely at the acute lethal dose level or for exposures of short duration. Relatively few, if any, comparative dose-effect studies with dogs and primates have been reported where the comparisons were made simultaneously under the same exposure conditions. An on-going primate study is being done to test the resilience of bone marrow subjected to 100-rad gamma-ray exposures at 56-day intervals. Comparative dose- response and recovery investigations will be done with dogs and monkeys this fiscal year. The bone marrow will be the organ of primary interest. Thus, dose rates and/or fractions will be such that other vital organs will be affected to a lesser degree.

Results: Rhesus monkeys of both sexes have completed a 560-day fractionated gamma-ray exposure schedule designed to investigate residual effects and recovery capability of primate hematopoietic tissue. Four groups of monkeys with total gamma-ray doses of either 1000, 1500, 1750, or 2000 rads have demonstrated remarkable recovery capabilities when an optimum exposure and recovery time discipline is afforded to them.

SUPPORTED BY U.S. Atomic Energy Commission

5.0469, GENETIC EFFECTS OF PROGENITOR X-RAY EXPOSURE ON REPRODUCTION AND DEVELOPMENT IN PROGENY
J.F. SPALDING, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

Recent statistical studies have been used to demonstrate a direct relationship between radioactivity in or near mammalian germ cells and infant mortality and birth weight. An investigation to study the possible accumulation of radiation-induced genetic injury has been on- going for over ten years. Among end points being observed are reproductive fitness and progeny characteristics through weaning age. This program was formally terminated with the 45th generation. Data on the 45th generation are now being evaluated.

Results: Evaluation of comparative data on earlier generations was of a negative nature, resulting in disinterest and discontinuation of the program.

5. RADIATION

SUPPORTED BY U.S. Atomic Energy Commission

5.0470, GENETIC EFFECTS OF X-RAY EXPOSURE ON LONGEVITY
J.F. SPALDING, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

Longevity has been thought to be a useful end point as a measure of radiation-induced genetic injury in terms of an accumulation of minor mutations which eventually cause a reduction in life expectancy through an increase in the rate of killing diseases. An early report recorded by the United Nations Scientific Committee on the Effects of Atomic Radiation (1962) stated that longevity was inversely related to the total body dose of neutron exposure to the sire. Subsequent studies with genetic exposures of X and gamma rays and neutrons have not been able to confirm this early finding. Progeny mice from 45 generations of X- irradiated male progenitors (200 rads per generation) are under investigation to determine the validity of the life shortening effect hypothesis.

Results: Life span studies have been completed on progeny mice from male progenitors with 5, 10, 15, 20, 25, 30, 35, and 40 generations of X irradiation (200 rads per male progenitor per generation). No reduction in life span of mice from irradiated parentage has been observed.

SUPPORTED BY U.S. Atomic Energy Commission

5.0471, LOW-INTENSITY GAMMA-RAY EFFECTS AND RESPONSE CAPABILITY OF MOUSE BONE MARROW
J.F. SPALDING, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

Past experience has demonstrated that, if the exposure dose rate of cobalt-60 gamma rays is selected properly, hematopoiesis can be blocked with a minimum of injury or effect to other vital body tissues and organs. Mice will be used in an investigation to (a) determine the optimum dose rate for selective bone marrow arrest, (b) compare the effects of equal total doses of gamma rays administered continuously at a low dose rate or fractionated at a higher dose rate (within the same time scale) on hematopoiesis, survival time, and cause of death (incidence of myeloid leukemia, etc.), and (c) estimate the 'so-called' irreparable injury component as it may be related to recovery rate of the hematopoietic tissue and accumulated gamma-ray dose.

Results: Studies have been done to establish optimum dose rate and recovery time exposure regimes. However, the results of these earlier studies were complicated by Pseudomonas infection in the mice under investigation. This problem has been remedied.

SUPPORTED BY U.S. Atomic Energy Commission

5.0472, RADIATION-INDUCED DIVISION DELAY AND RECOVERY
R.A. WALTERS, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

Investigation of biochemical events associated with radiation- induced division delay and recovery is being continued in mammalian cells. Methods for synchrony induction and life-cycle analysis have been used to establish a terminal point of action of X rays in the life cycle coincident with the end of protein synthesis essential for division. These studies have been expanded to determine the relative distribution of cells in the life cycle after irradiation and the response of specific segments of the population to such radiation.

Results: In CHO cells, the duration of division delay is constant regardless of cycle position, and recovery requires protein but not DNA or RNA synthesis. Cells must be metabolically active to recover; conditions which enhance survival (e.g., incubation at 5 degrees C) prevent repair of the delay defect. DNA replication is completed at a dose-independent rate faster than recovery of division capability, indicating a lack of obligate coincidence between DNA replication and other events essential for division.

SUPPORTED BY U.S. Atomic Energy Commission

5.0473, PLACENTAL PROGESTERONE SYNTHESIS FEEDBACK CONTROL AND RADIATION SENSITIVITY
M. WIENERKENNEDY, Union College & University, School of Medicine, *Albany, New York* 12208 (AT(30-1)-3899)

Steroid synthesizing enzymes (delta5-3beta-hydroxysteroid dehydrogenase, 20 alpha-reductase and the series of enzymes which cleave the side chain of cholesterol) are being used as systems in which to observe the effects of X-irradiation on the placenta. The placenta is known to be radioresistant and progesterone, a steroid hormone which is synthesized via these enzymes, is believed to be essential for the maintenance of pregnancy. Human placentas are obtained at Caesarian section or therapeutic abortion. In vitro kinetic studies are performed on the above enzymes, using subcellular fractions of the placenta and various steroid substrates. Placental steroid metabolites are tested for possible feedback inhibition of the reactions. Similar studies are performed after the administration of X-irradiation, and the results compared with the unirradiated tissues in order to define more precisely the effects of irradiation.

Studies of a similar nature are planned on abnormal placentas and those from spontaneous abortions.

Results to Date: The radioresistance of the placenta has been confirmed in the above systems. Low levels of X-irradiation cause an apparent stimulation of enzymatic activity. Evidence has been found for a possible natural inhibitor which will be investigated for radiosensitivity.

5.0474, RNA SYNTHESIS IN MAMMALIAN CELLS AFTER RADIATION
R.E. BASES, Yeshiva University, School of Medicine, *Bronx, New York* 10461

Abstract: Ribosomal RNA synthesis in HeLa cells is depressed 30 to 50% immediately after 1000 rad; the rate of synthesis returns to normal or nearly normal levels within 24 hours.

The influence of radiation dose on depression of ribosomal RNA synthesis and the schedule of its recovery will be studied in detail. The quality of ribosomal RNA synthesized in irradiated cells will be tested by a) studying the participation of ribosomes from these cells in polypeptide synthesis in vitro and b) by studying the ability of their ribosomal RNA to hybridize with DNA from control and irradiated cells using the technique of competition hybridization with presaturation of HeLa DNA using appropriate RNA. Inhibition of post radiation repair by lucanthone will be correlated with the drug's action as an inhibitor of ribosomal RNA synthesis in HeLa cells. Combined treatment of an experimental mouse neoplasm by radiation and lucanthone will be studied in order to judge its possible future usefulness as an adjuvant in radiation therapy of human neoplasms, especially because lucanthone is a safe drug widely used for many years in man as a schistosomicide.

5.0476, A GENETIC, CYTOLOGICAL AND BIOCHEMICAL STUDY OF CELL CYCLE DEPENDENT CHANGES IN RADIATION SENSITIVITY IN YEAST
C.A. BEAM, City University of New York, School of Liberal Arts, *Brooklyn, New York* 11210 (AT(30-1)3998)

Coincident with the onset of budding, yeast cells display an anomalous increase in radiation resistance. It is not known whether this resistance is caused by protection against damage or repair of damage. Radiosensitive mutants have been isolated, and sensitive budding cells can also be produced by various physiological manipulations. The change from the sensitive to the resistant condition is being studied using cytochemical and ultrastructural analysis, and the molecular weight distribution of DNA from cells in various sensitivity states before and after irradiation is being determined.

Results: The radiosensitive mutants have been mapped, characterized, and shown to vary in their capacity for one kind of repair. Cytochemical studies show some differences between sensitive and resistant stages. Early ultracentrifuge CsCl runs seem promising.

5.0477, INVESTIGATION OF THE EFFECT OF TOPICAL CORTICOSTEROIDS ON THE APPEARANCE AND SEVERITY OF ACUTE RADIODERMATITIS

Y.L. LYNFIELD, U.S. Veterans Administration, Hospital, *Brooklyn, New York* 11209

On comparing aquaphor with 1% hydrocortisone in aquaphor ointment on 3 patients (5 portals), we found that the intensity of radiodermatitis showed no difference on 1 portal, aquaphor more intense than hydrocortisone ointment on 1, hydrocortisone ointment more intense than aquaphor on 3. However, the intensity of radiodermatitis on all 5 portals was greater than expected for the dose given, and we became suspicious that applying any grease early in radiotherapy might increase the intensity of the skin reaction.

Therefore, on 5 portals, aquaphor application was compared with no application. One showed slightly more reaction with aquaphor; 4 showed no difference.

Then, on 13 portals, 1% hydrocortisone in aquaphor was compared with no application. Reaction was equal on 9; less in the area treated with hydrocortisone on 4.

Having demonstrated that the application of 1% hydrocortisone in aquaphor applied immediately after each treatment does not increase the intensity of radiodermatitis; we now plan to retest the aquaphor alone and then return to our original protocol, comparing the two ointments with each other. This will probably take 2 more years.

SUPPORTED BY U.S. Veterans Administration

5.0478, RADIATION RESPONSE OF BACTERIAL RADIATION REPAIR SYSTEMS

A.K. BRUCE, State University of New York, School of Arts, *Buffalo, New York* 14222 (AT(30-1)-4171)

The initial damage brought about by radiations is approximately equal in all bacteria. The wide range observed in radiosensitivity is dependent upon the function of repair systems to convert potentially lethal damage to a viable state. While the damage caused by ionizing and ultraviolet radiations is qualitatively different, its repair appears to proceed in part through common pathways. This study will test the hypothesis that lethality results from radiation-induced damage to one or more components of the repair system. Measurements of the X- ray sensitivity of the pyrimidine dimer excision enzyme associated with repair of UV damage will be made. The systems will include whole cells (Escherichia coli and Micrococcus radiodurans), transforming DNA-M. radiodurans and T7-E. coli. The rate of dimer removal from cells, transforming DNA or phage will be assayed in control and X-irradiated cells. Repair and/or resynthesis of the repair enzyme will be studied by incubation of irradiated cells prior to presentation of the dimer- containing substrate. The possible role of endogenous sulfhydryl levels in the protection against ionizing radiation damage will be considered.

Results: Experimental procedures for the uptake of H3-thymidine by M. radiodurans, sucrose density gradient analysis of DNA, transformation of M. radiodurans, preparation of H3-transforming DNA, incorporation of H3-DNA, and dimer production and assay by paper and column chromatography have been developed and tested. The results indicate that the proposed experimental techniques necessary to carry out this project are both appropriate and adequate to yield the desired information.

5.0479, CELL KINETICS OF IRRADIATED SKIN

J.O. ARCHAMBEAU, Meadowbrook Med. Ed. Res. Fdn., *East Meadow, New York* 11554

The objective of this research is to quantify the changes produced by irradiation on the skin of swine. Earlier work has defined the evolution, time course and dose dependence of the moist reaction produced by increasing exposures. Current work has measured the changes in the prickle and basal cell population following increasing exposures. The basal (proliferative) cell changes show essentially an increase in cells immediately following irradiation, followed by a progressive decrease to a minimum value. This minimum value is dose dependent. If regeneration occurs, it is first documented at 17 to 21 days by finding islands of proliferative cells that increase in size over subsequent days. The rate of regeneration is dose dependent, as well as the time that regeneration is completed. The mitotic index varies following irradiation from a low of zero to high values in the regenerative islands of about 16 per cent. The tritiated thymidine labeling index varies from control levels to highs of 40 to 70 per cent.

The number of regenerating islands is dose dependent and a dose survival curve with a D sub zero of 354 rads has been established.

Ongoing work is determining cell parameters of the capillary epithelium prior to irradiation.

5.0480, PHASE I. FISSION PRODUCT METABOLISM AND RESPONSE IN LABORATORY AND DOMESTIC ANIMALS: RADIATION EFFECTS ON REPRODUCTION AND EMBRYOGENESIS

C.L. COMAR, State University of New York, School of Veterinary Medicine, *Ithaca, New York* 14850 (AT(30-1))

A technique has been successfully established in our laboratory for the 'in vitro' culture of preimplantation mouse embryos. This technique is to be used to study: (a) implantation capability of irradiated embryos, (b) uptake of selected radionuclides by embryos, (c) preimplantation effect from paternally administered radionuclides, (d) effect of radiation-induced chromosome-breaking factors on embryo development.

Results: Radiation effects on embryos have been shown as follows: (a) The LD50 values, as measured by development to blastocyst, are approximately as follows: one-cell (3 hrs. post coitus), 90 rads: one- cell (13 hrs. post coitus), 160 rads; two-cell, 400 rads; four-cell, 500 rads; and morula, 300 rads. (b) There is little, if any, difference in radiation response between embryos irradiated or grown in vivo and 'in vitro'. (c) Morphologic abnormalities produced by radiation of embryos include fragmentation, disintegration, incomplete cleavage and cytoplasmic granulation. (d) Cleavage delay is produced by doses between 50 and 300 rads. Part 1 of 7.

5.0481, PHASE I FISSION PRODUCT METABOLISM AND RESPONSE IN LABORATORY AND DOMESTIC ANIMALS - SOME ASPECTS OF STRONTIUM METABOLISM

C.L. COMAR, State University of New York, School of Veterinary Medicine, *Ithaca, New York* 14850 (AT(30-1))

Prediction equations have been developed in this laboratory for the estimation of 90Sr body burdens at some given time based on the known burden at some previously time and the 90Sr/Ca ratio of the diet during the given period. These equations will be checked by controlled observations on pigs and rats at different ages. Human survey data will be used to test the degree of fit to the equations. These equations may provide information about the rate of skeletal strontium turnover and the Sr/Ca discrimination as a function of age.

A study is in progress to relate site of radiostrontium deposition with the degree of radionuclide concentration. More data is

needed to extend the time curves to get better estimates of the integrated radiation dosages. In addition to specific bone concentrations whole body counts will be made so further data for retention equations will be forthcoming.

Results to date: A prediction equation for 90Sr in the human population has been developed which takes into account the Ca and 90Sr balance; Sr/Ca discrimination; 90Sr balance; Sr/Ca discrimination; 90Sr turnover in bone; reutilization of 90Sr liberated from bone. Studies of 85Sr deposition have shown that teeth and ear bones both show high deposition of radiostrontium and high retentiveness. The correlation between such behavior and the site of incidence of strontium-induced bone tumors is high. Part 5 of 11.

5.0483, PHASE III - FISSION PRODUCT METABOLISM AND RESPONSE IN LABORATORY AND DOMESTIC ANIMALS - NEURAL AND BEHAVIORAL ASPECTS OF RADIATION
D.N. TAPPER, State University of New York, School of Veterinary Medicine, *Ithaca, New York* 14850 (AT(30-1))

Based on known neural and behavioral response to ionizing radiation three areas of work are planned: (a) behavioral assay of radioprotective agents in the rat and exploration of mechanisms of radioprotection (b) physiological studies in the rat of performance decrement following massive radiation doses and (c) effects of radiation on labile states of the spinal cord of the cat.

Results: It has been established that a protective agent can reduce the effectiveness of X-radiation in causing conditioned aversion behavior. The mechanisms and early reaction (within milliseconds) to taste stimuli have been explored. Techniques have been worked out for measurement of labile states of the spinal cord. Part 2 of 7.

5.0486, RBE OF MONOENERGETIC NEUTRONS
H.H. ROSSI, Columbia University, School of Medicine, *New York, New York* 10032

The immediate research objective is an evaluation of the relative biological effectiveness (RBE) of neutrons as a function of the energy with close correlation between the physical pattern of energy deposition and the resultant biological effect. A resultant long term objective is an inquiry into the basic modes of action of radiation on the cell with particular emphasis on the effects of irradiation at low levels. The radiobiological data are combined with physical microdosimetry data in such investigations.

The biological material irradiated is varied and includes the spleen, thymus, and lens, as well as the reproductive and blood-forming organs of the mouse, Drosophila, bacteria, and various plants.

5.0487, FOLLOW-UP STUDY OF IRRADIATED TINEA CAPITIS CASES
R.E. ALBERT, New York University, School of Medicine, *New York, New York* 10016

This ongoing study continues in an effort to determine the nature and magnitude of late radiation injury among the population of 2600 irradiated children and 1900 non-irradiated children with tinea capitis treated at the Skin and Cancer Unit of the New York University Hospital between 1940 and 1958.

Resurvey of approximately 27% of the study sample has been completed to date. Resurvey of the remaining 73% of this population will be continued. The following areas are being evaluated as potential indicators of late radiation injury: illness and mortality, with physical and hospital confirmation; education; occupation; drug abuse and military service.

Data from this phase of the investigation will be collated with data previously obtained from the original survey, medical and laboratory evaluation, and psychiatric interview and psychologic testing, to provide a comprehensive longitudinal profile of the two samples.

5.0488, STATISTICAL ANALYSIS OF LONGITUDINAL GROWTH DATA ON ADOLESCENTS EXPOSED IN UTERO TO THE ATOMIC BOMBS, HIROSHIMA & NAGASAKI
B.S. PASTERNACK, New York University, School of Medicine, *New York, New York* 10016 (AT(30-1))

Since 1950 approximately 1600 exposed and control subjects who were in utero at the time of the atomic bombings (ATB) of Hiroshima and Nagasaki have been studied at ABCC. The PE-86 sample was drawn from the population of in utero children ATB who were either exposed or non- exposed (entering Hiroshima and Nagasaki between October 1945 and October 1955). Matching of subjects was carried out so that all available children exposed under 2,000 m were entered into the study. For each child exposed proximally an attempt was made to include a child exposed distally and one not-in-city ATB -- matched by sex, month of birth and economic status. Children at all stages of gestation were included.

The objectives of this research project are: a) obtain meaningful statistical estimates of biological parameters descriptive of adolescent growth b) determine, using these statistics, whether or not exposure to A-bomb ionizing radiation while in utero has resulted in impairment of growth during adolescence and, if so, c) determine whether or not a relationship exists between estimated radiation dose (computed at ABBC based on air dose curves and shielding information -- T65D) to the mother and the degree of impairment.

Results: During the past year a computer-programmed two stages estimation procedure was developed and applied to the estimation of a four parameter Gompertz-type growth curve (using the variable Standing Height) for each subject in the study. One hundred fifty-nine tables and 13 figures summarizing the results to date are presented. Analysis of exposure effects on growth patterns is now in progress.

5.0489, EFFECTS OF H3 THYMIDINE AS A DNA LABEL IN THE RAT LIVER
J. POST, New York University, Goldwater Memorial Hospital, *New York, New York* 10017 (AT(30-1))

Studies are continuing on the biological effects of radiation using 3HTdR-labeled DNA as the source. They concern the dose-dependent immediate and delayed changes induced in the replication kinetics of normal cells and of tumor cells. Slowing the passage of cells through DNA synthesis and their arrest in G2 are induced on all populations which have thus far been examined. Studies are to be completed upon the levels of incorporated radio-activity of coexistent cell populations in relation to the induced replication changes. The kinetic alterations induced by 3HTdR are being investigated among tumor cells. The model is the carcinogen-induced autogenous sarcoma of connective tissue in the rat. These experiments are designed to control tumor growth. Parallel studies are planned using iododeoxyuridine, since it alters cell replication in ways similar to that observed after 3HTdR.

Finally investigations are planned on the effects of other radioactively labeled macromolecular precursors upon the replicating kinetics of normal cells as part of investigations on the mechanism of action of 3HTdR labeled DNA in altering replication kinetics.

5.0490, INACTIVATION OF ENZYMES BY IONIZING RADIATION

E. SLOBODIAN, New York University, School of Medicine, *New York, New York* 10016

A study is being made of the effects of gamma irradiation on ribonuclease (aqueous). As the OH radical is an important intermediate in the aqueous irradiation effect, parallel experiments are carried out on enzyme samples inactivated by Fenton's reagent, a chemical source of OH radicals. Earlier work had already revealed the formation of new enzymically active and chromatographically similar products from both irradiated and Fenton's treated RNase A.

Recent studies have revealed that both modes of inactivation yield enzyme products which interact with iron in the medium, reducing some Fe III to Fe II, and forming strong complexes with both ions. The techniques of amino acid analysis, viscosity measurement, T-H interchange analysis, and CM-cellulose chromatography are being applied to the study of Fenton's treated samples.

An investigation will be made into the effect of the complexed iron on the characteristics of the enzyme product.

5.0491, RESPONSE OF LIVING CELLS TO HIGH INTENSITY PULSED ELECTRONS AND EXAMINATION OF OXYGEN DIFFUSION KINETICS IN CELLS

E.R. EPP, Sloan Kett. Inst. Cancer Res., *New York, New York*

Oxygen is a well-known sensitizer of living cells, both bacterial and mammalian, to the biological effects of ionizing radiation. In cancerous tissues, the presence of anoxic or poorly oxygenated cells, with their concomitant relative radioresistance, is believed to constitute a problem for successful radiotherapy, and various methods, including hyperbaric oxygen, have been suggested for circumventing or minimizing this effect. The mechanism by which oxygen increases cellular radiosensitivity and the nature of the primary lesions involved remain unkown. It is suspected, however, that short-lived chemical species reactive to oxygen are radiation-induced in critical molecules within the cell. Little is known about the nature of such species or their lifetime.

Using techniques recently developed in this laboratory involving high-intensity pulsed radiation, it is proposed to establish new upper limits to the lifetime of such species and to approach the problem of the actual measurement of oxygen diffusion times in cells. Comparison of diffusion time measurements with those theoretically derived from models will permit estimates of the effective diffusion coefficient for cells to be made.

It is also proposed to examine the role of water in influencing diffusion times by irradiating bacterial spores where the degree of water content can be accurately controlled.

Finally, it is proposed to examine the response of mammalian cells to pulsed irradiation under various degrees of oxygenation. Results in the literature are controversial and some suggest a basis for possible improvement in cancer radiotherapy through the use of high- intensity pulsed electron beams.

5.0492, THEORETICAL INVESTIGATION OF ELECTRON LET SPECTRA AND DOSE RELATIONSHIP FOR IONIZING RADIATIONS

J.S. LAUGHLIN, Sloan Kett. Inst. Cancer Res., *New York, New York* (AT(30-1))

The diffusion of available oxygen into cells immediately after high-intensity pulsed irradiation will be mathematically obtained. A model for a two stage diffusion process is considered, the first stage being diffusion of residual oxygen into critical cell sites from other non-critical areas, and the second being diffusion from the ambience into the cell. Time intervals for the onset of the first and second stage are obtained and numerical values of physical parameters such as cell membrane permeability and diffusion constant will be estimated. Motivation is provided by the increasing application of high-intensity pulsed radiation sources in radiobiology. The approach is mathematical, aided by pertinent experiment data from our laboratory.

Depth-dose distributions and energy and linear energy transfer (LET) spectra are obtained for a number of energies of neutrons incident on a water medium. The radiobiological effectiveness and oxygen enhancement ratio for an incident neutron spectrum will be calculated by the track segment method and compared with available experimental data in order to test the adequacy of LET at very high values as an indicator of biological action.

Results: a. The rate of diffusion of oxygen into cells after high intensity pulsed irradiation was mathematically obtained by means of a two-stage diffusion model. Significant diffusion begins at about 10 to minus the 5th power sec and saturation occurs at about 1 second after irradiation. b. Depth-dose distributions for monochromatic neutrons in water were compiled. Linear energy transfer (LET) spectra were obtained in the case of monochromatic neutrons incident on a water medium. Part 2 of 11.

5.0493, RADIATION MECHANISMS IN MAMMALIAN SYSTEMS

J.S. LAUGHLIN, Sloan Kett. Inst. Cancer Res., *New York, New York* (AT(30-1))

We propose to continue studies on the mechanism of action of radiation on living cells. Single strand breaks in DNA following irradiation will be determined in sublines of HeLa cells which differ in radio-sensitivity, under oxygenated and anoxic conditions. In addition, we plan to investigate whether nuclear membranes may be involved in the radiation response of synchronized cells.

We will continue studies on OER of cyclotron generated neutrons at different depths of the phantom, and we are planning studies of RBE and OER of neutrons generated from Cf252 sources.

Results: (a) It was found that RBE of cyclotron generated neutrons decreases with depth in a phantom. (b) Enzyme activity is not decreased after supralethal doses of irradiation, and irradiation affects the enzyme-producing pattern only by distorting cell cycling. (c) BUdR decreases survival of HeLa cells when given either before or after irradiation, indicating an indirect mode of sensitization. Part 3 of 10.

5.0494, SR-90 METABOLIC BALANCE STUDIES

E.P. HARDY, U.S. Atomic Energy Commission, Health & Safety Laboratory, *New York, New York* 10014

Cooperative studies on Sr-90 metabolism in adult males have been carried out with Dr. Herta Spencer of the Hines Veterans Hospital in Chicago since 1959. A metabolic ward for controlled diet and excretion measurements is under Dr. Spencer's supervision. Samples of diet and excreta collected over 6-day periods are analyzed at HASL for Sr-90. These investigations are carried out to determine the extent to which various dietary supplements either enhance the removal of deposited Sr- 90 from the body or inhibit the absorption of dietary Sr-90.

Results: The main effect of stable strontium given orally or intravenously was an increase in urinary Sr-90 excretion. Intravenously infused stable strontium increased the urinary Sr-90 excretion by a factor of 3 while orally administered stable strontium increased the urinary Sr-90 excretion only by a factor of 1.5.

5.0495, IRRADIATION EFFECTS ON DENTAL AND ORAL PROCEDURES

G. COHEN, U.S. Veterans Administration, Hospital, *New York, New York* 10010

Twelve long-term irradiated animals are still to be histologically assayed. Six received 240 KV and six received C60 through bilateral portals exposed to the maxilla and mandible.

Animals previously sacrificed following irradiation with the above modalities and with various time sequence surgical procedures performed, showed impairment of healing of extraction sites more so markedly in animals treated with ortho voltage. No sequestration of an entire mandibular body was noted.

SUPPORTED BY U.S. Veterans Administration

5.0496, EFFECT OF RADIATION ON GLUCOSAMINOGLYCANS IN BONE

K.I. ALTMAN, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620

The central theme of which the proposed project represents one aspect, concerns the effects of ionizing radiation and aging on the metabolism of connective tissue. The tissue of interest in this study is bone, i.e., the long bones of hind legs. Attention is to focused on glucosaminoglycans (GAG), a major class of constituents of ground substance. Because of known influence exerted by ionizing radiation and aging on the metabolism of this class of compounds, a study of the metabolic behavior of GAG as an integral part of connective tissue of normal bone is envisaged in relation to X-radiation and aging (physiological as well as 'radiologic').

Recent work from other laboratories indicates that the metabolism of GAG is intimately involved in the formation of callus during the healing of fractured bone and that the process leading to closure of the fracture is affected by exposure to x-radiation and by the age of the organism. We are,therefore, presented here with an opportunity for studying radiation and aging effects on a metabolically active system capable of synthesizing GAG.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0497, MECHANISMS OF PERMANENT AND DELAYED PATHOLOGIC EFFECTS OF RADIATION

G.W. CASARETT, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT(30-1)49)

This is a multidisciplinary investigation in total-body X- irradiated rats of: a) the pathogenesis of 'permanent' and delayed damage of parenchymal, connective, and vascular tissues and of induction and/or temporal advancement of degenerative diseases, neoplasms, and aging changes in life-span shortening; and (b) post-irradiation treatments against these effects. Some previous findings include: (a) endothelial damage with plasmatic transudation through small vessel walls into organ parenchyma leads to increasing vascular and interstitial fibrosis (histohematic connective tissue diffusion barrier) additive with similar progressive changes of aging and to increasing blood pressure which contributes to degeneration and fibrosis of fine vasculature, and these progressive changes largely cause the subsequent premature degeneration of organ parenchyma leading to delayed effects; and (b) treatment of rabbits with epsilon amino-n-caproic acid (EACA) after skin irradiation reduces early plasmatic transudation, vasculo- connective tissue changes, and severity of delayed skin pathology, and treatment of rats with L, 3, 3, 5-triiodothyronine (T-3) after total- body irradiation prevents or reverses the increases in fibrillar connective tissue in organs caused by irradiation or natural aging. Current and continuing next year are more definitive, comprehensive life-term rat experiments on efficacy and mechanism of T-3 or EACA treatment against the late effects.

Results: In current experiments trends of data, including periodic quantitative or semiquantitative cytology, histology, histopathology, histochemistry, biochemistry (connective tissue, thyroid and adrenal hormones, electrolytes), O2 consumption and other metabolic factors, blood pressure and other hemodynamic factors, microcirculatory factors, microangiography, hematology, pathology (age-related disease incidence), auto-immune aspects of thyroid damage, and actuarial parameters, are confirming and strengthening previous findings, theory, and expectations. Experiments have not gone long enough in life-span for conclusions concerning delayed effects and treatments.

5.0499, FATE OF RADIUM AND OTHER RADIONUCLIDES IN LIVING ORGANISMS

J.B. HURSH, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT(30-1)49)

The objective of this program is to perform biological experiments on the intake, tissue distribution, and fate of radionuclides, and to produce data of use in the setting of maximum permissible levels in the air and water of the occupationally exposed personnel. Current emphasis is on various isotopes of lead. An important body compartment for concentration and storage of lead is the red cell. A considerable amount of research has been published on the mechanism by which lead is bound to the erythrocyte, but the problem is still unsolved. It is proposed that lead binding by the red cell be investigated including a study of the uptake, if any, by red cell ghosts and the effect of various levels of stable lead on the rate of uptake and the fractional distribution between cells and plasma. This is intended as an in vitro study and will use human blood. In addition, it is proposed that a study be initiated using beagle dogs who are to inhale labelled tungstic oxide. The deposition, rate of lung clearance, and excretion will be measured.

Results: The results of a study on Pb212 inhaled by man have been published in Journal of Applied Physiology, Vol. 28, 268. A paper entitled 'Tissue Distribution of Bi212 in Rats' has been published in Proc. Soc. Expl.Biol. Med., '131, 116. A paper entitled 'Oral Ingestion of Uranium by Man' has been published in Health Physics, 17, 619.

Dogs have been exposed to 210 Pb210 aerosol and sacrificed at 2, 11, and 31 days. The lung clearance of the lead aerosol showed half- times from 4-11 hours. Red blood cells, liver, and bone showed the highest Pb210 content on sacrifice. The urinary to fecal ratio of excreted lead was about 1.

5.0500, HEMATOPOIESIS IN NORMAL AND IRRADIATED ANIMALS

M. INGRAM, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT(30-1)49)

The response to a suddenly increased demand for increased blood cell production may include production of non-standard or aberrant cells as well as increased production rates. Studies in progress are concerned with the application of such measurements in evaluating hematopoietic competence of normal animals (dogs, rats). They are also applied in comparing hematopoietic competence of normal animals with that of aged and irradiated animals. Normal young adult dogs, old and old dogs X-irradiated

many years earlier are subjected to severe acute blood loss. The erythropoietic, thrombocytopoietic and leukocytopoietic responses are evaluated with respect to production rates and the characteristics of the cells produced. Erythropoietin assays provide additional information about the erythropoietic response. (Possible 'thrombopoietin' assay systems are also being evaluated.) Age: volume: density relationships of blood cells produced by the various experimental groups following blood loss or irradiation are altered in different ways.

Results: Differences in the erythropoietic responses of young adult, old, and old-irradiated dogs have been demonstrated, although the groups appear not to differ significantly with respect to erythropoietin production. Aberrations in platelets and leukocytes produced after severe blood loss have also been demonstrated. Preliminary evaluation of assay systems for thrombopoietin, using animals made thrombocytopenic by various means have been completed and are being written up as a Ph.D. thesis and for publication.

5.0501, THE CELLULAR AND MOLECULAR BASIS OF RECOVERY FROM RADIATION INJURY

C.S. LANGE, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT(30-1)49)

The aim of this project is to explain the mechanism(s) of organismal recovery from radiation injury in terms of stem cell repopulation and differentiation, which are studied in the animal, and cellular recovery and repair of sublethal damage, which are studied in culture. The ability to repair, and possibly the induction of sublethal damage have been shown to be limited to specific times in the cell cycle. Specific inhibitors of DNA, RNA, and protein synthesis are being used to determine the molecular mechanism(s) of repair in mammalian cells (HeLa). The planarian is a useful analog for mammalian cell systems such as bone marrow, liver, skin. By determining planarian survival curves and stem cell counts after dose fractionation, shielding, and stimulation of differentiation, the nature of the control system(s) which govern(s) repopulation is being studied. Isolation and identification of the tissue-specific differentiator hormones of the planarian is also being done to elucidate the mechanism of differentiation control and stem cell homeostasis.

5.0502, BIOLOGIC AND PHYSICAL ASPECTS OF AIRBORNE AGENTS

L.J. LEACH, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT(30-1)-49)

A great variety of atmospheric pollutants enter the body through the respiratory system. Many are capable of producing disease or disability when deposited or accumulated in sufficient amounts in the lungs or after translocation from the lungs to sites deeper within the body.

The purpose of this project is to gather more information on inhaled materials primarily through animal experimentation.

Currently, the long-term biologic effects of inhaled uranium are being evaluated in dogs and monkeys that have been exposed daily to natural UO2 dust (5mg U/per cubic m) for periods up to 5 years and then held for as long as 6 years postexposure.

Studies are also being made to determine the health hazards associated with the inhalation of selected compounds from the lanthanum series. For example, single (1 day) and multiple (90 days) exposure of dogs and monkeys to an aerosol of europium oxide (Eu_2O_3) at 6.5 mg/per cubic m, mean concentration, have been completed. Exposed animals along with control groups were examined routinely for changes in general health, body weight, hematology and histology. Concentrations of Eu in tissues and excreta were determined by activation analysis.

The inhalation toxicity of lutetium oxide (Lu_2O_3) is presently under investigation.

Results: The most consistent findings in the UO2 exposed animals examined during the postexposure period were fibrotic changes in lungs and associated lymph nodes which probably reflect alpha radiation injury.

No animals died during the 3 month exposure to Eu_2O_3 aerosol. The treatment had no major effect on growth patterns or peripheral blood pictures of the test animals. The primary sites of Eu accumulation were the lungs and tracheobronchial lymph nodes. Fecal excretion appeared to be the main pathway by which Eu was cleared from the body.

5.0503, PHYSIOLOGIC DECREMENTS OF ELECTROMAGNETIC RADIATION EXPOSURE

S.M. MICHAELSON, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT(30-1)49)

The neuroendocrine system which plays a major role in coordination and integration of body functions is susceptible to ionizing radiation. Quantification of radiation-induced functional alteration of this system is required. Although the thyroid gland was, in the past, considered to be fairly resistant to external X- or gamma radiation, it has become increasingly evident that exposure to a 'moderate' level of X-rays (100 R) can result in thyroid dysfunction and neoplasia. The relative radiosensitivity of this important endocrine organ has not been established. The numerous interacting factors such as mode of irradiation, total dose, dose rate, age of subject, relationship of other body systems which may be concurrently exposed to radiation or are affected because of their inter-dependence of reciprocal relationship with the thyroid, have to be worked out. Interpretation of the effects of radiation on the thyroid must be made in light of the functional interrelationships of this gland with the hypothalamic-hypophysial and other coordinating systems of the body. The dog exposed to various modes of X-irradiation such as to the upper-body, head or neck, is used as the biomodel to assess basic biologic reactions and possible health implicatons for man. These studies emphasize the need to examine the role played by neuroendocrine mechanisms in the radiation induced pathophysiology of the thyroid gland.

Results: Histopathology of the thyroid reveals a higher than expected incidence of neoplastic changes. Assay methods for thyroid stimulating hormone (TSH) and growth hormone (GH) in the dog are in various stages of development and refinement. The mouse bioassay for TSH has been standardized. The radioimmunoassay for human TSH has been standardized and the method will be applied to the dog as soon as a sufficient number of canine pituitaries is obtained for specific TSH extraction. Initial studies indicate that radioiodinated canine growth hormone cross-reacts with guinea pig anti-porcine growth antiserum.

5.0504, CELLULAR PARAMETERS OF RADIOSENSITIVITY

M.W. MILLER, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT(30-1)49)

The nucleus and chromosomes are primary targets for radiation- induced effects upon cellular reproductive integrity. The objective is to compare the relationships between nuclear and chromosomal size and radiosensitivity, particularly with polyploid (multiple sets of chromosomes) species; also, the factors involved in studying repair of irradiated chromosomes are under investigation. The proposed research has followed two avenues: (1) exposing series of polyploid plant species to ionizing radiation and scoring for survival, and (2) combining dose-fractionation experiments with multiple fixation studies to determine the relation between sensitivities (chromosome breakage) and cycle speeds of cells within the root meristem of 'Vicia faba'.

Results: Polyploidy per se does not appear to confirm radioresistance; rather, the smaller chromosome sizes of the resistant species correlates with their high radioresistance relative to the diploid species.

Single fixation times in studying dose fractionation effects on chromosome breakage can give false impressions about yield; multiple fixations indicate a heterogeneity of the cells with regard to radio- sensitivity and cycle speed.

5.0505, THE RADIOBIOLOGY AND TOXICOLOGY OF RADON AND OTHER RADIOACTIVE GASES

D.A. MORKEN, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT(30-1)49)

The inhalation of radon and its decay products is believed to produce lung cancer in uranium miners. It is the purpose of this work with radon to examine the radiological effects which result from the inhalation of radon. These biological studies with radon include effects on life span, the hemopoietric system, histology, morphology and general pathology, with specific attention directed to the lung. Exposures to radon extend from single and multiple short time inhalations of radon only to continual inhalations of radon and its decay products over a wide range of concentrations of radon in air. Mice and a few rats have been used, and dogs are now being used.

Exposures to x-ray are used as reference irradiations. Some experiments, in studies of the hemopoietic system, have included combined radon and x-ray exposures.

A graduate student has begun a study of the effects of inhaled krypton-85, with guinea pigs, to differentiate the results of internal from external irradiations. Visiting scientists are studying chromosome aberrations in rats exposed to radon. The use of radon offers a unique opportunity to expose animals continually, by inhalation, to maintain a constant body burden of alpha-emitting isotopes but which, by virtue of a rapid elimination rate and short-lived decay products, reduces body content of radioactivity to a negligible amount on termination of exposure.

Results: Morphological changes in trachea and lung of mice occassioned by continual exposure to radon are repaired within a few weeks following termination of exposure. Late effects appear in the region of the terminal bronchiales. The lungs of dogs at 6 months and 1 year past exposure to doses from 200 to 3000 working-level-months have shown only tenuous changes in morphology. Other dogs will be examined at 2 and 3 years past exposure. Exposures now in progress will deliver doses of about 12,000 working-level-months to dogs.

5.0506, CLINICAL RADIATION RESEARCH CENTER

P. RUBIN, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620

The aims of this program are the systematic delineation of the fundamental cellular and tissue responses, and mechanisms, in vivo in normal and malignant neoplasms of various kinds and levels of radiosensitivity, during and after radiation exposure in various temporal modes; and the application of this knowledge to the discovery of physical, physiologic, and chemical means for the most efficient use of radiation and adjunctive agents in the destruction of cancer and sparing of normal tissues. The coordinated multidisciplinary parameters include cell and tissue growth rate and survival, tumor metastatic incidence and potential, histopathology, histochemistry, biochemistry, cytokinetics, cell viability, cellular ultrastructure, cell physiology, vasculogenesis, microangiography, vascular and circulatory physiologic responses, oxygen influences, oxygen determinations in tissues, and other special techniques as required. Currently being maintained in serial passage (transplantation) in the Syrian hamster cheek pouch for these studies are 3 types of Syrian hamster sarcomas, 4 types of Syrian hamster carcinomas, 1 polyoma virus transformed Syrian hamster sarcoma, and 2 human carcinomas. Studies of carcinogenesis and cancer induced by DMBA in hamster cheek pouch and by subcutaneous implantation of teflon in hamsters, have been initiated. Other transplantable and induced tumors will be added for these studies.

5.0507, MODIFICATION OF RADIATION INDUCED PULMONARY FIBROSIS

B.F. SCHREINER, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620

The research objectives of this project are directed toward a more complete understanding of the effects of primary pulmonary irradiation in the dog. During the past five years we have carefully defined the syndrome of pulmonary radiation effects in terms of dose time intervals, clinical course, hemodynamic abnormalities, alterations in blood gas exchange, and changes in thoracic roentgenograms. Correlations between these changes and pathologic changes have been made. We now propose to evaluate this syndrome further by (a) estimating the magnitude of increased pulmonary parenchymal metabolism; (b) studying the efficacy of (1) pharmacologic interventions such as triiodothyronine and cortisone, and (2) physical conditioning; (c) an investigation of the magnitude of impaired myocardial performance; and (d) an ongoing electron microscopic study of the primary nature of the radiation reaction, i.e. vascular or epithelial.

5.0508, ACUTE RADIATION EFFECTS OF WHOLE-BODY X-IRRADIATION IN ANIMALS AND SUITABLE THERAPY

L.T. STEADMAN, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT(30-1)49)

An effect being investigated is the finding that a circulating toxic material is produced during the irradiation of animals. It comes mainly from the muscles. After isolation from tissues or urine and then injection into a normal test rabbit, it will reproduce much of the initial radiation shock-like syndrome, and it also enhances the later hemorrhagic effects. There is a small normal excretion in laboratory animals and humans. Present objectives include determining the chemical nature of the material, its manner of production, and its physiological significance and mode of action in the irradiated animals.

Another effect is the high incidence in the second week post irradiation of peptic ulcers in rabbits and general stomach lesions in guinea pigs which in both species lead to internal bleeding and death. The etiology of these hemorrhagic effects is a prime objective, and the role of the toxic material in this connection is being defined. For example, the ulcers have a higher concentration of the toxic material than the rest of the mucosa and the material is a vasodilator. Antacids and anticholinergic drugs are useful therapy measures and protective agents are being tried.

RESULTS: On irradiating part of the rabbit's stomach through small ports, the dose necessary to produce ulcers in the mucosa increases with diminishing port size.

A chemical protective agent has been employed which is able to inactivate the toxic material in vitro and also in vivo, as evidenced by lowered tissue levels in irradiated animals. Rabbits thus protected show no shock effects or early death for 1300 R, and the mortality due to the stomach lesions is markedly reduced. Similarly, the LD 50% for guinea pigs has been raised from 330 R, for controls, to about 430 R.

5.0509, DYNAMIC ASPECTS OF SKELETAL METABOLISM

A.R. TEREPKA, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT)

This is a continuation of a long-term research project exploring the major factors involved in calcium homeostasis, i.e., the entry and egress of calcium into and from the skeleton and the interrelationships of hormones (parathyroid and others) and vitamins (vitamin D and related sterols). Specific, but interrelated aspects of the study are: 1) blood-bone exchange of bone-seeking isotopes in man and 2) calcium deposition, resorption and transfer in special experimentally adaptable systems (hen and egg).

Results: Calcium transport by the isolated chick chorioallantoic membrane has been studied in great detail. Particular attention has been directed toward the bioenergetics of the process and the morphological aspects of active calcium transport.

The electron probe microanalyzer has been used to elucidate the mechanism of calcium compartmentalization characteristic of the tissue.

5.0510, MORPHOLOGICAL AND CYTOLOGICAL STUDIES OF LUNG RESPONSES TO INHALATION AND IRRADIATION

C.L. YUILE, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT(30-1)49)

The research is designed to define the pathological effects of various inhaled particulates on lung structure and to correlate such effects with chemical and radioactive measurements. The study is being conducted to obtain basic morphologic information concerning short and long term toxic effects and pulmonary clearance mechanisms, of a general as well as specific nature, related to materials encountered as environmental or industrial inhalation hazard . After single or multiple exposures to aerosols of various, generally isoluble materials, the lungs of exposed animals are examined by light and electron microscopy and by autoradiography when indicated. Structural alterations are also studied at different time intervals after external thoractic X-irradiation in order to separate chemical and radiation effects of inhaled radioactive materials. Rats and dogs are the test animals being used while aerosols of the rare earths europium and lutetium, natural uranium and radioactive isotopes of plutonium (Pu238 and Pu239) are generated in special chambers for inhalation exposure.

Results: Despite an early inflammatory and macrophage response in the lungs and ultimate storage in pulmonary interstitial tissues and lymph nodes after 3 months of daily europium inhalation, no obvious, adverse reaction had occurred within 1 year. In 13 dogs exposed to an aerosol of natural UO2 for 5 years, slight fibrosis of lungs and pulmonary lymph nodes and epithelial proliferative lesions in the lungs ranging from focal alveolar metaplasia to frank adenocarcinoma, developed during post-exposure periods of from 12 to 84 months. No such lesions occurred in 5 control dogs. In monkeys, subjected to similar experimental conditions, no tumors occurred, but pulmonary and lymph node fibrosis was marked. Dose related pulmonary and hematopoietic effects of inhaled plutonium-238 and 239 have been worked out over a considerable range of initial dose and post-exposure time and results are to be published.

5.0511, RADIATION EFFECTS IN CROSS-LINKING IN POLYMERIC SYSTEMS

G. ODIAN, City University of New York, Graduate School, *Staten Island, New York* 10301 (DA)

Technical Objective: Mechanistic studies will be made in the areas of radiation-induced graft polymerization and cross-linking. Extension of knowledge in types of polymerization, and cross-linking in polymer- monomer systems, should lead to improved properties sought by the Army for the thermoplastic materials such as those used in electronic apparatus, mechanical goods, rifle stocks and containers for ammunition and other supplies.

5.0512, BEHAVIORAL AND NEURAL EFFECTS OF RADIATIONS AND TOXINS

J. GARCIA, State University of New York, School of Arts, *Stony Brook, New York* 11790

This research deals with behavioral effects of illness induced by X-rays and toxins. Previous research has indicated that when animals ingest a distinctly flavored fluid and become ill even hours later, they will learn to avoid that flavor in a single trial. Present research indicates that this long interval between tasting the substance and the subsequent illness state is spanned by a central (memory) mechanism and does not depend upon lingering remnants of the meal. Wet food, as opposed to dry food with water separate is a sufficient cue when followed by illness induced hours later. Taste signals followed by illness reinforcement appear to be a necessary condition for this 'long interval' conditioning. Taste followed by peripheral pain of shock is not effective with long delays. Smell, as well as visual and auditory signals, followed by illness appears to be ineffective also. We have evidence that taste-illness learning is not controlled by the same central neural mechanisms as buzzer-shock learning. Septal lesions will disrupt buzzer-shock associations but they actually improve taste illness associative learning. Amygdaloid lesions disrupt both types of conditioning. We are now exploring gustatory projection areas to locate lesions which will disrupt taste-illness association but leave buzzer- shock learning intact. In this way, we hope to learn the organization of differential neural control of the internal and external environments.

During the next year we expect to extend our behavioral research to other species, particularly monkeys to test for the associative bias we demonstrated in the rat.

5.0515, OPTIC LENS OF MAN - INCIDENCE OF MINUTE, DISCRETE SUBCAPSULAR OPACITIES WITH AGING OR FOLLOWING IRRADIATION

J.L. BATEMAN, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

Whereas interest in the effect of ionizing radiation upon the lens of man has been usually directed toward gross lesions which reduce visual acuity, the question arose as to whether minute measurable changes occurred as have been found in the mouse, with aging or irradiation. This information might pertain not only to the relation of aging and irradiation, but also to the significance of low level occupational or incidental exposure in man.

Laboratory employees exposed to very low levels of radiation and metastatic cancer patients maintained on cytotoxic drugs were utilized to develop a workable method of lens examination and opacity scoring. It was found that the same instrument and technique could be used as have been employed in experiments utilizing mice. It is intended to examine persons both unexposed and exposed to ionizing radiation of known physical characteristics, towards elucidation of the relation of aging to irradiation in the human lens, and to the extent possible, to correlate lens changes in the irradiated individuals with the radiation physical factors.

Results: Examination of Marshall Island residents in February- March, 1969, included 80 unexposed persons and 41 exposed to 175 r of whole-body gamma rays from fallout caused by the 1954 nuclear detonation at Eniwetok. Minute discrete opacities were found to increase steadily with age in non-irradiated males, while normal females showed a rapid rise during adolescence and a slower increase thereafter. Among the irradiated persons, only females who had been adolescent at the time of the fallout exposure revealed an incidence of minute discrete opacities suggestively higher than their non-irradiated peers.

5.0516, BIOENERGETIC MECHANISMS INVOLVING FREE RADICALS - RADIOMIMETIC MECHANISMS AND IRRADIATION STUDIES RELATED TO AGING
D.C. BORG, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

Continuous flow apparatus for electron paramagnetic resonance (EPR) spectrometry of labile free radicals in liquid at X-band and Q- band will be further applied to radiomimetic chemical reactions (due to hydroxyl radicals produced by Ti(III) /H2O2) that form transient free radicals from biochemical substrates. Purines, pyrimidines, and other componets of nucleic acids will be studied to determine mechanisms of free radical attack and to relate these to natural and radiation- accelerated aging effects on somatic DNA.

Hydrogen and deuterium atom bombardment and irradiation of powders and crystals of some of the same materials will be continued to assist in free radical identification and to correlate some radiation effects in static solid samples with flow-system observations of reactions in liquid.

Results: The radiomimetic chemical system's action on several amino acids gave complex EXP spectra. Analyses indicated multiple free radical fragments, including prodcts that had undergone hydrogen abstraction and deamination, which is comparable to results from radiolysis.

Atom bombardment of dry samples of purines and pyrimidines permitted description of the radiation damage centers in several cases. Much work was done with 9-methyl adenine and 1-methyl thymine.

5.0517, KINETICS OF HEMATOPOIETIC STEM CELL PROLIFERATION FOLLOWING X-IRRADIATION
A.L. CARSTEN, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

The objective is to relate changes in marrow stem cell activity to mortality following uniform or non-uniform radiation exposures; also to elucidate the kinetics of stem cell proliferation and differentiation and their influencing factors. Changes in stem kinetics related to age, strain, and sex are investigated. The relationship of depth dose, marrow distribution and mortiality is being examined following various geometry exposures in mice and monkeys.

Changes in marrow stem cell numbers with age of male mice have been measured out to 103 weeks of age, and related to recovery to 65 weeks following a maximum sublethal whole body dose of 525 rads. The observations on the viability of stored marrow have been extended to determination of resultant colony morphology as well as numbers. Comparative data on marrow distribution in mice, monkeys, dogs and man have been compiled.

5.0518, COMPARATIVE STUDY OF THE EFFECTS OF X-IRRADIATION ON THE ELASMOBRANCH BRAIN
A.L. CARSTEN, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

The differing morphology and reaction to physical injury of the elasmobranch brain has led to the study of the effects of gamma irradiation on the role of the astrocyte, its metabolism and modification following irradiation injury. In addition, changes in the blood brain barrier permeability are also examined. Studies include histological and electron microscopic examinations of animals as early as 24 hours following gamma exposures in the 1,000 to 30,000 rad range made with a 1 cm cross section beam. Similar measurements are being made on animals as late as 16 months post exposure with the same beam geometry at dose levels of 1,000 - 5,000 rads. A number of cats and rats received identical exposures to the forebrain or cerebellum, and were used for comparative studies with the sharks.

Results: Whereas the rats and cats exhibited the well documented pattern of irradiation necrosis and attendant loss of function, the exposed sharks showed only the most minimal changes. No abnormality with regard to mobility, behavior or growth could be detected in any sharks. The only discernible changes in the irradiated region were a slight subcutaneous edema in animals sacrificed at 5 to 9 days following 30,000 rads and a slight local darkening of the skin at 4 to 9 days following 30,000 rads and a slight local darkening of the skin at 4 to 16 months in animals receiving 5,000 rads. Studies of vascular permeability using labeled proteins indicated the same pattern of response, i.e., no abnormal vascular permeability in the irradiated region of the shark brain in contrast to the increased permeability in the mammals.

5.0519, PATHOGENESIS OF EARLY AND LATE EFFECTS OF X-IRRADIATION ON THE RAT AND MONKEY FOREBRAIN
A.L. CARSTEN, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2))

The ultimate aim is to correlate structural change and functional alteration in the mammalian brain following X-irradiation. Functional integrity is evaluated by EEG analysis of the visual evoked response or visual acuity in the monkey, and by maze running ability in the rat. Rhesus monkeys received 3500 rads limited to either the right visual cortex in EEG tested animals or both visual cortices in the visual acuity tested animals. In addition one-half of the EEG tested animals underwent pre-irradiation surgery to eliminate the hemispheric connections in the optic chiasms and corpus callosum. Rats received forebrain exposures of 2,500 to 5,000 rads followed by testing of maze running ability at 4 to 36 weeks post exposure. Both monkeys and rats are sacrificed at various times post exposure for complete light and electron microscopic evaluation.

Confirmation of a decreased EEG amplitude in the right irradiated hemisphere with a later bilateral depression is complete. Monkeys have undergone surgical section to separate the right and left hemispheres and irradiation. Animals receiving 3,500 rads to both visual cortices showed no decrement in visual acuity until 90 days, after which these animals showed a rapidly developing reduction in visual acuity leading to functional blindness within approximately 60 days. Forebrain irradiated rats (3,500-5,000 rads) show an earlier period of learning decrement (15-30 days post exposure) followed by a return to more normal patterns of learning when examined some weeks later. Histopathology on the rats indicates the type of radiation necrosis previously reported.

5.0520, LYMPHOCYTE MIGRATION AND KINETICS IN EXPERIMENTAL ANIMALS
A.D. CHANANA, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

Extracorporeal irradiation of blood (ECIB) and lymph (ECIL) destroys circulating lymphocytes without direct radiation damage to hemopoietic organs. These techniques enable development of quantitative methods for the study of normal and malignant lymphopoiesis. ECIB and/or ECIL will be combined with: (1) in-vitro or in-vivo isotopic labeling of cells; (2) sampling of blood from individual organs; (3) isotopic labeling of individual organs in situ, and (4) sizing of lymphocytic population of blood and lymph. It is hoped to clarify the magnitude of lymphocyte recycling from blood to lymph; life span, mobilization and production rates of normal and leukemic lymphocytes; mechanisms controlling lymphocyte production; stem cell capabilities of lymphocytes; influence of lymphocyte destruction on new cell production; routes of migration of thymic lymphocytes to other organs and magnitude of this migration; and role of lungs and spleen in lymphocyte homeostasis.

Results to date: Lymphoid cells proliferating in the thoracic duct of the calf represent two populations. The cells with more basophilic cytoplasm have shorter DNA synthesis and generation times. The mitotic time of these cells was not altered by prior

ECIB. The newly synthesized thymic lymphocytes enter the circulation via the thymic vein and thymic efferent lymphatics and the newly synthesized lymph node cells enter the circulation via the efferent lymphatics. Labeled thymic lymphocytes were observed in the thoracic duct lymph. Size distribution analysis of blood and thoracic duct lymphocytes of the calf did not reveal any significant differences.

5.0521, THE LONG-TERM TURNOVER OF RADIONUCLIDES IN MAN

S.H. COHN, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

The sensitivity, precision and accuracy of the whole-body counter permits the measurement of the long-term biological turnover of various elements in man using low levels of tracer. Knowledge of these turnover rates is required for the assessment of the radiation hazard to man from 90Sr, 137Sr, 137Cs and 65Zn. In a current study, the long-term turnover of both chronically-administered 85Sr and a single intravenously- administered dose are compared over one-year periods. Mathematical models representing the turnover data are developed with the aid of a digital computer to permit extrapolation over a lifetime. At late times after administration, the tracer data reflect the turnover rate of the slowly-exchanging or 'stable' bone compartment. From these data it is possible to derive the function describing the rate of loss of Ca from bone to plasma.

Results: A stochastic model (within a compartmental analysis) using the likelihood function was formulated to fit long-term strontium retention data. This model is an analytical representation of a system having a unique outcome, within a probabilistic range, for a given set of values.

5.0522, INFLUENCE OF AGE AND RADIATION EXPOSURE ON HUMAN LYMPHOCYTE RESPONSE TO PHYTOHEMAGGLUTININ (PHA)

R.A. CONARD, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-1))

The effect of age and radiation exposure was studied in phytohemagglutinin stimulated blood cultures in 40 Marshallese who had been exposed to fallout radiation and in 130 unexposed Marshallese. Similar 'in vitro' studies were carried out studying the effects of X- radiation on PHA-stimulated lymphocytes in 15 subjects at BNL. Electronic sizing was used in both of these studies to determine the percentage of transformation of lymphocytes in culture.

Results: Percentage response of lymphocytes to PHA stimulation in culture decreased progressively with increasing age. Response in the exposed population however was about the same as in the unexposed population. 'In vitro' irradiation of PHA-stimulated lymphocytes showed the greatest effect to be on cell division whereas the transformational ability of the lymphocytes was less impaired. These studies have been completed and are being published.

SUPPORTED BY U.S. Atomic Energy Commission

5.0523, MEDICAL STUDIES OF THE PEOPLE OF THE MARSHALL ISLANDS ACCIDENTALLY EXPOSED TO FALLOUT

R.A. CONRAD, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

Annual medical surveys of the Marshall Island people who were accidentally exposed to radioactive fallout in 1954 are conducted by Brookhaven National Laboratory in conjunction with the Trust Territory of the Pacific Islands. The most important late effects noted in this population has been growth retardation in some of the exposed children and during the past 5 years the development of thyroid abnormalities in 21 out of 82 exposed people of Rongelap Island. These latter abnormalities are believed to be a result of exposure to internal radioiodines absorbed at the time of the fallout. Seventeen out of the 21 lesions have occurred in persons less than 10 years of age when exposed. Surgical exploration of the thyroid has been carried out in 19 Marshallese people in the U.S.

Results: As a result of the 1969 (15 year) survey 5 Marshallese thyroid cases were brought to BNL for study and later surgery at Cleveland, Ohio. Of the 5 cases, 3 proved to be malignant lesions. In addition to the 3 cases of thyroid cancer 15 benign nodules and 2 atrophic glands have been detected in the exposed Rongelap people. Correlation of growth retardation with thyroid injury has been apparent in some of the children and supplemetal thyroid hormone therapy appears to be beneficial.

5.0524, BIOLOGICAL MECHANISMS OF NATURAL AND RADIATION-INDUCED AGING

H.J. CURTIS, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

Aging in mammals is considered a result of a complex series of biological reactions, each of which is due to a different cause. Probably most of them involve changes in the nucleus of one or more somatic cells, so mutations, broadly defined, are implicated. Radiation causes mutations and thus accelerates aging. It is a powerful tool for the determination of specific factors involved in the reactions, and especially the role of recovery mechanisms. Mutations are scored in mice either as visible chromosome aberrations or as the per cent tumor incidence under rigidly defined conditions. Age-associated changes in DNA and RNA are being studied by both biochemical and molecular biological methods.

Results: Studies have confirmed and extended the above theories of aging. All somatic cells undergo mutation at roughly the same rate throughout life, and if they do not undergo division (e.g., liver) the mutations accumulated at a constant rate. If they continually divide (e.g., bone marrow) the aberrant cells are selected against and the aberrations remain at low levels. Even without division chromosome breaks may be repaired over a period of many months but the point mutations responsible for cancer are never healed. In the human, most degenerative diseases require cellular changes involving about 6 sequential steps for induction, at least one of which is a mutation in a somatic cell.

SUPPORTED BY U.S. Atomic Energy Commission

5.0525, RECOVERY OF IRRADIATED MAMMALIAN CELLS

M.M. ELKIND, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

The purpose of this work is to learn the mechanism whereby mammalian cells can repair radiation damage related to the division process. Since repair mechanisms may be the reverse of, or at least closely related to, mechanisms of damage registration, the objective is also elucidation of how radiation kills cells. This study is undertaken, to begin with, because lethality is one of the main biological effects of radiation but also because an understanding of radiation damage/repair processes is essential to the improvement of the treatment of cancer with radiation. Experimentally, cultured mammalian cells are used because they facilitate quantitative measurements and because in general their radiation properties are similar to the stem cells of essential cell renewal systems in the body as well as malignant cells undergoing uncontrolled growth in tumors. In addition to the effects of radiation by itself on colony formation, the influence of drugs which can affect radiation damage or repair are also studied to help in the understanding of the radiation problem.

Results: At the level of cell survival, we have found that sublethal damage can be repaired and that lethal and sublethal damage differ only in degree. To find a molecular basis for these results, we have studied damage/repair at the level of single strands in DNA. As found also by others we observe that cells repair single strand breaks rapidly. However, they also have an ability to repair a second form of damage which is related to DNA in a larger organizational structure. Radiation resolves this structure and during a repair interval, cells reverse the effect of radiation.

5. RADIATION

SUPPORTED BY U.S. Atomic Energy Commission

5.0526, THE GENETIC EFFECTS OF IONIZING RADIATION IN DROSOPHILA MELANOGASTER
F.W. GONZALEZ, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

Mature Drosophila sperm will be irradiated with a mixed dose of neutrons and X-rays in an attempt to detect interaction between chromosome lesions produced by X-rays and similar lesions produced by neutrons. If such an interaction can be detected, the rejoining distance between chromosome lesions can be calculated. At present only upper limits of this distance can be estimated. The finding of such an interaction will also eliminate one of two models that explain observed linear dose-response curves for neutron-induced chromosome exchange and translocations.

Recently Savage has proposed a new hypothesis for chromosome exchange that differs fundamentally from the generally accepted hypothesis of Wolff. Mature 'Drosophila' sperm of various karyotypes will be irradiated and their translocation frequecies determined to test these two hypotheses.

Mature Drosophila sperm were treated with several doses of 0.68 Mev neutrons or X-rays and the frequency of translocations, recessive lethal mutations, and dominant lethal mutations measured. It was found that: translocations increase linearly with increasing neutron dose; translocations induced by X-rays increase with a power of the dose greater than 1; the RBE for translocations varies from 4.0 at low dose to 2.2. at high dose; both X-ray-induced and neutron-induced recessive lethal mutations increase linearly with dose; the RBE for recessive lethal mutations is 1.8; the neutron survival curve has no shoulder; the X-ray survival curve has a slight shoulder; and the RBE for the straight portion of these curves is about 3.6.

5.0527, INTERACTION OF THERMAL AND RADIATIVE PROCESSES IN BIOLOGICAL SYSTEMS
H.A. JOHNSON, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-1)GEN-16)

The existence of the interaction of thermal and radiative processes in biological systems is well known but very little is known of the mechanisms involved. It is planned to thermally inactivate enzymes, both crystalline and in solution, in the presence of ionizing radiation in order to measure changes in the activation energy for protein inactivation which may be brought about by the presence of ionizing radiation, and to determine the extent to which thermolabile sites on a molecule correspond to radiation labile sites.

Specifically, horseradish peroxidase in solution and in the form of dry crystals is to be irradiated in the high intensity radiation laboratory in water jacketed vessels which are carefully temperature controlled. The enzyme will then be tested for specific action on hydrogen peroxide using colorimetric tests. Arrhenius plots of rate of inactivation and temperature will give the resultant activation energy. With a knowledge of the dose to an enzyme molecule, it should be possible to estimate what fraction of the absorbed dose appears at a thermolabile site and contributes to the thermal inactivation.

A theoretical relationship between thermal and radiation effects at the molecular level has been derived. (Rad. Res. 32; 663, 1967).

Small doses of radiation (100r) greatly decrease the stability of peroxidase in solution. The radiation induced change in activation energy for thermal inactivation has been measured. The influence of radiation dose, quality of radiation, and enzyme concentration on this phenomenon have been determined.

5.0528, HEMOGLOBIN BIOSYNTHESIS
J.R. KLEIN, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

Emphasis in this work is upon the regulation of heme and globin synthesis and associated processes such as the direct incorporation of plasma iron into heme and the metabolism of non-heme protoporphyrin. Search for regulatory factors involves tests for effects of irradiation, drugs, and other materials on the syntheses and processes. At present, particular attention is being paid to normal hemoglobin heterogeneity, a phenomenon common to all animal species, but little understood. The main experimental system employed is the Pekin duck erythrocyte which synthesizes considerable hemoglobin in the circulation and 'in vitro' and has a conveniently short life span. The erythrocytes of the adult animal contain two distinct and readily separable hemoglobins.

Results: The two adult duck hemoglobins were found to differ in amount within the erythrocytes, in amino acid compositions of the constituent globin, and in rate of synthesis 'in vitro'. Limited evidence for segregation of the hemoglobins within different erythrocytes was obtained. The system giving rise to one of the hemoglobins is more affected by irradiation of the animal than the other.

5.0529, EXPERIMENTAL RADIATION CARCINOGENESIS
C.V. ROBINSON, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

Certain effects of radiation at the animal level can reasonably be assumed to depend directly on the radiation response of only a single critical cell type - for example, the acute hemopoietic syndrome on the response of the hemopoietic repopulating or stem cell, and radiation- induced leukemia on the delayed response of a cell type as yet unidentified. In such instances it appears feasible to relate, by means of a mathematical model, the animal and the cellular dose effect curves. In general, account must be taken not only of the primary radiation response of cells of the critical type, but of the proliferation which they initiate, and the animal's requirement for, or sensitivity to, their progeny. Of use in the analysis are; the theory of random variables and stochastic processes, Fourier transforms, computer simulation, and the theory of competing risks. Plans for future work are concerned with: 1) radiation-induced leukemia, 2) effects of dose protraction on the width of the animal dose-survival curve as well as on the mean lethal dose, and 3) extension of a presently-completed model of the hemopoietic syndrome and comparison of it with new data as it becomes available.

Results to Date: Progress to date includes: 1) the above-mentioned model of the hemopoietic syndrome and comparison with published data on the mouse; 2) a theory of the effect of nonuniformity of dose distribution on the hemopoietic syndrome; 3) partial completion of a theory of an effect of dose protraction on the width of the animal dose- survival curve when the mean lethal dose is not affected; and 4) partial completion of an analysis of published data on the incidence of three classes of radiation-induced leukemia in mice, utilizing the theory of competing risks, on which a model is to be based.

5.0530, CORRELATION OF RADIORESISTANCE WITH HEMOPOIETIC PARAMETERS IN MICE
C.V. ROBINSON, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

The curve of acute (30-day) mortality vs dose for animals dying of hemopoietic failure postirradiation, may be characterized by the median (50%) lethal dose, the LD50' and a parameter measuring curve 'width', such as the difference LD84 minus LD16. Expression of each of these in terms of mean values and variances of hemopoietic cellular parameters affords a mathematical model, the experimental testing of which is expected to provide further insight into the cellular basis of animal radioresistance. Some of the required cellular parameters may be measured relatively directly, while others must be estimated from measurable quantitites. Measurements are expected to include, for example, blood counts, blood volume determinations, assay of bone marrow for repopulating capacity, and the effect on this

capacity of different doses of radiation to the donor and to the recipient. A study is in progress with a radiosensitive strain of mice and a moderately radioresistant one, which seeks to account for the difference in radioresistance in terms of the model. As further data become available for comparison, extension and modification of the model may be required.

Results to date: Preliminary work has been completed on female mice of two strains chosen for comparison and housed together from age 5 weeks. A satisfactory magnitude and reproducibility were found for the difference in LD50, 30 days, of X-ray at 17 weeks, the age chosen for comparison. Additional LD50, 30-day, values at 14 and 20 weeks of age showed an acceptable rate of change in this age range. Values of the LD50, 5 days, determined at 17 weeks were found to be greater than the corresponding 30-day values by at least 450 R, confirmatory evidence for a relatively pure hemopoietic syndrome for each strain following doses in the 30-day lethal range.

5.0531, EXPERIMENTAL RADIATION CARCINOGENESIS

C.J. SHELLABARGER, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

The objective is to study basic mechanisms of radiation carcinogenesis using primarily the relatively large and relativey rapid mammary neoplastic response of the female rat to ionizing radiation. This particular model has been selected for studies of radiation carcinogenesis because a large body of data concerned with the neoplastic response of rat mammary tissue has been accumulated, the model system lends itself to meaningful experimentation, and the animal model appears to be reasonably close to the human situation. In general, young, female rats are exposed to a single sublethal dose X-radiation and the development of mammary neoplasia is followed for a one-year period. These data serve then as a base line for comparison with data obtained by experimental radiations. Experimental radiations include: fractionation and protraction; various dose-rates; and various qualities of LET.

Results: An experiment completed, indicated that 400 R of X- irradiation given in 2 equal fractions at intervals of 0, 2, 6,or 24 hours produced incidences of mammary neoplasia that were not different among the 4 irradiated groups. Incomplete data from experiments not yet finished suggest that exposure at 24 days of age produces a mammary neoplastic incidence somewhat smaller than when animals were exposed to the same dose at 42 or 84 or 225 days of age. Other incomplete experiments suggest that mammary neoplasia can occur in transplanted mammary tissue that was irradiated 'in vitro', and that the Lewis strain is somewhat less sensitive than the Sprague-Dawley strain.

5.0532, STUDIES ON THE EFFECT OF NEUTRON IRRADIATION ON SEEDS

H.H. SMITH, Brookhaven Natl. Lab., *Upton, New York* 11973

Studies on the effect of neutron irradiation on seeds (part of a coordinated program of research on the use of neutrons in seed irradiation).

SUPPORTED BY Intl. Atomic Energy Agency - Austria

5.0533, STUDIES ON THE EFFECT OF NEUTRON IRRADIATION ON SEEDS (ABBREV)

H.H. SMITH, Brookhaven Natl. Lab., *Upton, New York* 11973

The general objective of this research is to investigate the relative biological effectiveness (RBE) in plants of radiations of different linear energy transfer (LET). The materials irradiated are dry seeds of various plant species, particularly maize and Arabidopsis, and the main irradiations used are fast (fission) neutrons, and other high LET radiations, the effects of which are compared with those of 250 kVp X rays (low average LET). The responses measured are the frequency of induction of specific nonlethal somatic mutations, tumor formation, isozyme multiplicity and various criteria of cell lethality. Results have shown a maximum RBE at LET's of 72 to 174 KeV/mu; these RBE's are generally high (around 30 to 100 depending on dose and other factors) and the sensitive sites damaged to produce these effects are of the order of thickness of DNA molecules.

5.0534, RADIATION CYTOGENETICS OF HIGHER PLANTS

H.H. SMITH, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

The purpose of these investigations is to compare the relative biological effectiveness (RBE) of different types of ionizing radiations on cytogenetic systems of higher plants. The effects of monoenergetic neutrons, mesons, high energy protons, and heavy ions (He4 to Ar40) are being compared with the better known effects of X and gamma rays. The materials used are primarily special genetic stocks of maize and 'Arabidopsis', but are being extended to include a wide variety of plant species. The main procedures followed are to irradiate dry seeds under rigidly controlled environmental conditions and to observe the frequency of induced nonlethal somatic mutations as well as various criteria of cell lethality. Current emphasis will be on developing a mathematical model for the relation between a specific locus somatic mutation and cell lethality in maize which will take into account the number of cells at risk, the fraction of the genome involved in the mutation, the number of chromosome breaks causing cell lethality and the multiplicity of breaks attributable to a neutron.

Results: Results with Arabidopsis seeds irradiated with accelerated heavy ions and scored for tumor induction, growth inhibition, and somatic mutation showed the same variation pattern in RBE throughout the range in LET (from 2 to 1890 KeV mu. The RBE maximum, which reached 30, was highest at 72 to 174 KeV mu. Cross section analysis indicated that the sensitive sites for the 3 effects studied each had effective thicknesses of a few angstrom units to a few tens of angstrom units, which is consistent with a DNA target.

5.0536, PREDICTIONS OF RADIOSENSITIVITY IN HIGHER PLANTS

A.H. SPARROW, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

The amount of radiation that can be tolerated by an organism is determined by many factors. The purpose of this work is to determine experimentally the radiation sensitivities of many species and to relate these to nuclear or chromosomal factors in such a way as to enable the prediction of radiobiological responses of other plant species to various amounts, dose rates and kinds of radiation. An index of nuclear and chromosome volumes, chromosome numbers, DNA content, duration of mitotic cycle and energy absorption per chromosome for many species of plants and animals is being assembled.

Results: Radiation sensitivity, as measured by chromosome aberration, mutation rate, survival, growth inhibition, yield and pollen abortion, has been related to interphase chromosome volume and DNA content per chromosome. From the regression lines obtained, predictions can be made of the radiosensitivity of herbaceous or woody plants if the interphase chromosome volume or DNA content per chromosome is known. Woody forms are more sensitive than herbaceous forms of similar chromosome size and, in general, gymnosperms tolerate less exposure to radiation than angiosperms. Many gymnosperm species have predicted or actual LD50s below 1000 R and as a group are much more sensitive than most angiosperms. Predicted LD50s and/or doses required to reduce yield by 50% have been obtained for several

hundred species of higher plants including many species of economic importance. Plants vary in sensitivity with stage of development. Dry seeds of any given species are most resistant, immature growing plants intermediate and reproductive stages the most sensitive. Effects on somatic cells are more uniform and easier to predict than effects on reproductive (meiotic) stages.

5.0537, RADIOSENSITIVITY OF ANTIBODY RESPONSES ELICITED WITH COMPLEXES OF ANTIGEN AND ANTIBODY

R.D. STONER, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

Sublethal doses of cobalt-60 ionizing radiation as low as 100 to 400 rads increasingly repress and/or abolish antibody responses in mice and render animals more susceptible to infection. It is the purpose of this study to develop more effective means for successful immunization of irradiated animals. Our previous findings have demonstrated enhanced primary antibody responses in both normal and irradiated mice (400 rads) when immunization is accomplished with fluid tetanus toxoid (FTT) in complex with specific mouse antibody. Emphasis will be directed to the immunogenicity of complexes of FTT and IgG globulins prepared from specific mouse, rabbit and human antitoxin. A continuing phase of the study deals with the radiosensitivity of primary and secondary antibody responses to various types of ionizing radiations. An average RBE of 2.5 for 2.2 Bev protons was found for primary antitoxin responses and an RBE of 1.5 was obtained for secondary responses in comparative experiments with X- and gamma-radiations. In view of these findings, it would be desirable to extend these experiments to include the effects of fission neutrons on antibody responses to FTT, as commonly used in man, and to FTT given in complex with specific antibody.

Results: Irradiated mice (400-500 rads) recovered their capacity to respond to antigenic stimulation earlier (8-10 days) when FTT was given as a complex formed in antigen excess or at equivalence. When the same amount of FTT, as well as 10 times the dose, was given alone it was not possible to achieve primary immunization in irradiated animals. Enhanced primary antitoxin responses were also obtained when mice were primed with an FTT complex formed at equivalence and radiation (400 rads) was delivered one hour prior to a second injection of FTT on days 3, 6, 9 and 12 after primary immunization. In general the irradiated animals produced higher titers of antitoxin than control animals.

5.0538, RADIATION RECOVERY MECHANISMS OF G1 AND G2 CELLS IN THE MITOTIC CYCLE OF PISUM ROOT MERISTEMS

J. VANTHOF, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

The meristematic and embryonic cell long recognized as highly radiosensitive continues to remain enigmatic as to the basis of the hypersensitivity. At present, it is clear that two major functions of a dividing cell are affected. These are mitosis and DNA synthesis. The guiding hypothesis of the project is that ionizing radiation affects the mechanisms responsible for the regulation of mitosis and DNA synthesis and damages DNA itself. This implies the possible existence of two types of recovery mechanisms: one concerned with regulatory mechanisms and another with DNA repair. Recent evidence has demonstrated that the radiosensitive regulatory mechanisms are active before the onset of either DNA synthesis or mitosis and therefore take place in the G1 and G2 periods of the cycle; DNA repair presumably may take place throughout most of interphase. Most experimentation is conducted with excised pea root meristems in which DNA synthesis and mitosis are absolutely controlled. Analyses are performed primarily on the cellular and molecular levels utilizing radioisotopes, autoradiography, scintillation counting and density gradients.

Results: Experiments with G2 cells showed (1) that their capacity to complete one postirradiation mitosis and (2) that mitotic delay recovered in the absence of progression through the mitotic cycle. The kinetics of recovery suggested that each parameter reflected damage to different cellular systems. Inhibition of scheduled DNA synthesis with 5-fluorodeoxyuridine did not, while hypoxia did, prevent recovery from irradiation damage.

5.0539, ENVIRONMENTAL BIOLOGY - EFFECTS OF IONIZING RADIATION ON TERRESTRIAL ECOSYSTEMS

G.M. WOODWELL, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

Two principal field experiments have been established to provide comparative data on radiation effects from different ecosystems: one an herbaceous field characteristic of the early stages of succession following land abandonment; the second a forest, late in the succession. Structure is measured through a detailed inventory of the plant populations, an inventory which includes various estimates of plant condition and growth. This inventory, used with correlations to predict weight of plant parts, provides an estimate of living and dead standing crop at any time. Detailed studies of function use these data.

Results: From this work it is clear that: (1) there is a difference of between 5- and 10-fold in the sensitivity of field and forest, the forest being the more sensitive; (2) that this difference indicates a general trend, at least within the eastern part of North America: the early stages of plant succession are radioresistant, later stages more sensitive; (3) that this difference in the sensitivity of plant communities to radiation may parallel other environmental gradients, an observation that suggests a relationship between certain aspects of the ecology of plant: and their susceptibility to radiation; (4) that diversity is a more sensitive index of radiation damage to a plant community than any index incorporating abundance or density; and (5) that gradients of radiation intensity tend to sort species in natural communities according to several characteristics including stature (low-growing plants being resistant), chromosome size, and ploidy.

5.0540, ENVIRONMENTAL INTERACTIONS

D.W. ENGEL, U.S. Dept. of the Interior, Bureau of Commercial Fisheries, *Beaufort, North Carolina* 28516 (AT(49-7)-5)

Effects of ionizing radiation on estuarine organisms are influenced by environmental conditions. Thus, our investigations of the effects of ionizing radiation fall into two categories: (1) the effect of interactions between radiation, temperature, and salinity on osmoregulation of the blue crab, Callinectes sapidus; and (2) the effect of continuous low levels of gamma irradiation on the survival, population growth, and physiology of estuarine organisms. The blue crabs used in these experiments will be subjected to a range of temperatures (12-28 degrees C.), salinities (5-35 p.p.t.), and radiation doses (5,000-40,000 Rads). Two types of experimental procedures will be used. First, the survival of crabs at various temperature-salinity- radiation combinations will be tested. Second, the effects of temperature-salinity-radiation combinations on osmoregulation will be followed. The osmoregulatory capabilities of the crabs will be determined by measuring levels of inorganic ions and free amino acids in the hemolymph. The effects of continuous low-level irradiation will be tested using three types of communities: (1) fouling community succession on a solid substrate, (2) estuarine microcosms, and (3) unicellular algal populations. All of the experiments will be designed so that the dose rates will range from 4.0 to 0.11 R/hr. The actual procedure for each community will vary with the community which is being investigated.

Results: The investigation of the influence of environmental factors on the radiation response of estuarine organisms has demonstrated that salinity and temperature interact with radiation to affect the survival and physiological balance of the estuarine fish, the mummichog. It also has been established that there is a wide range of radiation sensitivities among decapod crustacea (LD50-40 days for grass shrimp, 215 Rads, and for blue crabs, 42,000 Rads). Part 2 of 3.

5.0541, THE EFFECTS OF RADIATION ON THE PHYSIOLOGY OF MARINE ORGANISMS (A COOPERATIVE AGREEMENT WITH THE ATOMIC ENERGY COMMISSION)
D.W. ENGEL, U.S. Dept. of the Interior, Bureau of Commercial Fisheries, *Beaufort, North Carolina* 28516

Ionizing radiation has always been a part of the natural environment; however, the advent of the atomic age has increased the amount of radioactivity in the environment. The marine environment is subject to possible radioactive contamination from the growing numbers of reactors as well as from fallout and waste disposal. Though it is known that marine organisms tend to concentrate radionuclides, very little is known about the effects of ionizing radiations on these organisms. A more complete understanding is needed of species sensitivities to radiation and specific physiological effects of acute and chronic exposures. This information will aid in predicting effects from radioactivity in the environment and in applying controlled irradiation to eradicate undesirable species or to breed desirabie species that are more resistant to environmental stresses. The purpose of this project is to describe the effects of acute and chronic doses of radiation from both internal and external sources on the physiology of marine organisms.

The effects of radiation may be death or alteration in some physiological or metabolic activity. In this investigation, LD-50's will be used to describe species sensitivity to radiation under varying conditions; while blood components, hematopoietic tissues, and respiration rates of whole organisms of tissues will be used as indices of radiation effects.

Sources of radiation will be by Cobalt-60 irradiators, an X-ray machine, labeled food, and administered radionuclides. Standard hematological and manometric techniques will be used to measure the various parameters. The marine teleost fishes used in this project will include Opsanus tau, Paralichthys sp., Pomatomus saltatrix, and Scomberomorus maculatus. The project will also encompass representatives of other groups of marine organisms.

5.0542, EFFECTS OF IONIZING RADIATION ON PLANT SPECIES, POPULATIONS AND ECOSYSTEMS
J.F. MCCORMICK, Univ. of North Carolina, Graduate School, *Chapel Hill, North Carolina* 27514 (AT(40-1))

The objectives of this project are to analyze the effects of gamma and beta radiations upon natural communities and upon populations of species which dominate these ecosystems. Herbaceous old fields have been exposed to gamma radiation for one month during each of four seasons in order to estimate the influence of season on radiation sensitivity. Results of a summer exposure of a pine forest to the same 9200 curie 137Cs source have been published. Results of a similar study in a tropical rain forest have been accepted for publication. The sensitivity of dominant species of these ecosystems (pine seedlings, old field weeds, palm trees) has been analyzed in the controlled environment laboratory and results are ready for publication. A study of radiostrontium cycling in a pine forest was also completed. Studies of the effects of beta radiation and simulated fallout upon a natural community have been initiated. Investigations of community structure, factors controlling structure, and community metabolism including carbon, energy, and water budgets have been completed. These natural granite outcrop communities were exposed to simulated fallout and beta radiation in the summer of 1969.

Results to date: Herbaceous old field communities are among the most radiation resistant terrestrial ecosystems. Radiation sensitivity varies with season and ecological factors greatly modify radiation sensitivity as estimated in the laboratory. The rain forest is more resistant to radiation than temperate forests studied. The pine forest is the most sensitive forest system studied and most coniferous forests would be destroyed in the event of a nuclear war.

SUPPORTED BY U.S. Atomic Energy Commission

5.0543, RECOVERY OF A PINE FOREST FOLLOWING EXPOSURE TO IONIZING RADIATION
J.F. MCCORMICK, Univ. of North Carolina, School of Arts, *Chapel Hill, North Carolina* 27514 (AT-(40-1)-3299)

In August, 1964 a 12 year old forest of loblolly and slash pine at the Savannah River Plant was exposed to 9200 curies of Cs137 for one month. All pines which received 3000R or more were killed and trees less than 5 ft. tall were killed by 500R or more. Herbaceous weed species invaded the opened forest area immediately and succession has followed an apparently normal pattern but at an unusually fast rate ever since. During the next year it is proposed to initiate quantitative analyses of community composition, tree growth, and analysis of seed and seedlings from irradiated parent trees.

Results: Approximately 3000 trees are identified with tags and pre and post radiation growth data are available. We have published the descriptions of damage produced and initial recovery during the year following irradiation of the forest. Now we wish to examine recovery during the subsequent 5 years. Part 1 of 6.

5.0544, RECOVERY OF A TROPICAL RAIN FOREST FOLLOWING EXPOSURE TO GAMMA RADIATON
J.F. MCCORMICK, Univ. of North Carolina, School of Arts, *Chapel Hill, North Carolina* 27514 (AT-(40-1)-3299)

In 1964 studies of seedling diversity and abundance were initiated in the El Verde forest with the idea that quantitative analyses of seedling populations would be a sensitive measure of radiation effects and more importantly, would serve as a means of predicting and measuring recovery since it would be seedlings which would produce the post radiation forest. It was predicted that 'Palicourea riperia' would be an important ground and shrub species following radiation as well as normal successional species such as 'Cecropia.' Permanent quadrats and sampling areas corresponding to the grid established for other studies have been censused three times since irradiation.

Results: The recovery pattern is as predicted. The canopy is dominated by 'Cecropia' and the shrub layer is a dense population of 'Palicourea'. It is unfortunate that the research papers describing these changes and the predictions were not permitted to be published or were delayed in publication. Part 2 of 6.

SUPPORTED BY U.S. Atomic Energy Commission

5.0545, RECOVERY OF A NATURAL PLANT COMMUNITY FOLLOWING EXPOSURE TO BETA RADIATION FROM SIMULATED FALLOUT PARTICLES
J.F. MCCORMICK, Univ. of North Carolina, School of Arts, *Chapel Hill, North Carolina* 27514 (AT-(40-1)-3299)

A natural plant community was exposed to beta radiation in the form of yttrium-90 coated fallout particles of 44 micron diameter. Specific activity was 4.74 mc/g and 10g/sq ft was evenly dispersed over granite outcrop communities measuring 20 sq ft in area to give average doses of 7000 rads over the following month. Community structure changed considerably due to death of terminal buds, reduced internode elongation and compensatory acceleration of lateral shoot growth in the dominant species 'Viquiera porteri'. Community metabolism did not change due to homeostatic adjustments in the physical structure of the community. Reproduction was affected via reduced and delayed germination of seed from apparently mutant flower heads. Species density, distribution, biomass, growth, diversity and reproduction will be analyzed during the next year in order to understand ecosystem recovery.

Results: A combination of beta bath and beta contact dose of 7000 rad inhibited reproduction, altered physical structure, but did not affect metabolism in a natural plant community exposed to 10 g/sq ft of simulated fallout particles having a specific activity of 4.74 mc/g. Part 3 of 6.

SUPPORTED BY U.S. Atomic Energy Commission

5.0546, GENETIC EFFECTS OF ACUTE BETA IRRADIATION FROM SIMULATED FALLOUT PARTICLES UPON NATURAL POPULATIONS OF VIGUIEPA PORTERI
J.F. MCCORMICK, Univ. of North Carolina, School of Arts, *Chapel Hill, North Carolina* 27514 (AT-(40-1)-3299)

Natural populations of 'Viguiera porteri' grown in the North Carolina Botanical Garden were treated with simulated fallout particles with a mean diameter of 44 microns and a specific activity of 4.74 mc/g. Beta bath doses and contact doses from the yttrium-90 coated particles averaged 7000 rads and reached maximum levels of 11,000 - 13,000 rads over one month. Two types of aberrant flower heads resulted, one apparently the result of somatic cell death and the other the result of a mutation in bud primordia. Seed from the latter type exhibited delayed and reduced germination. These seeds are being planted and two succeeding generations of these populations will be examined for mutant and aberrant growth and reproduction. All populations, those from normal flowers and seeds, those from heads which suffered somatic cell death, and those from apparently mutant flower heads are being grown in the North Carolina Controlled Environment Laboratory.

Results: Results revealed that the only seed which suffered delayed or reduced germination were those from flowers with more than the normal number of ray flowers. This aberrant type occurs with 3% frequency in normal populations and 60% frequency in the populations exposed to 7000 rads of beta radiation from fallout particles. Time required to germinate was doubled and percent germination was reduced by 30%. Part 4 of 6.

5.0547, THE NATURE OF RADIATION SENSITIVITY IN PINES
J.F. MCCORMICK, Univ. of North Carolina, School of Arts, *Chapel Hill, North Carolina* 27514 (AT-(40-1)-3299)

The radiation sensitivity of pine species can not be explained on the basis of the 'target theory' or 'nuclear volume' theory as can the radiation sensitivity of most plant species and many animal species. As in man, the response of pine species to radiation is a response to a complex set of conditions rather than to a single isolated stimulus. The hypothesis is presented that pines suffer from both the direct effects of radiation and simultaneously from indirect effects due to the production of ozone in air by ionizing radiation. Factorial analysis of pine species responses to varying levels and combinations of ozone and gamma radiation are underway. Pines are not only one of the most radiation sensitive groups of plants, but they are also one of the most ozone sensitive plant species.

Results: Results are limited to literature review, acquisition of equipment, design of the test system and formulation of the hypothesis offered above. Experimental results will be obtained within the following year. Part 5 of 6.

SUPPORTED BY U.S. Atomic Energy Commission

5.0548, EFFECTS OF GAMMA RADIATION ON HERBACEOUS SPECIES IN A NORTHERN HARDWOOD FOREST
J.F. MCCORMICK, Univ. of North Carolina, School of Arts, *Chapel Hill, North Carolina* 27514 (AT-(40-1)-3299)

Field census data and results of laboratory germination and growth studies are being used to describe the population dynamics of two important herbaceous species in the northern hardwood forest, 'Cornus canadensis' and 'Aster macrophylla.' Actuarial life tables and survivorship curves, similar to those insurance companies use to establish insurance rates, will be constructed in order to quantitatively describe population vitality and to predict future vitality. Following irradiation of the experimental site near Rhinelander, Wisconsin, the same type of data will be obtained to measure changes following irradiation. Reproduction, growth and metabolism are characteristics of particular importance which are being analyzed in the field, in the controlled environment laboratory and in the gamma field at Rhinelander.

Results: Both species reproduce asexually from underground stems as well as sexually. Sexual reproduction is primarily in open disturbed environments similar to conditions expected following irradiation. Asexual reproduction predominates. Both species should be important in ecosystem recovery from 5 months irradiation in 1971. Both species should increase in sexual reproduction following destruction of the forest canopy and both should survive in the irradiated forest due to the protected nature of underground meristems. Part 6 of 6.

5.0549, COMPARATIVE EFFECTS OF TWO RADIATION EXPOSURE REGIMES
D.G. WILLHOIT, Univ. of North Carolina, School of Public Health, *Chapel Hill, North Carolina* 27514

The cell cycle parameters of intestinal crypt cells of mice are to be characterized for testing a dose-fractionating and dose-rate model developed previously on this project. Indications are that dose fractionation effects on animal survival time are compatible with a model based on intracellular repair and cell progression. Dose-rate effects, likewise, can be explained by a three component model consisting of terms for single-event inactivation, multiple-event inactivation, and repopulation due to cell division. Studies of dose- rate and dose fractionation on spleen colony formation are to be studied also to provide additional data to test the models.

5.0550, THE EFFECT OF RADIATION ON MUCOSAL PHOSPHOLIPASE ACTIVITY
F. BERNHEIM, Duke University, School of Medicine, *Durham, North Carolina* 27706 (AT(40-1))

The objective of the proposed research will be to investigate the effect of cytostatic agents and X-irradiation on the eosinophilic leukocytes of the bone marrow and intestine and to correlate these effects with variations in the phospholipases (lecithinase, phospholipase B) of these tissues. The background for this approach comes from the observation that a direct relationship between the number of the eosinophilic leukocytes and the enzymes exists for the spleen, uterus, peritoneal fluid and bone marrow of the rat. In the latter organ a relationship to the maturation process of these cells is indicated. Drugs to be used singly or in combination include bone marrow depressants, corticosteroids, epinephrine, protein synthesis inhibitors.

Results: A quantitative relationship between the number of eosinophilic leukocytes and the content in phospholipase B has been established for the spleen, uterus, peritoneal fluid and bone marrow of the rat. In these organs, a sharp decline in phospholipase activity and eosinophilic leukocyte population occurs after administration of cytotoxic drugs or exposure to 600 r whole body X-irradiation. The dependence of tissue levels of the enzyme upon the state of activity of the bone marrow is indicated.

5.0553, DNA REPAIR IN LYMPHOCYTES

A.T. HUANG, U.S. Veterans Administration, Hospital, *Durham, North Carolina* 27705

Over the past two years we have been very interested in the study of chronic lymphocytic leukemia leukocytes because of their increased lymphocyte counts with a normal DNA replication rate. Previously, we have demonstrated that in 15 patients with chronic lymphocytic leukemia studied for cellular DNA repair, a 16-fold enhancement of repair was found as compared to that of 9 normal individuals. This work was presented at the American Hematology Society meeting in Cleveland, Ohio in December 1969.

In collaboration with doctors R.B. Setlow and W.L. Carrier of Biophysics Section, Biology Division, Oak Ridge National Laboratory, we have further defined that the increased repair is due to an increased rate of excision of the DNA lesions by the leukemic lymphocytes.

This year, we propose to investigate the repair from damage caused by ultraviolet light at 254 nm and from X-ray and chemical agents. We will measure the rate of removal pyrimidine dimers from the UV- irradiated DNA as a measurement of DNA repair in various leukemias to compare with the normal lymphocytes. We will measure the recovery of the lymphocytes from X-ray and chemical damage by measuring the changes in molecular weight through alkaline sucrose gradient sedimentation. Currently, with the use of the blood cell separater, we were able to obtain leukemic lymphocytes in large amounts. The cells obtained through this method will be used in the assay and purification of the UV-specific endonuclease. This particular enzyme is essential for the initiation of DNA repair which has been purified in bacteria but not mammalian cells.

5.0554, RADIATION GENETICS AND RADIATION RESISTANCE IN PEANUTS

D.A. EMERY, Univ. of North Carolina, School of Agriculture, *Raleigh, North Carolina* 27607 (AT-(40-1)-1747)

Three investigations are in progress designed to improve mutation breeding methodology through (a) evolutionary plant breeding techniques using re-irradiation and bulk populations to enhance natural selection, (b) demonstrated comparisons of yield potential in large hybrid populations including both pre and post hybrid treatments with irradiation and (c) the early estimation of heterosis and combining ability in macro-mutant and macro-mutant x control hybrid populations exposed to a range of temperature treatments. The cultivated peanut is the test organism. Experiments will be conducted in both the field and phytotron.

RESULTS: Test populations have been developed to evaluate the progress via natural selection in the control and irradiated bulk populations of diverse lines of cultivated peanuts. Statistically significant interactions between macro-mutant and temperature were noted when seven macro-mutants and the unirradiated control were exposed as seedlings to temperatures ranging from 22 degrees C to 34 degrees C. Interrelationships among the 12 characters used in the assessment have also been determined.

5.0555, FUNDAMENTAL INVESTIGATIONS IN RADIATION POLYMER CHEMISTRY

V.T. STANNET, Univ. of North Carolina, School of Engineering, *Raleigh, North Carolina* 27600 (DA)

Technical Objective: Polmerization and copolymerization studies at high dose rates will be conducted. The proposed research has promise of contributing information needed by the Army both in the field of polymer chemistry and in radiation chemistry. Specifically, new materials may be generated and the behavior of materials exposed to radiation will be studied, such research should provide information on the stability of the properties of materials exposed to radiation.

5.0556, TIME-RADIATION DOSE RELATIONSHIPS TO BIOLOGIC DAMAGE

R.L. WITCOFSKI, Wake Forest University, School of Medicine, *Winston Salem, North Carolina* 27103

We are attempting to determine whether there is a time-dose relationship in the response of a biologic system to radiation delivered by clinically important radionuclides. The use of ever shorter half- lived radionuclides in nuclear medicine is based on the concept that a somewhat larger amount of short-lived radionuclides can be given to patients than is possible with longer-lived radioisotopes yielding both better diagnostic tests and less total radiation dose. The regenerating rat liver was proposed as a model system to test the effectiveness of these radiations. Replicate experiments using closely matched untreated animals have demonstrated great variability among animals killed at the same time as well as variability between experiments when DNA synthesis and mitosis were studied. A dose of 500 rads during the early stages of regeneration only reduced the levels of DNA synthesis whereas it completely inhibited mitosis. A dose of 250 rads results in reduction in levels of mitosis but does not completely inhibit mitosis.

5.0557, BIOLOGICAL EFFECTS OF LOW VELOCITY ELECTRONS

G.S. SPERTI, Inst. Divi Thomae, *Cincinnati, Ohio* 45206

The previous studies on the effects of 100-1000 volt electrons on the activity of trypsin (on TAME as substrate) will be extended to try to determine the nature of the 300 volt activation (using electrophoresis, thin layer chromatography, and spectroscopy) with particular attention to the two components observed in the trypsin. The inactivation at higher voltages will also be studied, particularly in terms of breakage of disulfide bonds, and compared with ultraviolet inactivation. The relative sensitivity to electron bombardment of sulfhydryl-dependent enzymes (such as glyceraldehyde-3-phosphate dehydrogenase) will also be investigated in view of the fact that trypsin and catalase, which have been studied, are not sulfhydryl- dependent.

5.0558, STUDIES ON THE MECHANISM OF THE EFFECT OF IONIZING RADIATIONS ON THE OLFACTORY SYSTEM

G.P. COOPER, Univ. of Cincinnati, School of Medicine, *Cincinnati, Ohio* 45221 (AT(11-1)-1669)

Three experiments are proposed which are aimed at identifying the radiation-produced olfactory stimulus and at examining possible deleterious effects of X-ray and ozone on other mucous membranes of the respiratory tract: (1) In experiments with rats response of olfactory bulb neurons to X-ray, ozone, and odor will be compared to determine whether ozone or a similar agent is the radiation-produced stimulus. (2) The spatial-avoidance test, in which rats show a preference for the shielded, unirradiated half of a test chamber, will be used to determine (a) whether olfactory

stimulation serves as a conditional stimulus, (b) whether the olfactory stimulus is a neutral one or is noxious, and (c) whether ozone in the test chamber will mask the effects of X-ray so that rats fail to condition. (3) In experiments with guinea pigs, the known capacity of ozone to potentiate histamine-induced respiratory distress and death will be used to advantage. Animals will be exposed to X-ray, ozone, or X-ray and ozone to determine whether the effects of x-ray and ozone are similar and if so whether their effects are additive.

The response of olfactory bulb neurons to X-rays is constant for nasal oxygen concentrations from 100 per cent down to about 2 per cent. Below 2 per cent the response diminishes significantly. Responses to odor are little affected by changes in nasal oxygen concentration.

Lightly anesthetized and unanesthetized rats show immediate acceleration of respiratory rate upon exposure to X-rays. Olfactory stimulation by X-rays is mainly responsible since rats with olfactory bulb ablations do not respond.

5.0560, RADIATION EFFECTS ON CELL AND POPULATIONS DYNAMICS OF U-12 FIBROBLASTS
H.L. FRIEDELL, Case Western Reserve Univ., School of Medicine, *Cleveland, Ohio* 44106 (W-31-109-ENG-78)

The population dynamics of synchronized strain U-12 mammalian cells is being investigated from the point of view of the various activities of single cells, such as division, division failure, division delay, giant cell formation or cell death and the time distribution of these activities after low doses of ionizing radiation, measured through the use of time lapse photomicrography. Detailed population growth curves are being determined in order to obtain population measures of the radiation induced division delay, population doubling time, population deficit and fate of synchrony decay which can be compared with the averages of observations on individual cells. Studies on the effect of the shape of the interdivision time distribution on the log phase population doubling time are also being continued. Part 3 of 16.

5.0561, INVESTIGATIONS OF THE BIOLOGICAL EFFECTS OF RADIATION - A MULTI-DISCIPLINE APPROACH
H.L. FRIEDELL, Case Western Reserve Univ., School of Medicine, *Cleveland, Ohio* 44106 (W-31-109-ENG-78)

This is a broad, multi-disciplinary program of biomedical research aimed at the achievement of a better understanding of radio-biologic phenomena and the development of improved methods in nuclear medicine.

It includes studies in radiation physics, radiation biophysics, radiation biochemistry, radiation biology, modification of radiation response, and nuclear medicine. Major emphasis centers on the study of cell replication and the manner in which replicative activity is affected by ionizing and ultraviolet radiation.

A continuing effort is devoted to the development of new instruments for use in nuclear medicine, dosimetry, and radiological research. Part 1 of 22.

SUPPORTED BY U.S. Atomic Energy Commission

5.0562, RADIATION RESPONSE OF THE CELL MEMBRANE
H.L. FRIEDELL, Case Western Reserve Univ., School of Medicine, *Cleveland, Ohio* 44106 (W-31-109-ENG-78)

It is proposed that high doses of ionizing radiation can affect directly the permeability of the cell membrane to different molecules and ions, such as Na and K ions, while small doses (approx. 200 R) can affect the timing of a scheduled change in the state of the membrane; the effect of small doses is presumed to be the result of an altered rate of progression through the cell cycle in irradiated cells.

Synchronized mouse lymphoblasts (strain L5178-Y cells), which display cyclic oscillations of intracellular sodium and potassium, will be exposed to a large range of doses of ionizing radiations at different times during the cell cycle. The membrane permeabilities to Na and K ions will be observed following irradiation and compared with those in unirradiated cells. Part 7 of 16.

SUPPORTED BY U.S. Atomic Energy Commission

5.0563, COMPARISON OF RADIATION AND OXYGEN EFFECTS ON CELLS
H.L. FRIEDELL, Case Western Reserve Univ., School of Medicine, *Cleveland, Ohio* 44106 (W-31-109-ENG-78)

According to some investigators ionizing radiation and increased levels of oxygen have similar effects on biological materials, therefore, radiation studies will be combined with oxygen toxicity studies to determine whether there is a correlation between the morphological alterations caused by high levels of oxygen and by radiation. Work is now in progress to compare the effects of radiation and oxygen on cells using such parameters as nuclear and cell morphology, nucleolar morphology, generation time, and inhibition of the mitotic process. Part 12 of 22.

5.0564, THE RELATIONSHIP OF RADIATION SENSITIVITY TO ALTERATIONS IN THE DNA OF B. SUBTILIS
H.L. FRIEDELL, Case Western Reserve Univ., School of Medicine, *Cleveland, Ohio* 44106 (W-31-109-ENG-78)

We have previously detected two types of spores occurring during the sporulation-germination process of B. subtilis. These spore types differ in density, heat resistance, germination rate, and the properties of their DNA. We plan to investigate the order of appearance of the two spore types and study the changes in spore DNA structure and function with time during the sporulation process. Sensitivity of the two spore types to UV- and ionizing radiations will be correlated with changes produced in the spore DNA by the radiation.

We also plan to study the fate of irradiated donor DNA in the B. subtilis transformation system. Uptake into receptor cells, subsequent degradation, and recombination with receptor DNA will be determined and compared to results with non-irradiated donor DNA. The success of this investigation will depend largely upon our ability to obtain highly competent cultures of B. subtilis. Part 9 of 16.

5.0565, TRANSCRIPTION OF RNA & TRANSLATION OF ENZYMES DURING MITOTIC CYCLE OF PHYSARUM POLYCEPHALUM & RADIATION EFFECTS (ABBREV)
H.L. FRIEDELL, Case Western Reserve Univ., School of Medicine, *Cleveland, Ohio* 44106 (W-31-109-ENG-78)

We wish to demonstrate the synthesis of unique messenger RNA fractions at various times during the mitotic cycle of Physarum by use of hybridization competition experiments. So far, we have been unsuccessful in these attempts, possibly because of non-specific annealing of RNA fractions to regions of the DNA other than that from which they were transcribed. Conditions of hybrid formation will be varied to eliminate such non-

specific annealing if it occurs. If the synthesis of unique RNA fractions can be detected, we plan 1) to study the relationship of this synthesis to other cyclic events, 2) to determine whether irradiation inhibits the synthesis of one or more of these fractions, and 3) if such an effect can be related to the delay in mitosis caused by irradiation.

The time of transcription and translation of various specific step enzymes will also be determined throughout the mitotic cycle by measuring the effect of timed addition of inhibitors of RNA and protein synthesis on the increase of enzymatic activity. The plasmodia will then be exposed to ionizing radiation before, during, and after the transcription and translation processes with the objective of identifying the site of radiation damage. Part 11 of 16.

5.0566, PHASE 1 - FISSION PRODUCT METABOLISM AND RESPONSE IN LABORATORY AND DOMESTIC ANIMALS - FISSION PRODUCT STUDIES

F.W. LENGEMANN, Case Western Reserve Univ., School of Medicine, *Cleveland, Ohio* 44106 (AT(30-1))

The general objectives are to develop data relevant to coping with problems that may arise from radioactive contamination of the environment from any possible source. The main areas of study include: (a) expansion and refinement of models for prediction of intake commitments of radionuclides from milk (these are based on experimental data from cows, (b) metabolism of cesium and cerium in laboratory animals (c) prediction equations and metabolic patterns for strontium 90, (d) maintenance and ongoing evaluation of literature relative to environmental contamination.

Results: A generalized estimate of potential harm to man can be made based on the concept of the 'critical factors' and knowledge of metabolism and movement or environmental radiocontaminants in the biosphere. The need has become apparent, however, to consider special local conditions and attempt to estimate effects at low levels that may not be directly observable. Part 4 of 7.

5.0567, RADIATION-INDUCED MITOTIC DELAY

R.C. RUSTAD, Case Western Reserve Univ., School of Medicine, *Cleveland, Ohio* 44106 (W-31-109-ENG-78)

We have previously demonstrated that radiation damage to either the cytoplasm or some more sensitive component of the mitotic apparatus leads to division delay of sea urchin eggs and that gamma-ray damage to sperm is expressed differently in whole eggs and nucleate and enucleated half-eggs. Prefertilization and postfertilization recovery from gamma- ray damage leading to mitotic delay is inhibited with puromycin. Furthermore, we have discovered that prefertilization stimulation of protein synthesis 'cures' gamma-ray induced mitotic delay. Experiments will be performed to discriminate between the possibilities that this 'cure' reflects the synthesis of enzymes for recovery ('repairases') or the completion before fertilization of radiation-sensitive mitotic events. In addition, we will continue using puromycin to study the role of protein synthesis in the recovery from radiation damage during the mitotic cycle with special reference to 'unscheduled DNA synthesis' in HeLa cells. Part 4 of 16.

5.0568, STUDY OF THE LATENT EFFECTS OF GAMMA IRRADIATION ON HUMAN ENAMEL

R.L. MOSS, U.S. Veterans Administration, Center, *Dayton Ohio* 45428

The purpose of this study was to accumulate experimental evidence of the in vitro effect of controlled gamma radiation on extracted human teeth.

Progress: From contributing VA Hospitals, specimen have been collected from fourteen patients who were treated with gamma radiation therapy for neoplastic disease in or adjacent to the oral cavity. Specimen consist of assorted dentition taken from the patients several months post-radiation therapy. Most patients had clinical symptoms of 'radiation caries.'

Investigation for post-radiation enamel deterioration is made by immersion of specimen into a solution of radioactive isotope (S35) and gentian violet dye. Teeth are mounted in bioplastic and planoparallel serial sections are cut. Selected sections are submitted for auto- radiographs to determine isotope penetration into the enamel. Other sections are examined macroscopically to visualize dye penetration into the enamel. Autoradiographs and photographs of the specimen have been assembled.

Macroscopically, loss of peripheral surface layers of enamel is evident in many specimens. Dissolution of enamel surfaces is seen in areas that are not characteristically susceptible to the normal caries process. Structural alteration appears as a fairly uniform zone of surface porosity as demonstrated by both isotope and dye penetrations. Equivalent penetration is not seen in active carious lesions.

It is suggested that the surface porosity results after the elution of calcium and phosphorus from the hydroxapatite structure. Elution of these ions has been shown in a previous study of in vivo gamma irradiation of teeth.

Proposed direction of research: Project to be terminated. Manuscript in preparation.

SUPPORTED BY U.S. Veterans Administration

5.0569, EFFECT OF PH ON CALCIUM AND PHOSPHORUS DEMINERALIZATION OF IRRADIATED TOOTH ENAMEL

R.L. MOSS, U.S. Veterans Administration, Center, *Dayton, Ohio* 45428

Summary: This is a continuation of an ongoing study of the latent effects of irradition on human teeth. Data has been collected which demonstrates an alteration in the integrity of the enamel surface following exposure to gamma radiation. Laboratory investigation of postradiation enamel deterioration was made by immersion of specimen into radioactive isotope (S-35) and crystal violet dye. Autoradiographs and macroscopic photographs were made of serial planoparallel sections. Physical alteration of peripheral layers of enamel structure could be demonstrated in this clinical material.

Data was reported which indicated that in vitro radiation of teeth produed increased rates of enamel demineralization. It was shown that 250 KVP, 5000 r delivered in a single dose caused negligible changes in calcium and phosphorus elution rates over a 12-month period. Five- thousand r delivered in fractionated doses caused calcium and phosphorus elution at high rates.

Alteration of the pH in the postradiation oral environment has been implicated as contributory to the process of tooth deterioration. This project has been designed to study the in vitro effects of pH environments upon irradiated specimen. Calcium and phosphorus demineralization rates will be determined over a twelve-month period. Specimen will be compared with control and previous data for evidence of structural alteration.

Methods and Materials: A random specimen pool has been collected of 80 unerupted teeth. These were frozen in demineralized water immediately after extraction. Since the teeth have not been in an oral environment, the enamel surface diffusion layers are presumed to have equivalent mineralization-demineralization rates.

At conclusion of demineralization studies, selected specimens were immersed for 24 hours into a radioactive solution (S-35) and crystal violet. Specimens were embedded into plastic matrix and serial sections were cut for penetration studies by autoradiography and for macroscopic examination.

5.0570, CHARACTERIZATION OF SOIL & VEGETATION TO SERVE AS A BASIS FOR FUTURE EVALUATIONS OF RADIOACTIVE CONTAMINATION EFFECTS (ABBREV)

F. HAGHIRI, Ohio Agric. Res. & Dev. Center, *Wooster, Ohio* 44691 (AT(11-1))

Studies on the effect of soil and crop management practices on the removal of Sr 90 by runoff, leachate water and plant uptake under field conditions will be continued. Effect of paraquat

on Sr retention by organic matter and isotopic equilibration of Sr 90 sorganic matter and Sr ion will be studied. Effect of burning of vegetation containing Sr on the chemical behavior of Sr ion will be investigated. The ashing is to simulate forest fire and burning of crop residues. The ratio of inorganic anions to organic anions Sr will be determined and the various anions associated with Sr will be identified. The availability of Sr from ashed and dried plant materials in the soil to plants will be determined by using Stanford-Dement technique. In addition the movement of the Sr, from both ashed and dried plant sources, in the soil profile will be studied.

5.0571, EFFECTS OF PRENATAL AND EARLY POST-NATAL IRRADIATION

W. FRIEDBERG, U.S. Dept. of Transportation, Civil Aeromedical Institute, *Oklahoma City, Oklahoma*

Radiation sensitivity appears to be greatest during prenatal development and in the young. The proposed research will provide information useful in assessing the risk to the embryo, fetus and child of injury from solar flare radiation.

Relative effects of fission neutrons (high LET) and 250 KV X-rays (low LET) will be compared. The neutron source will be the Oak Ridge National Laboratory Health Physics Reactor (DOSAR). X-irradiation will be carried out in Oak Bidge and the Civil Aeromedical Institute. Initially, we plan to expose pregnant mice to single acute radiation doses of neutrons or X-rays in the range 1-100 rads on specific days after conception. Effects of fractionated irradiation will be investigated in later studies. Anomalies in the embryo and fetus, litter size and growth and development after birth will be studied. Tissue samples will be collected at selected times before and after birth for histological evaluation.

Mouse embryos at the one-cell stage of development were exposed to fission neutrons. This was accomplished by irradiating pregnant mice at about 0.5 day after mating. A few days before the end of the gestation period the embryos were examined and compared with nonirradiated controls. Results obtained to date indicate that as the neutron absorbed dose was increased from 2 to 5 to 10 to 20 rads, prenatal survival decreased. In this range, survival appears to be an exponential function of radiation dose with a D37 of 19 rads and an extrapolation number of 1.05. D37 is the radiation dose that will reduce a cell population to 37 percent on the exponential portion of a survival curve. Implantation of the mouse embryo occurs about 4.5 days after fertilization of the ovum; a resorption mole is the remains of an embryo that died within a few days after implantation. From the number of resorption moles and the total number of dead embryos, we conclude that more than 92 percent of the postimplantation deaths occurred before about day 10 in the 19 day gestation period. The data indicate that both preimplantation and postimplantation deaths increase with increase in radiation dose. Very few live embryos were seen with gross anomalies; two embryos with exencephalia (brain hernia) were found among the sham-irradiated controls.

5.0572, RESPONSE OF CELLS TO MAGNETIC FIELDS AND X-RAYS

G.D. ADAMS, U.S. Veterans Administration, Hospital, *Oklahoma City, Oklahoma* 73104

The general problem under investigation is the elucidation of effects which a constant magnetic field may have on biological systems, and particularly as a modifier of radiation injury.

In the first series of experiments, HeLa cells in culture constituted the biological system and the scoring was on the basis of individual cells to maintain proliferative capacity -- to grow to clones of at least 50 cells in 10 days. Generally, the magnetic field in the absence of radiation has small deleterious effect, yet was a protective agent in the presence of radiation. Precise quantitation has been difficult for technical reasons. Further experiments along this line are temporarily suspended a) to palliate the technical difficulties and b) to search in other biological systems for other remarkable duality in the behavior of magnetic field and radiation combinations. Preliminary results were reported to IVth International Congress of Radiation Research, Evian, France,. July 1970.

A new series of experiments has been started involving Swiss Webster mice as the biological system. Longevity and histopathologic changes are scored. All mice are irradiated and we study the effect of adding magnetic field during exposure, or of the chemical radiation modifier L-cystein, or of both together. Addition of magnetic field elicits a few earlier deaths but yet acts as a partial protective agent for a whole population. The L-cystein experiments are equivocal, in part due to the difficulty in obtaining the drug usable form. Preliminary results from these experiments were to be reported at the annual meeting of the Radiation Research Society, May 1971.

5.0573, ULTRAVIOLET INDUCED BIOCHEMICAL CHANGES IN SKIN

M.A. EVERETT, U.S. Veterans Administration, Hospital, *Oklahoma City, Oklahoma* 73104

Experimental procedures done at the VA encompassed some limited column chromatography and the actual C-14 counting.

It has been found that cis urocanic acid (UCA), formed from trans UCA in solution and in vivo by UV irradiation, is effectively excreted unchanged in the urine when administered by feeding or by intraperitoneal injection.

It has been shown that UV irradiaton of trans UCA in frozen solutions forms a dimeric product. The isomeric configuration of the dimer formed is dependent on the pH of the solution that is frozen for UV irradiation. When administered by intraperitoneal injection, the dimer formed from alkaline (pH 8.0) solutions is promptly and efficiently excreted in the urine by rats, whereas the dimer formed from solutions that are pH 5.9 is excreted largely by the liver via the bile duct into the feces. The efficiency of extraction by liver appears to be a genetic trait.

Current degradative studies have indicated that the dimers formed from UCA do contain a cyclobutane moiety as anicipated by analogy to the photochemistry of other gamma substituted acrylic acids.

The 'alkaline dimer' has all the trans configuration in the 1,3

$ series, while the 5.9 dimer has a cis-trans-cis configuration and belongs to the 1,2 series. As yet a procedure has not been found which will distinguish in vitro the 'alkaline dimer' from the '5.9' dimer, even though rats or guinea pigs excrete them by different routes.

5.0575, EFFECTS OF RADIATION ON PERMEABILITY AND ENZYMES OF SKIN

R.L. OLSON, Univ. of Oklahoma, School of Medicine, *Oklahoma City, Oklahoma* 73104 (AT(40-1))

We are investigating the penetration and distribution of various exogenous substances in normal and irradiated human skin. Relationships of these substances to lysosomes have been evaluated by electron microscopic histochemical techniques employing acid phosphatase and aryl sulfatase reactions. Lysosomes are being studied in acute and chronic skin injury in subjects of varied complexion and races. The effect of abnormal keratinization, found in chronic ultraviolet damaged skin, upon epidermal enzymes and permeability will be studied.

Results: We have described the intercellular circulation of macromolecules, epidermal phagocytosis of macromolecules, the

presence within epidermal lysosomes of acid phosphatase, the relationship of lysosomal enzymes to keratinization, the dispersal of lysosomal contents following ultraviolet injury, dyskeratosis in chronic ultraviolet damaged skin and other aspects of epidermal change following ultraviolet injury.

5.0576, RADIATION CHEMISTRY, PHOTOCHEMISTRY AND EXCITED STATES OF A) OXYANIONS, B) D.N.A
M. DANIELS, Oregon State University, Graduate School, *Corvallis, Oregon* 97331 (AT(45-1))

Objective: (1) To study the free radical reactions and transient species in the radiolysis and photolysis of oxyanions, to determine the mechanism of the 'direct effect' in aqueous solution, to investigate the role of excitation processes and energy transfer in the 'direct effect,' and the mechanism of U.V. photolysis. (2) To investigate the mechanisms of gamma radiolysis and U.V. photolysis of D.N.A. and related compounds.

Background: The aqueous anion systems are sufficiently simple to allow the possibility of complete accounting, and also exhibit strong 'direct effects.' The correlation of dilute solutions radiolytic studies with U.V. photolytic work may allow the detailed elucidation of the mechanism of the 'direct effect.'

The investigation of the radiolysis and photolysis of D.N.A. is fundamental to understanding the radiobiological effects involving D.N.A. It is proposed to examine the nature and role of various excited states and transient species by a) emission and b) flash photolysis studies.

Procedure: The radiolysis and photolysis of N03 ion will be investigated by standard procedures;O18 techniques will be developed.

Short-lived emission of pyridine components of D.N.A. will be quantitatively investigated and correlated with absorption spectra studies. Fluorescence behavior will be correlated with photochemical behavior and flash photolysis results.

SUPPORTED BY U.S. Atomic Energy Commission

5.0577, NEURAL DETECTION OF IONIZING RADIATIONS
D.J. KIMELDORF, Oregon State University, School of Science, *Corvallis, Oregon* 97331

There is reasonable evidence to indicate that the nervous system can respond to very small doses of ionizing radiations. No receptor is known for which ionizing radiation is the adequate stimulus, but radiation may be an effective stimulus for several receptor systems. Evidence for this point of view, however, is limited. Most of this work has been done in animal species that possess highly differentiated and complexly organized nervous systems. The present study is intended to provide a better basis for interpretation of ionizing radiation as a physiologic stimulus through a phylogenic study of prompt behavioral and neural reactions to small doses, their relative sensitivity, and the probable mechanisms through which these reactions occur. The study of mechanisms for biodetection in simpler systems can provide information that is instructive regarding the extent to which the efficiency of detection is dependent on the degree of neural organization and receptor specialization. Selected species will be exposed to ionizing radiation (X-rays, beta rays, gamma rays) under highly controlled conditions. Prompt reactions to exposure will be identified and analyzed from videotape recordings and assessed quantitatively by coupling with transducers and related sensor systems. Estimates of threshold intensities and dose will be derived from these data. Biodetection in responsive organisms will be investigated by several concurrent methods used to identify the receptor mechanisms. These involve exposure of specific sites, electrophysiological investigation of neural pathways, isolation of neuromotor systems, and comparisons with the action of other stimuli for the same response. The manner in which representative organisms of several phyla are informed about their own exposure can establish the systems that might, under certain conditions, serve usefully as biodetectors for the presence of ionizing radiations.

5.0578, UV MICROBEAM STUDIES OF MITOSIS
A.S. BAJER, Univ. of Oregon, Graduate School, *Eugene, Oregon* 97403 (AT(45-1))

The work combines studies in vitro with subsequent use of electron micrcroscope. The purpose of this final stage of research is to show that microtubules (MTs) are damaged within seconds after UV microbeam irradiation. It appeared that MTs disappear shortly after irradiation. However, a low depth of focus (about 2-3 microns) makes it difficult to pinpoint vertically the irradiated region due to variable optical conditions and UV absorption. Therefore, the following experiment will be done: bridges will be produced in metaphase on chromosome arms close to kinetechores. When such chromosomes begin to be stretched in anaphase, one of the kinetochores (and/or kinetochore fibers) will again be irradiated, the cell fixed, and the region located in electron microscope. Several experiments in vitro were already done. In these experiments, the kinetochore fiber is inactivated and non-disjunction follows. Efforts will be made to irradiate only a selected chromosome without affecting the others. Due to variation in chromosome arrangements in different cells, selection of appropriate cells for studies in vitro appear especially time consuming.

SUPPORTED BY U.S. Atomic Energy Commission

5.0579, RADIATION EFFECTS ON NUCLEIC ACIDS AND PROTECTION
G.J. KOLLMANN, Albert Einstein Medical Center, *Philadelphia, Pennsylvania* 19141

The proposed project involves continued study on he mechanism of protection of nucleic acids against the effects of ionizing radiation.

The 'in vitro' synthesis of RNA with irradiated and control templates will be further investigated. Radioactive precursors labelled with C-14 atom will be used to establish the overall syntheses. The results obtained will be compared to experiments carried out with P-32 labelled (Beta, Gamma) positions precursors. Both experiments will be conducted with control and irradiated templates. The ratios of P-32 to C-14 in the resulting polymers will indicate the effects of radiation on the initiation vs. the propagation steps. The experiments described above will then be carried out with protected and unprotected DNA templates, with bis(2-guanidoethyl) disulfide (GED) used as the protective agent.

The effects of radiation on DNA synthesis 'in vitro' will be investigated in the presence and the absence of protective agent. The results of these experiments will then be contrasted against the results obtained with the RNA syntheses. It is anticipated that this line of investigation will indicate at least part of the damage suffered by DNA, when irradiated, and whether effective protection against such damage can be achieved.

5.0580, RADIATION EFFECTS ON ERYTHROCYTE SODIUM AND POTASSIUM
B. SHAPIRO, Albert Einstein Medical Center, *Philadelphia, Pennsylvania* 19141

Earlier studies have shown that radiation induced alteration of erythrocyte permeability is accompanied by oxidation of membrane sulfhydryl groups. How this chemical change alters the K-Na barrier in the cell membrane is unknown. It can be partially reversed by reducing the disulfides formed. To further study this phenomenon, labelled agents which bind covalently to the erythrocyte membrane will be applied as markers before and after radiation. The membrane will then be dissolved and components separated. Membrane components affected by radiation will be studied for their identity and the nature of the radiation induced change. It is hoped that this information will help to elucidate the mechanism of radiation damage to cell membranes.

5.0581, IN VITRO EFFECTS OF IONIZING RADIATION ON GERMINAL EPITHELIUM OF HUMAN TESTIS & ON STEROID BIOSYNTHESIS OF LEYDIG CELLS
E. STEINBERGER, Albert Einstein Medical Center, *Philadelphia, Pennsylvania* 19141 (AT(30-1))

The objective of this study is to investigate the effect of ionizing radiation on human testicular tissue grown in vitro in the form of organ culture or cell culture. From animal studies, as well as from rather limited investigations in man, it is known that ionizing radiation at certain dose levels affects the spermatogonial germ cells primarily. The in vitro system developed in our laboratory we hope will permit us to define with greater precision the exact cell type affected directly by the radiation, the progression of damage and possible recovery. The effect on the germinal epithelium will be studied cytologically; the effect on Leydig cells and Sertoli cells will be evaluated from the viewpoint of their ability to synthesize steroid hormones, and also their ability to synthesize protein. The conventional radiochemical techniques for steroid studies and protein studies will be employed.

Results: The techniques necessary for this study have been set up. A number of cultures of human testes have been exposed to different doses of ionizing radiation. Cytologic and biochemical studies of these cultures are in progress.

5.0582, EFFECT OF IONIZING RADIATION ON THE DISTRIBUTION OF DEOXYRIBONUCLEASES AND PHOSPHATASES IN SUBCELLULAR FRACTIONS OF GUINEA PIG EPIDERMIS
J. TABACHNICK, Albert Einstein Medical Center, *Philadelphia, Pennsylvania* 19141 (AT(30-1))

After 3000 rep beta-irradiation (90Sr-90 Y) to guinea pig skin, assay of epidermal homogenates showed increases in lysosomal enzymes occurred after cell death (Radiation Res. 32, 293, 1967); thus, we have turned our attention to 'activation' of nonlysosomal hydrolases as a possible cause of radiation cell death. Our major objective is to elucidate the mechanism(s) for the early increase in extracellular epidermal DNase I after radiation injury (Radiation Res. 23, 594, 1964), or other skin trauma (J. Invest. Dermatol. 46, 555, 1966). Histologic changes indicate that the enzyme originates either in the epidermis or the blood via damaged peripheral capillaries, or both. Of five possible mechanisms considered, evidence to date suggests that either a release of preformed enzyme from epidermal cell organelles or an increase in the rate of DNase I synthesis are the two most likely possibilities. Experiments are planned to determine which of the two plays a major role. These findings should give some clue regarding possible 'activation' of this critical enzyme in other irradiated tissues where free DNase I inhibitor is a complicating factor.

5.0583, RADIOBIOLOGY RESEARCH PROGRAM
A.D. CONGER, Temple University, School of Medicine, *Philadelphia, Pennsylvania* 19122

1). Radiation damage to taste buds and acuity: A. Fine structure of radiation damage to taste buds: It is already known that radiadion causes loss of taste buds and cells and of taste acuity, probably by damage to the neurotrophic function of the taste nerves. Electron microscope study of the fine structure change in buds (loss of nerves, cells, and taste cell tips) after irradiation will be made. B. Effect of genetic neural defects on taste structure: Various neurological mutants, mostly myelin deficiencies, in mice will be examined to see if they cause also a deficiency in taste structure, and perhaps even enhanced radiosensitivity for taste bud loss.

2). Micro radiography of the microcirculation: A special contrast medium (30% lead oxide of micron-size particles in 10% gelatin, which is rapidly lethal) injected under controlled pressure in mice gives good filling of the capillary bed without leakage. High resolution microradiography reveals the vascular bed. This method will be used to study radiation damage to the circulatory bed in various body areas.

5.0584, STUDIES ON UV RADIATION CARCINOGENESIS IN MICE
P.D. FORBES, Temple University, School of Medicine, *Philadelphia, Pennsylvania* 19122

The work to be supported during this project period has as its aim the further clarifaication of several conditions and events leading to radiocarcinogenesis. Ultraviolet radiation is causally involved with the origin of some experimental and human skin neoplasia, but many basic questions about the mechanism remain to be answered. A number of problems are open to experimentation, and this project is designed to investigate the following: 1. What are the dose and dose- rate parameters for experimental carcinogenesis? What is the significance of erythema and inflammation in pre-malignant changes? 2. Regarding action spectra: How effective are different wave lengths? What are the physical limitations of penetration, absorption? What are the anatomic and physiologic contributions of epidermis and dermis in carcinogenesis? 3. How effective are pigmentation and other inherited factors in influencing the course of U.V. -carcinogenesis? 4. Can U.V. radiation act as one of the agents in 2-phase carcinogenesis (initiator, promoter, or both?)

In addition, efforts will continue in relating radiation effects on skin carcinogenesis and such cell proliferation models as hair growth and epidermal turnover time.

5.0585, THE BIOLOGICAL EFFECTS OF ENVIRONMENTAL RADIATION
F. URBACH, Temple University, School of Medicine, *Philadelphia, Pennsylvania* 19122

The program on 'Biologic Effects of Environmental Radiation' consists of a supporting Core Project and several projects in Innstrumentation (design of light sources and measurement devices, U. V. Photography, action spectra); Photochemistry (of bilirubin and chemical carcinogens); cutaneous biology amd Animal Models); (Radiation and Genetics of Animal Models); environmental Photobiology (therapeutic uses of light, study of phototoxic and photo allergic agents); and Ultra Violet Light and Skin Cancer (effect of UVL on benign and malignant tumors, Genetics and Epidemiology of skin cancer in man).

These projects are coordinated and support each other with man power and specialized equipment.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0586, PROBLEMS IN RADIATION EMBRYOLOGY
R.L. BRENT, Thomas Jefferson University, School of Medicine, *Philadelphia, Pennsylvania* 19107 (AT(30-1)-2071)

The purpose of this research project is to determine whether the mammalian embryo is more sensitive to the tumorogenic and life shortening effects of X-irradiation than is the same organism when irradiated after parturition (mouse). Secondly, the importance of dose rate will be evaluated with regard to determining the rate of recovery of irradiated embryos during the postnatal period. Thirdly, the extent and persistence of radiation induced biochemical and physiological alterations will be evaluated in the adult animal following their production at specific times during gestation in the rat fetus. Fourthly, the relative importance of oviduct irradiation and zygote irradiation will be investigated. Fifthly, studies concerned with variations and discrpancies in the response of the mouse and rat embryo will be continued. Lastly, attempts will be initiated to irradiate the yolk sac without irradiating the embryo or chorioplacenta.

5.0587, MECHANISM OF CREATINURIA IN IRRADIATED RATS

T.R. KOSZALKA, Thomas Jefferson University, School of Medicine, *Philadelphia, Pennsylvania* 19107

Our broad research objectives are (1) to elucidate the mechanisms underlying the creatinuria observed experimentally in myopathic states resulting from radiation exposure, and (2) to determine the role played by hormones and creatine storage in body compartments in influencing creatinuria.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0588, ADAPTIVE SPECIALIZATIONS IN LEARNING AND MEMORY

P. ROZIN, Univ. of Pennsylvania, School of Arts, *Philadelphia, Pennsylvania* 19104

It is the thesis of this project that there are genetically programmed specializations in learning and memory, relevant to the particular type of behavior or functional system involved and the species under consideration. In this system, research on specific hungers, poisoning, and radiation-induced aversions suggests two major specializations: (1) mechanism allowing a taste CS to be associated with an internal (interoceptive) US with long CS-US intervals (of the order of at least one-half hour); (2) a tendency for gustatory and olfactory cues to be associated with interoceptive USs, as opposed to visual auditory cues.

This research will involve (1) a confirmation of the existence of these mechanisms; (2) an attempt to define how they operate (in either 'physiological' or 'behavioral' terms); (3) a study of the phylogenetic generality of the mechanisms and how they vary in different species in accordance with differences in feeding requirements, food availability and food habits of each species; (4) examination of the existence and role of these specialized mechanisms in human feeding; (5) an extension of the general notion of specialized or 'pre programmed' learning to areas other than feeding, notably the areas of human memory and cognition; and (6) a consideration of alternative solutions to the problem of identification of beneficial or harmful foods, in terms of social communication or inheritance of adaptive food preferences.

5.0589, CORRELATION OF LIFETIME HEALTH & MORTALITY EXPERIENCE OF AEC & CONTRACTOR EMPLOYEES WITH OCCUPATIONAL RADIATION EXPOSURE (ABBREV)

T.F. MANCUSO, Univ. of Pittsburgh, School of Public Health, *Pittsburgh, Pennsylvania* 15213 (AT(30-1)-3394)

A 1-year (1965) feasibility study determined availability of amounts and kinds of data for a radioepidemiologic study of atomic energy workers in selected AEC facilities. A 5-year pilot study was then initiated to begin a limited study of these and develop methods for extension to all AEC contractor facilities. This would be statistically necessary to study the presence/absence of effects on human populations of low-level occupational radiation exposures received by atomic energy workers. Previous reports discussed in detail project objectives, design and data abstracting procedures. All personnel and radiation data at Hanford are now on magnetic tape. Radiation exposure data for the three Oak Ridge facilities is on tape and the personnel data will be completed during the next year. Other environmental and job identification data have also been taped during the past year. Deaths are being identified through the Social Security Administration and death certificates will be requested from the states to determine causes of mortality. Ultimately, various statistical tests will be carried out to detect the presence or absence of any correlation between occupational exposure to radiation and/or other agents and differential and total mortality rates.

5.0590, RADIATION CHEMISTRY AND RADIOBIOLOGY OF MEDIUM EFFECTS

J. SCHUBERT, Univ. of Pittsburgh, School of Public Health, *Pittsburgh, Pennsylvania* 15213 (AT(30-1)-3641)

The objectives of the proposed research are to investigate the chemical changes produced in irradiated media and selected foods, especially those associated with carbohydrate fractions, and to correlate these chemical changes with their concomitant biological manifestations. The latter include growth rate of 'S. typhimurium' and cytogenetic changes in mammalian systems. We have identified glyceraldehyde and erythrose, which in the presence of O2 and/or H2O2, are the biological damaging agents produced upon radiolysis of sugars. Only aldehydes capable of forming peroxylactones, especially upon heating in aqueous solution, produce chemical and biological effects manifested by irradiated sugars. We propose to investigate: (1) The total carbonyl yield in irradiated carbohydrate; (2) Identification and quantification of the individual carbonyls; (3) The cytogenetic, antibacterial, mutagenic, and chemical effects of the peroxide adducts of carbonyls, especially with and without autoclaving and in the presence and absence of H2O2; (4) Quantitative comparisons of the action of irradiated sugar solutions with the amounts and kinds of carbonyls formed; (5) The chemical changes induced in DNA and its components by irradiation as related to the chemical properties of the carbonyl- peroxides and the peroxide adducts.

SUPPORTED BY U.S. Atomic Energy Commission

5.0591, RADIATION CHEMICAL STUDIES ON HEMOCYANINS

J. SCHUBERT, Univ. of Pittsburgh, School of Public Health, *Pittsburgh, Pennsylvania* 15213

Hemocyanins are non-heme oxygen-carrying proteins present in the hemolymph of terrestrial and marine invertebrates. In addition to their oxygen-carrying properties, hemocyanins also exhibit catalytic and peroxidatic activities. The objectives of the proposed research are to extend our previous investigations on the mechanisms by which ionizing radiation perturbs or destroys the three properties of hemocyanins. These various activities of hemocyanins are linked to the protein-bound copper, but the specific amino acids to which the copper is attached are unknown. Methods we have employed and will utilize include: (1) the use of OH and e super minus aq scavengers (2) the circular dichroism spectral change: (3) differential manometer and stopped flow methods for measuring rates of the catalytic reaction; (4) NMR and ESR for characterizing the active sites; and, (5) absorption spectra. We have shown that the radiation-induced inactivation and reactivation of the oxygen carrying activities of hemocyanins involve redox reactions of the protein-bound copper with radiolytic products of water. We have measured by competition kinetics the rate of reactions of the OH or e super minus aq interacting with copper moiety. Our proposed investigations on hemocyanin include: (1) the mechanisms responsible for the effects of ionizing radiation; (2) radiolytic reconstitution; (3) radiation-induced changes on the biological and chemical properties; (4) the nature of the active sites; and, (5) reaction kinetics of the OH radical and hydrated electron e super minus aq. The proposed investigations, overall, are intended to clarify many factors, known to be important in both the fundamental and practical aspects of radiobiology and oxygenation reactions. These include the oxygen effect; electron transport processes; protective and sensitizing mechanisms and effects of radiation on the secondary and tertiary structure of oxygen-carrying proteins.

5.0592, RADIOECOLOGY OF SMALL VERTEBRATE SPECIES UNDER NATURAL ENVIRONMENTS

C.A. TRYON, Univ. of Pittsburgh, School of Arts, *Pittsburgh, Pennsylvania* 15213 (AT(30-1)-2579)

The objective of the project is to determine the individual and population characteristics of suitable vertebrate species under natural environments of different stress and to utilize these

characteristics to gauge the effects of sub-lethal exposure to gamma rays.

Basic procedure is to livetrap and mark all the individuals composing given small mammal populations of known extent. By repeated recapture of these individuals throughout their life span, various structural and functional characteristics of both individuals and populations under the varying stresses of natural environments can be attempted. Two species, the pocket gopher (Thomomys talpoides) and the eastern chipmunk (Tamias striatus) have proven to be suitable for this procedure. Work will continue with both these species by exposing new members of marked populations to gamma rays. Investigation will also continue with the ecological energetics of both species.

Results: The large amount of data on free-ranging animals generated by this project and a similar one conducted by Dr. D.S. Snyder, University of Mass., have been entered and compiled for the UMASS remote access system. Data consist of population characteristics, individual life tables, morphometry, metabolic rates and blood characteristics. Gamma exposure has apparently changed the age composition, individual life expectancy and population turnover under natural conditions.

5.0593, CYTOGENETICS OF POST-IRRADIATION AND VIRAL LEUKEMIA

N. WALD, Univ. of Pittsburgh, School of Public Health, *Pittsburgh, Pennsylvania* 15213

The objective of this research project is to provide information leading to a better understanding of the interrelationship between radiation, cytogenetic abnormalities, and virus in leukemogenesis. The study subject to be utilized for this purpose is the RF/UN mouse which develops a high incidence of granulocytic leukemia on radiation exposure. A virus-like agent has been demonstrated in such leukemic animals and the disease has been transmitted by cell-free passage of materials from irradiated primary animals to normal recipients. Consistent abnormal chromosome markers and modal shifts have been observed in both irradiated leukemic animals and in animals developing leukemia after injection of material from the irradiated primaries. In addition, sequential changes of both markers and modal numbers over many transfer generations have been found. These appear to relate to alterations in the clinico-pathologic nature of the leukemia. It is therefore proposed to continue to seek evidence in this mouse leukemia system for: a) a relationship between consistent bone marrow chromosome aberrations and post-irradiation primary and passaged leukemia; b) a relationship between variations in the chromosome aberrations on passage, and the clinico-morphologic characteristics of the disease; c) a cause-effect relationship between the consistent chromosomal aberrations and the occurrence of leukemia; and d) a predictive relationship between the early peripheral blood count and chromosome changes induced by radiation, and the subsequent development of leukemia.

5.0594, GAMMA RAY EFFECTS ON DICTYOSTELIUM DISCOIDEUM

R.A. DEERING, Penn. State University, Graduate School, *University Park, Pennsylvania* 16802

The cellular slime mold, Dictyostelium discoideum, is an excellent model system for studying differentiation and development. Here we are investigating the effects of gamma irradiation on the macromolecular metabolism and development of this organism. In initial studies, it was found that the vegetative amoeboid cells are extremely resistant to gamma rays. In one phase of the work, the molecular processes responsible for this resistance are being sought. Toward this end, several mutants have been isolated which are more sensitive to gamma rays than the NC-4 wild type parent strain. The most sensitive has a D10 of 4 krad as compared to 300 krad for the wt. Experiments are now under way to determine the fate of DNA single strand breaks produced by the gamma rays, in thre resistant and sensitive strains. Since all results so far indicate that the resistant strains possess very effective 'repair' mechanisms, we will also try to isolate and identify possible enzymes responsible for this repair. In another phase of this work, gamma ray effects on development are being investigated in terms of numbers and viability of spores produced after irradiation at various stages. This will be done for resistant and sensitive strains. Eventually, it is our aim to use radiation as a tool to tell us something about the molecular events underlying differentiation in D. discoideum.

5.0595, BASIC ASPECTS OF THE ACTION OF RADIATION ON MICROORGANISMS

E.C. POLLARD, Penn. State University, School of Science, *University Park, Pennsylvania* 16802 (AT(30-1)-2804)

The long-range aim of this project is to characterize the site(s) and the nature of radiation action on microorganisms. The findings of the past will be followed up and related to yet other organisms and systems. For example, evidence for a marked repair-type process in E. coli C is being studied. Sucrose gradient studies on post irradiation RNA will be pursued in relation to the biphasic dose response. Also we propose to separate cells by sucrose gradient sedimentation to see if we can discover populations of cells corresponding to the all-or-nothing pattern. We can now study the reassociation of residual DNA and thereby shed light on the question of whether a defective prophage protects from degradation or simply switches the DNA to phage DNA. With the poly U polyphenyl alanine system we intend to test the effect of radiation on ribosomes and of irradiated medium on the synthetic process. By studying the sensitivity of E. coli B sub s-1 for phage T4 growth we hope to find a convenient way to observe the effect of radiation on ribosomes. We intend to carefully test the statistical cross section relation super S colonies equals super S DNA degradation plus super S DNA synthesis plus suber S trans plus super S p phage plus super S unbal in the hope of arriving at a rationale for radiation action.

Results: Messenger RNA half-life is increased after irradiation. There is a polar effect in the lac operon after irradiation, probably due to ribosome damage. There are two phases to the synthesis of post- irradiation RNA - a low dose and a high dose reduction. Rifampicin, which binds to the RNA polymerase, potentiates DNA degradation and sometimes increases colony-survival sensitivity. We have found that irradiated B. subtilis spores do not undergo DNA degradation, but if irradiated while germinating degradation appears.

5.0598, STUDIES ON RADIATION-INDUCED HERITABLE LESIONS IN SOMATIC CELLS

M. KOPEC, Inst. of Nuclear Research, *Warsaw, Poland*

This research project is designed to carry out investigations into the qualitative and quantitative characteristics of radiation induced heritable lesions in mammalian cells. Preliminary experiments indicate that high proportions of cell populations surviving irradiation with doses of 100-300 rads bear sublethal but heritable lesions, which manifest themselves in reduced proliferative

capacities of the damaged cells. For a certain dose range the surviving populations seem to contain constant proportions of normally growing cells and cells growing at rates below the normal one.

Studies on the growth kinetics of murine leukemic lymphoblast (L 5178 Y) cell populations irradiated with doses of X-rays ranging from 5 to 1000 rads are planned for establishment of quantitative relationships between dose of ionizing radiation absorbed by cell population and occurrence of heritable lesions. Particular attention will be given to estimation of the lowest doses inducing heritable lesions which affect proliferative activities of the cell populations, and of the highest doses after which individual cells can still proliferate normally. Verification of the conclusion, drawn from the available data, that the composition of the surviving cell population is dose independent in a certain dose range, may be of great importance for understanding of the mechanisms involved in the induction of the heritable lesions. Comparison between induction of heritable lesions in diploid, aneuploid and tetraploid sublines of the cell population, isolation of pure heritably damaged cell lines, comparison of the duration of individual cell cycle phases in normally growing and heritably damaged cells, and biochemical comparison of these two cell populations are planned for exploring the nature of the radiation induced inheritable lesions in somatic cell populations. Good understanding of qualitative and quantitative relations governing occurrence and repair of these lesions is indispensable for proper interpretation of phenomena occurring in higher organisms after irradiation, in particular the late effects.

5.0599, FOLLOW-UP STUDY OF THOROTRAST PATIENTS

J. DASILVAHORTA, Hospital De Santa Maria, *Lisbon, Portugal*

In our previous research (Grant no. RH00039) we have found that about 2400 persons have received 'Thorotrast', mainly by systemic route, from 1930 to about 1955, and we have been trying to trace them and learn the possible undesirable effects of that contrast drug. We have been able so far to trace about 50% of them and to follow them up since reception of the drug until the present moment or until death. The main results of our investigation have been regularly reported in some detail to the grant authorities and published in 'The Lancet', July 31, 1965, pp. 201-205 and in the 'The Annals of New York Academy of Sciences', 145: 676, 1967; 145; 700, 1967; 145: 776, 1967; 145: 811, 1967 and 145: 830, 1967. At the moment we have still 351 Thorotrast patients alive whom we are following up with increasing frequency and detail, since they are nearing extinction. Since 1966 we have been following also a group of control cases (patients injected with a non-radioactive contrast drug) and have been able so far to trace about 660 of such cases. We consider the number of controls traced still very low and need to increase our efforts and methods to trace more of them, in order to make valid comparison of results. A renewal of the present grant for a period of at least 2 years is badly needed for this end and also to study more thoroughly the Thorotrast cases and new aspects of these cases, such as their lung, bone and haematologic pathology. They represent a unique population which we hope to use to establish information about the dose-effect relationship between radiation to the bone and osteosarcoma, to the lung and lung cancer and to the haematopoietic system and leukemia and other malignant blood dyscrasias. In view of the renewed interest of the Thorotrast cases, because of the relevance of lung cancer in both these cases and the uranium miners and also on account of the expected increasing use of nuclear energy of which thorium would constitute an important source, it seems urgent that both pathological and epidemiological studies be continued while the patients are still alive.

5.0600, VIRUS PROJECT

J. CHIRIBOGA, U.S. Atomic Energy Commission, Div. of Med. Sci. & Radiobiol., *San Juan, Puerto Rico* 00935 (AT(40-1))

Radiation Activation of Latent Viruses in Wild Arthropods and Vertebrates.

A. Effect of gamma irradiation on the infection of mice and rats with coxsackie virus.

Adult white mice are normally resistant to coxsackie virus infection, but when these animals were exposed to whole body gamma radiation and immediately inoculated with coxsackie virus type A10 the blood and organs showed a consistently high concentration of virus, which varied directly proportional to the radiation dose. Similar experiments using adult wild rats (Rattus rattus), adult albino rats and adult hooded rats showed the same results as those obtained with the mice, except that the viremia lasted for at least 8 days in the irradiated rats.

B. Activation of coxsackie virus by radiation.

Active coxsackie virus was isolated from groups of animals (mice and rats) that were inoculated with the virus and later irradiated with gamma rays. No virus was isolated from the non-irradiated group. The active virus was either present in very low concentration, thus escaping detection, or it was in a 'latent' state and was activated by the irradiation.

C. Isolation of virus from immune animals after gamma radiation.

Adult mice could be immunized with coxsackie virus by inoculating intraperitoneally. The animals developed neutralizing antibodies. No active virus was isolated from these animals. When the animals were irradiated 60 days after the last inoculation, active virus was isolated from the spleen and pancreas. Several experiments were performed in order to determine if antibodies must be present in the animal in order to be able to recover active virus by radiation from previously immunized animals. The results could be summarized as follows: a. Active virus was isolated from irradiated immunized animals with antibody present in the serum. b. No virus was isolated from non- irradiated immunized animals with antibody present in the serum. c. No virus was isolated from irradiated immunized animals with no antibody present in the serum. d. No virus was isolated from immunized animals that showed no antibody present in the serum, whether or not they were irradiated.

5.0602, STUDIES ON THE EFFECT OF NEUTRON IRRADIATION ON SEEDS

C. CHENG, Natl. Tsing Hua University, *Hsinchu, Republic of China*

The methods for neutron dose measurement in a standard neutron irradiation facility for research reactor using barley seeds as the biological dosimeter are discussed, and the results are compared with those obtained by other reactor laboratories in order to obtain an accurate and reproducible set of data.

Dry seeds of rice varieties IR-20, IR 22, Taichung Native 1 and Tainan 5 will be subjected to 3 doses of neutron treatment and one dosage of 30 Kr X-ray irradiation as check.

The treated seeds as well as the untreated ones will be sown in greenhouse in February 1971, and the surviving seedlings transplanted by means of a single seedling planting.

Field notes will be taken on the performance of seedling growth, percentage of survived seedling, seed-setting, chlorophyll ueficiency and other biological effects, in addition to the cytological studies of chromosomal aberrations.

The N1 materials will be transplanted in the field in July 1971. Every treated lot of a single variety will be grown with at least 1000 plants.

Rice plants which differ from the parental varieties either in morphological characters or physiological performance will be harvested and seed samples of these plants sent to the quality-testing laboratory of the Taichung DAI S for determining protein content.

5.0603, EFFECTS OF RADIATION ON MIGRATORY ORIENTATION OF SALAMANDERS
C.R. SHOOP, Univ. of Rhode Island, Grsduate School, *Kingston, Rhode Island* 02881 (AT(30-1)4175)

The objective of this study is to determine the effects of artificially induced ionizing radiation on the orienting ability of the salamander, Ambystoma maculatum. In addition, knowledge will be advanced relative to the basic ecology of amphibians. This investigation will provide information of the individual and population attributes of reproductive potential, larval survival and net juvenile production, age and sex composition, population size, growth rates survival and longevity of adults, dispersal, and interchange between populations, and importance of larval salamanders to pond ecosystem.

Breeding ponds are fenced, and traps along the inner and outer faces of the fences catch animals as they are migrating to and from the ponds. Additional fences and traps at some distance from the ponds provide information on routes of travel. These procedures allow an annual census of the breeding populations, facilitate the correlation of directional movements of migrants to and from breeding ponds, and allow definition of juvenile production. Preserved samples from other ponds and laboratory studies of aging and reproductive behavior support the field studies.

Results: Migrating animals show a marked preference in their direction of departure from the breeding pond which is correlated with the direction from which they arrived. Data already collected suggest that many animals utilize the same route of travel in subsequent years. The animals apparently do not use celestial cues in orientation, and the sensory basis for the orienting ability is unknown. The orienting phenomenon will be used to determine radiation effects. Radiation tolerance studies have been initiated.

5.0604, RESPONSE OF PIGMENT CELLS TO X- AND UV-RADIATIONS
W.C. QUEVEDO, Brown University, Graduate School, *Providence, Rhode Island* 02912

The proposed project is directed at determining the extent to which the responses of mammalian pigment cells to UV- and X-radiations arise from direct modification of the irradiated cell or are dependent on events initiated within the particular cellular community of which it is a part. The problem of pigment cell 'niche' and radiosensitivity is examined and is subjected to experimental analysis. The significance of melanin pigment as a radioprotective agent is evaluated in the case of epidermal melanocytes. Particular emphasis is placed on determining the consequences of the proposal that the epidermal melanin unit, consisting of a melanocyte together with its constellation of associated epidermal cells (keratinocytes), is the fundamental integrated unit of pigmentary function in the epidermis of vertebrates. The functional and morphological properties of the epidermal melanin unit are examined in the skin of vertebrates representative of each of the major classes. Particular attention is given to the roles that genes and hormones play in modifying the responses of mammalian melanocytes to ionizing and ultraviolet radiations. The cellular basis for radiation-induced changes in melanocyte populations and the nature of cellular interactions during pigmentation of skin and hair are also examined.

5.0606, EFFECT OF WHOLE BODY X- AND GAMMA-IRRADIATION ON THE BIOSYNTHESIS OF CERTAIN SERUM PROTEINS
O.W. NEUHAUS, Univ. of South Dakota, School of Medicine, *Vermillion, South Dakota* 57069 (AT(11-1))

Changes in liver cell permeability occur when the animal organism is subjected to stress or exposed to X- and gamma-irradiation. We will study factors controlling the uptake of amino acids under these conditions. For most studies the unmetabolizable amino acid, alpha- aminoisobutyric acid will be used. Studies will include effects of adrenalectomy, hypophysectomy as well as therapy with hormones and analogues. We hope to establish a relationship with the cyclic AMP- adenyl cyclase system.

We will study effects of whole body irradiation on transcriptional and translational processes in protein biosynthesis. Spayed female rats treated with testosterone to stimulate a selective synthesis of male-sex dependent 'urinary' protein, will be exposed to whole-body irradiation. 14 C-orotic acid incorporation into RNA, polysomal stability, and effects on the endoplasmic reticulum will be determined.

Low dosages of irradiation appear to stimulate the synthesis of acute-phase plasma proteins. The identity of responsive proteins will be determined as well as changes in RNA synthesis, nuclear polymerase activity, polysomal profiles, polysomal stability and ribonuclease activity.

Results: 1. Whole body X-irradiation and inanition suppressed amino acid incorporation in liver microsomes. 2. Liver microsomes of irradiated rats are not defective since phenylalanine incorporation with poly U is normal. 3. Lethal X-irradiation but not inanition inhibits biosynthesis of polysomal and nuclear RNA. 4. X- and gamma-irradiation causes an increase in hepatic uptake of AIB.

5.0607, EFFECTS OF ULTRAVIOLET RADIATION ON ALGAE - MECHANISMS OF INACTIVATION AND REPAIR
G.D. SMALL, Univ. of South Dakota, School of Medicine, *Vermillion, South Dakota* 57069 (AT(11-1)1793)

The objective of this project is to study the mechanisms for the repair of UV-light induced damage in the DNA of model eukaryotic cells, the single-celled green algae. The most extensive information concerning the damaging effects of UV-light to DNA and repair systems for this damage are available for bacteria and their viruses. We are interested in (a) whether the mechanisms of inactivation and repair are the same in eukaryotic cells such as algae compared to bacteria, and (b) whether organelles such as chloroplasts and mitochondria have DNA repair systems independent of those in the nucleus. Photoreactivating enzyme is found in both the nucleus and the chloroplasts of Euglena gracilis. A systematic study of these enzymes is underway. A method to detect photoproducts in UV-irradiated algae is being developed. Finally, enzymes involved in the excision-repair mechanism in Chlamydomonas are being studied.

Results: 1. Photoreactivating enzyme has been detected in purified Euglena chloroplasts. 2. Photoreactivating enzyme from extracts of Euglena cells has been purified over 200-fold. 3. Crude extracts of Chlamydomonas have been found to degrade UV-irradiated DNA much faster than nonirradiated DNA, indicating the presence of enzymes specific for UV-irradiated DNA.

5.0609, EXPERIMENTAL INVESTIGATIONS ON THE INTERPLAY BETWEEN NATURAL AND ARTIFICAL RADIATION PROTECTION

L. REVESZ, Karolinska Institutet, *Stockholm, Sweden*

The work will continue in the lines of the first year. One part will be directed to the further clarification of the effect of cysteamine on the natural repair of the cellular radiation damage, occurring in the intervals between the fractionated irradiation. The slope and the extrapolation number of the survival curves as well as the long term growth of the irradiated cells in tissue culture will be followed and the modification of these parameters by cysteamine will be studied. These results should show whether the cysteamine modifies the degree of radiation damage only or stimulates its repair as well.

The second part of experiments will concern the chemical exchange reactions between the internal, i.e. natural and the external radioprotectors. It is planned to use for this study both the cells internally labelled with radioactive cysteine and radioactive cysteamine in normal cells. The subsequent chemical and radiochromatographic analysis will bring data on the fate of the labelled cysteamine in cells, on the process of intracellular release of natural protectors (mainly glutathione) induced by cysteamine and eventually on the formation of so called mixed disulphides between proteins and protector.

5.0611, ANIMAL METABOLISM OF FISSION PRODUCTS AND RELATED NUCLIDES

M.C. BELL, Univ. of Tennessee, Agricultural Experiment Sta., *Knoxville, Tennessee* 37916 (TEN00063)

OBJECTIVE: Determine absorption, distribution and excretion of fission products in beef cattle, sheep, swine and animal products as affected by different factors; determine feasibility of predicting fission product metabolism from that of related nuclides.

APPROACH: Strontium will be substituted for a part of the dietary calcium to determine the effect on absorption, distribution and excretion of Sr-89, Ca-45 and stable Sr and Ca in beef cattle. In vivo and in vitro techniques will also be employed to study fission product metabolism by rumen microorganisms. The effect of monovalent cations on cesium retention will be determined. Basic information will be obtained on the deposition and lability of bone-seeking fission products by dosing newborn animals and following the deposition and erosion pattern at various intervals throughout the growing period. Auto-radiographic techniques combined with microscopic examinations will be used to study the dynamics of bone calcification and decalcification.

PROGRESS: Sheep fed insoluble Y-labeled fallout simulant at 2.5 mCi/kg to simulate 7% forage retention developed anorexia, diarrhea, and weight loss. Tissues most damaged were the rumen and abomasum where the Y sand collected. Feed intake of survivors usually returned to normal within 60 days. Beta irradiation of 57,000 rads to the dorsum of sheep, severely affected the skin and reduced body weight. Whole-body gamma irradiation of 240R at 1 R/min affected only the platelets and white blood cells. No mortality was observed from these three types of irradiation alone but when combined, 4 of 8 sheep died in 60 days. 4 of 4 steers given the 3 combined treatments died within 30 days. Plasma mineral changes were observed only on beta-irradiated sheep and cattle. Sheep fed Y sand and those beta irradiated to the skin showed increased Zn in vitro erythrocytic uptake and increased plasma Cu. Most changes in sheep fed Y sand were observed from 7 to 42 days and included depressed plasma Ca and Mg. Most of the changes in skin- irradiated sheep were seen after 60 days and included depressed plasma Fe. These plasma changes are probably associated with tissue repair.

SUPPORTED BY U.S. Dept. of Agriculture

5.0612, RADIOTOXICITY OF FISSION PRODUCT ELEMENTS

M.S. BELL, Univ. of Tennessee, Agricultural Experiment Sta., *Knoxville, Tennessee* 37916 (TEN-UT-AEC-060102)

OBJECTIVE: The toxicity of radionuclides to the physiology of the animal with special reference to the Fission Product Elements.

APPROACH: Animals are subjected to various exposures to radionuclides and their effect on the physiology is noted. Special attention is given to the use of the Fission Product elements but not exclusive attention.

PROGRESS: In order to determine the vulnerability of livestock to fallout radiation, Y-labeled sand was fed to sheep at the rate of 2.5 mCi/kg of body weight to simulate fallout retention of 7 percent on forage. Severe radiation damage to the rumen and abomasum was accompanied by anorexia, diarrhea, and weight loss. Beta irradiation of 57,000 rads to 12% of the body surface severely damaged the skin and increased weight loss by 15% with no reduction in feed intake. Gamma irradiation of 240 R at 1 R/m affected only WBC and platelets. In 60 days, 4 of 8 sheep given all three treatments died and one of 8 fed Y sand died. Four of 4 calves given the 3 treatments died in 30 days with no deaths in calves on single treatments alone. Beta irradiation increased in vitro Zn erythrocytic uptake and altered plasma Cu, Fe, Mg, and Ca, while gamma irradiation had no effect on these elements. Two dairy cows surviving from a group of 6 fed 44 mu Ci Sr/kg of body weight in 1966 have been sacrificed at the termination of this phase of this project. They appeared healthy and it is estimated that their skeletal retention was less than 1% of the original Sr. The other 4 died from radiation injury 93 to 132 days after treatment with a bone retention of 8%. Due to the resignation of Dr. Cragle, this phase of the project is being terminated.

5.0613, EFFECTIVENESS AND EFFICIENCY OF PHYSICAL AND CHEMICAL MUTAGENS

B.V. CONGER, Univ. of Tennessee, Agricultural Experiment Sta., *Knoxville, Tennessee* 37916 (TEN00287)

OBJECTIVE: Study influence of modifying factors on radiosensitivity and mutability of plant seeds to fast neutrons. Compare mutagenic effectiveness and efficiency of gamma rays, fast neutrons and chemical mutagens alone and in combination treatments.

APPROACH: Seeds of various species of higher plants will be treated under various conditions of seed water content, atmosphere, temperature, etc. with fast neutrons, gamma rays and chemical mutagens separately and in combination. Various biological end points such as reduction in seedling growth, chromosome aberrations, mutation induction, lethality, and sterility will be measured. Particular emphasis will be placed on determining which combinations of mutagens and treatment conditions contribute to the highest rate of mutation induction relative to other kinds of damage produced. The basic mode of action of the mutagens (particularly fast neutrons) will also be studied.

PROGRESS: The influence of modifying factors, on response of barley seeds to unmoderated fission neutrons was studied. The post- irradiation oxygen effect observed in very dry barley seeds (2.2% water content) has not been previously reported for neutron irradiation of a 'dry' biological system. This effect disappears as the seed water is increased to 9.9 percent. Experiments on the post-irradiation oxygen sensitivity following gamma-irradiation of dry seeds from five species of higher plants differing widely in radiosensitivity and nuclear volume have been initiated. Results suggest a wide difference in the oxygen- enhancement ratio among the species studied. Seeds high in oil content appear to be less sensitive to post-irradiation oxygen treatment than seeds high in starch. The study of the mutagenic effectiveness and efficiency of gamma rays, fission neutrons and 14.7 MeV neutrons in barley is nearly completed. Both the fission neutrons

and the 14.7 MeV monoenergetic neutrons are much more effective in producing chlorophyll- deficient mutations than are gamma rays. Another experiment with barley to determine mutagenic effectiveness, efficiency and specificity of gamma rays, fission neutrons, ethylmethane sulfonate and 5-bromouracil alone and in combination treatments and after different periods of presoaking is currently being conducted.

5.0614, RESPONSE OF HORTICULTURAL PLANTS TO ACUTE GAMMA RADIATION

E.T. GRAHAM, Univ. of Tennessee, Agricultural Experiment Sta., *Knoxville, Tennessee* 37916 (TEN00230)

Objective: Determine the growth response of several horticultural species (vegetatively propagated plants) to acute gamma radiation. Locate the site of radiation injury in the apical meristems of irradiated plants, and to characterize the kind of injury necessary to cause the formation of abnormal stems, leaves, and flowers. Perpetuate by asexual reproduction any mutant or sport that may be of value to the nursery or florist industry.

Approach: The growth response study will consist of exposing actively growing plants to various dose levels of acute gamma radiation. Whole plant exposures of increasing increments will be used to determine the dose level required to bring about abnormal growth patterns and lethality to irradiated plants. Mutation rates and types of mutations in the irradiated plants will be compared to those of non-irradiated plants. Microscopic examinations will be made of apical meristems at various time intervals after exposure of the plant to acute gamma radiation. Abnormal growth patterns of the leaves, stems, and flowers will be related to radiation induced injury of the apical meristem. Material showing satisfactory horticultural characteristics will be propagated and maintained.

Progress: Fast Neutron Irradiation produced more changes than gamma. A buck mutant, from green to red, found in Coleus. Dwarf mutation of C. humus established. Few apparent mutations of woody materials have appeared.

SUPPORTED BY U.S. Dept. of Agriculture

5.0615, CELL SPECIALIZATION IN SHOOT APICAL MERISTEMS AS RELATED TO RADIOSENSITIVITY AND HISTOGENESIS

E.T. GRAHAM, Univ. of Tennessee, Agricultural Experiment Sta., *Knoxville, Tennessee* 37916 (TEN00273)

OBJECTIVE: Compare volumes of nuclei in meristematic cells in relation to radiosensitivity. Contrast DNA and RNA contents of irradiated and control apices. Trace origins of histogenic layers by means of normal and mutant plastids in cell lineages derived from apical meristems, using ionizing radiation to alter periclinal chimeras and to induce plastid mutation.

APPROACH: Irradiate periclinal chimeras of Dianthus, Euphorbia, and Coleus and prepare apical sections for microscopic examination by means of freeze substitution. Calculate volumes of nuclei from ocular micrometer measurements and relate these data statistically to degree of visible damage in tunica-corpus cells. Label irradiated apices with H- thymidine and H-uridine, fix in glutaraldehyde, embed in plastic, and section on the ultramicrotome. Analyze by histoautoradiographic and histochemical localization of DNA and RNA, using enzymatically extracted controls. Trace plastid lineages in natural and radiation-altered green/ivory variegated chimeras by means of a standard procedure for electron microscopy.

PROGRESS: A specific cytoplasmic injury was found in the shoot apex of young maize seedlings after an acute exposure to gamma radiation. The injury appeared as dense cytoplasmic condensates in interphase cells of the apical meristem and generative leaf tissue. Cytoplasmic condensation reached a maximum at about 12 hour postexposure and then disappeared during the next 24 to 36 hours, possibly due to autolysis. Severe shrinkage of cells occurred concomitantly with cytoplasmic condensation. Nuclear pyknosis in the shoot promeristem was another important injury induced by gamma radiation. Pyknosis was concentrated primarily in the corpus region of the promeristem, but was observed infrequently in the tunica. Pyknotic nuclei were prominent 24 to 36 hours postexposure, but were not observed after 48 hours. Cytoplasmic condensates accumulated during the first few hours postexposure and were clearly present prior to nuclear pyknosis. Both normal and pyknotic nuclei were colored pink in the Feulgen stain for DNA and blue in the aniline blue black stain for protein.

5.0616, EVALUATION OF MEAT FROM ANIMALS EXPOSED TO LETHAL RADIATION LEVELS

S.A. GRIFFIN, Univ. of Tennessee, Agricultural Experiment Sta., *Knoxville, Tennessee* 37916 (TEN00052-S)

OBJECTIVE: Evaluate the biological, physical and chemical properties of meat and evaluate methods of processing meat from animals exposed to lethal radiation levels.

APPROACH: Swine and cattle will be exposed to external gamma irradiation at a level to produce an LD 80-30. Animals will be slaughtered when they show signs of radiation sickness. Samples of blood, lymph, muscle, fat and organs will be studied for bacterial invasion. Physical and chemical properties of meat will be studied. Methods of processing under normal and possible post attack situation (no refrigeration) will be studied.

PROGRESS: Trials have been conducted with pigs irradiated at a level of 700 R at 1 R per minute. Bacterial examination of the blood has not indicated any bacteremia buildup. There has been no indication of bacterial buildup in the muscle. Some bacteria have been found in the lymph nodes. Trials were conducted with rats to evaluate reports that indicated bacteremia in irradiated animals. Bacteremia was produced in the rats.

5.0617, A STUDY OF EFFECTS OF RADIATION ON HOST-PARASITE RELATIONSHIPS

A.W. JONES, Univ. of Tennessee, School Liberal Arts, *Knoxville, Tennessee* 37916 (AT-(40-1)-1749)

Different stages in the larval development of Hymenolepis microstoma will be compared with similar stages in H. nana, H. diminuta, and H. citelli as to sensitivity to ionizing radiations. Infected flour beetles will be irradiated on days 1-6 after being fed tapeworm eggs, and the cysticeroids will be sampled periodically to observe delay in development and any specific effects.

Aging in Hymenolepis spp. in immunized and non-immunized hosts; the possible effect of host immunity upon senescence of potentially immortal cestodes will be tested by using X rays to suppress host immunity, then measuring the life span extension, if any, of the parasites.

Work will be continued on effects of radiation on fecundity of cestodes. Actual fertility will be measured by counting eggs ingested by the intermediate host, and comparing this number to 1) eggs hatched, 2) oncospheres reaching the hemocoele and 3) actual cysticercoids developing. The above measurements will be made on irradiated and non-irradiated cestodes.

Results: During FY 1968-9 observations were made of 1) retardation of Tribolium development by single and mixed infection with tapeworms, 2) changes in fecundity of Tribolium parasitized with Hymenolepis microstoma, 3) effects of radiation on H. microstoma developing in beetles and 4) continuation of a tapeworm 'selfing' study into the 15th generation. Publication of two papers and preparation of several others was accomplished.

5.0618, METABOLIC PROBLEM IN SECONDARY DISEASE

A.L. KRETCHMAR, Univ. of Tennessee, Memorial Res. Center & Hosp., *Knoxville, Tennessee* 37920 (AT(40-1))

Project aims are 1) correlate biochemical changes found in secondary disease of radiation chimeras with incidence of mortality and 2) determine the metabolic system or systems damaged critically by the disease. Changes in aspartic acid and serine metabolism are of particular interest. Observations made in mice with secondary disease uncovered changes subsequently found in animals with other forms of graft-vs-host disease. The radiation

chimera may thus be a model system for study of autoimmune disease, the cachexia of advanced malignancy, and, as most recently suggested, the natural phenomenon of aging. Mice will be lethally X-radiated and then given bone marrow from mice of different genetic background. Variation of dose of bone marrow cells, age of donor, sex of donor, and time of injection is controlled by systematic factorial design based on experimental design theory. The result is controlled variation of mortality rate which permits the biochemical changes found to be correlated with incidence of mortality in a formal way by use of mathematical statistical theory. Specific enzymatic activities in tissues, levels of tetrahydrofolic acid derivatives in liver, and the respiration pattern after injection of C14 labeled amino acids will be studied. This ongoing study of irradiation chimeras started in FY 67. Results: The level of aspartic acid is increased while serine is decreased in liver of radiation chimeras. The nitrogen balance is abnormal and there is unusual deposition of nitrogen in skin. Changes in respiration pattern after injection of labeled serine suggest that 'one carbon metabolism' may be altered.

SUPPORTED BY U.S. Atomic Energy Commission

5.0619, EFFECTS OF RADIATION ON REPRODUCTIVE PHYSIOLOGY IN FARM ANIMALS
R.L. MURPHREE, Univ. of Tennessee, Agricultural Experiment Sta., *Knoxville, Tennessee* 37916 (TEN00066)

OBJECTIVE: Evaluate effects of acute and chronic irradiation on reproductive physiology and growth in farm animals on: semen characteristics in the male, potential fertility in the male, estrual cycle phenomena in the female, potential fertility in the female, the endocrine system, growth of young animals.

APPROACH: Male and female cattle and swine will be exposed to varying levels of gamma radiation (Co 60). Observations will be made on the following: sperm production and fertility of males, lifetime fertility of females, viability, growth and fertility of offspring of females irradiated at different stages of gestation, histological and cytological changes in the ovary and testis following irradiation, and endocrine functions--pituitary, testis and ovary.

PROGRESS: The frequency of lambs with deformed legs born by ewes irradiated (200R, CO) on the 23rd day of gestation at rates of 0.3, 0.7, 1 and 47R/min. was 20, 33, 24 and 44%. No lambs with deformed legs were born by ewes irradiated on the 17th-22nd day of gestation. No deformed pigs were born by sows irradiated on the 15th-19th days of gestation (300R at 47R/min) or 20th-21st day at 1R/min. Dose-rates of 10 and 47R/min. on 20th-21st days resulted in near 100% of deformed pigs. Exposure of pregnant rats (dose 100R) at rates of 1, 2, 3, 4, 5, 10 and 47R/min. on 11th day of gestation resulted in 18, 37, 55, 65, 64, 51 and 56% frequency of young with abnormal eyes. Testis weights of males irradiated at 17 day of gestation at rates of 0, 3, 10 and 25R were 1.7, .4, 1.3 and 1.3 gm., respectively.

SUPPORTED BY U.S. Dept. of Agriculture

5.0620, EFFECTS OF RADIATION ON LARGE ANIMALS - SOMATIC
R.L. MURPHREE, Univ. of Tennessee, Agricultural Experiment Sta., *Knoxville, Tennessee* 37916 (TEN-UT-AEC-060101)

OBJECTIVE: The somatic effects of ionizing radiation on large animals.

APPROACH: Large animals are exposed to ionizing radiation under various conditions. The interaction of dose and dose-rate on various physiological parameters are investigated.

PROGRESS: The frequency of lambs with deformed legs born by ewes irradiated (200 R, Co, on 23rd day of gestation at rates of 0.3, 0.7, 1 and 47 R/min was 20, 33, 24 and 44 percent. No lambs with deformed legs were born by ewes irradiated on the 17th-22nd day of gestation. No deformed pigs were born by sows irradiated 1) on 15th-19th days of gestation (300 R at 47 R/min) or 2) 20th-21st days at 1 R/min). Dose- rates of 10 and 47 R/min on 20th-21st days resulted in near 100 percent of deformed pigs. Exposure of pregnant rats (dose 100 R) at rates of 1, 2, 3, 4, 5, 10 and 47 R/min on 11th day of gestation resulted in 18, 37, 55, 65, 64, 51 and 56 percent frequency of young with abnormal eyes. Testis weights of males irradiated at 18 days of gestation at rates of 0, 10 and 25 R were 1.7, 1.3 and 1.3 gm, respectively.

SUPPORTED BY Tennessee State Government

5.0621, IRRADIATION OF MILK COWS
E.W. SWANSON, Univ. of Tennessee, Agricultural Experiment Sta., *Knoxville, Tennessee* 37916 (TEN00221)

OBJECTIVE: Determine the effects on dairy cows of high-level, sub- lethal doses of gamma irradiation given pre-partum and in lactation.

APPROACH: Cows will be paired on the basis of previous lactation, and one of each pair will be irradiated about two months prepartum. Irradiated cows will be compared with the non-irradiated controls for feed consumption, milk production, hematological effects and milk composition. The irradiated cows will also be re-irradiated at mid- lactation. In addition, several other cows will be irradiated for the first time in mid-lactation, and the effects on change of the lactation curve, or other effects determined.

PROGRESS: Eleven cows were given 3 doses of 200r each whole body irradiation in 1965-66. Four years after the initial treatments 5 of the cows are still in the milking herd. In their 3rd or 4th lactations after irradiation, they will average about 17,000 lbs. of milk in lactations averaging 340 days. A similar control group of cows in the same herd averaged only 14,446 lbs. in 286 days, due to a poor lactation of one of the controls. In the past year one of the irradiated cows died 2 wks after calving from gastritis, and 2 cows presently milking became non-breeders; so at the end of 4 years only 3 of the original 11 will be in normal production. A comparable depletion has occurred in the control group. There is no indication that the irradiation has adversely affected lactation ability or longevity. Lactation comparisons are continuing with identical twins comparing thyroid damaged and control twins. Feeding thyroxine to thyroid damaged cows, after lactation had started, increased their milk yield, but they did not attain normal yields. When thyroxine feeding was started before calving, nearly normal yields resulted. This result confirms the importance of thyroid activity for lactogenesis.

SUPPORTED BY U.S. Dept. of Agriculture

5.0622, BINDING OF RADIOACTIVITY TO RAT LIVER NUCLEIC ACIDS IN VIVO AFTER ADMINISTRATION OF AAF-9-C-14 OR N-HYDROXY-AAF-9-C-14
C.C. IRVING, U.S. Veterans Administration, Hospital, *Memphis, Tennessee* 38115

Previous reports that radioactivity was bound to rat liver in DNA in in vivo administration of 2-acetylaminofluorene-9-C-14 (AAF-9-C-14) were confirmed. In addition, administration of several other AAF derivitives, namely N-HO-AAF-9-C-14, N-acetoxy-AAF-9-C-14 and the glucuronide of N-HO-AAF-9-C-14, led to the binding of higher levels of radioactivity to rat liver rRNA and DNA. Maximum levels of bound radioactivity were found in rat liver RNA and DNA at 12-16 hr after a single injection of AAF-9-C-14. Bound radioactivity disappeared rapidly from liver RNA, with approximately 3 days being required for one-half of the bound radioactivity to disappear. By four weeks after a single injection of AAF-9-C-14, rat liver RNA no longer contained detectable radioactivity. On the other hand there was persistent binding of radioactivity to rat liver DNA followng a single injection of AAF-9-C- 14. Approximately 10% of the bound radioactivity found at 12-16 hr remained associated with the DNA at 4-8 weeks after injection of AAF-9- C-14. There appeared to be at least two different mechanisms involved in the binding of N-HO-AAF to rat liver rRNA and DNA in vivo, since approximately 75% of the fluorene residues bound to rRNA after injection of N-HO-AAF retained the N-acetyl group, while the N-acetyl group was retained in only 35% of the fluorene residue bound to DNA.

SUPPORTED BY U.S. Veterans Administration

5.0623, NEOPLASMS AFTER FISSION NEUTRON IRRADIATION
H.H. VOGEL, Univ. of Tennessee, School of Medicine, *Memphis, Tennessee* 38103

Single, whole-body exposure to fission neutrons, of 10 to 250 rads, were followed by the development of at least one mammary

neoplasm in 73- 87% of irradiated Sprague Dawley/ANL female rats. There was no evidence of a linear dose-effect relationship. Control, unirradiated rats showed 48% mammary tumor incidence during their lifetime, no neoplasms appeared within the first ten months. After a single, whole-body exposure to 5 rads of fission neutrons 63% of the rats developed mammary neoplasia to date. Histopathological analysis of 102 mammary neoplasims in 95 irradiated rats showed 70.6% cases of benign tumors, 10.8 % cases of sarcomas and 18.6% cases of carcinomas. Thus a ratio of benign to malignant neoplasm was 7:3. The fibroadenoma was the most common mammary neoplasm following neutron irradiation. Of 127 female rats irradiated with 5 to 35 rads of fission neutrons, 7 demonstrated palpable mammary neoplasms within 100 days of irradiation. It is apparent that the adenocarcinoma is the most common type of neoplasm directly after neutron exposure.

5.0624, DOSE-TIME FACTORS INFLUENCING CELLULAR RADIOSENSITIVITY

J.S. BEDFORD, Vanderbilt University, School of Medicine, *Nashville, Tennessee* 37203

Three factors which markedly influence the dose-survival response of cells exposed to sparsely ionizing radiations are (1) the dose rate or manner in which the dose is fractionated in time, (2) the amount of dissolved oxygen present at the time of irradiation, and (3) the 'age distribution' of cells in various phases of their reproductive life cycle.

While each of these factors has received considerable attention in radiobiology, very little information is available on their interrelationships. It is not known for example, what changes in the 'age distribution' of cells in their reproductive life cycle may accompany prolonged low dose rate irradiation, prolonged anoxia, or both.

It is proposed that some light may be shed on these interrelationships by applying techniques of mammalian cell culture in combination with autorradiographic life cycle analysis. From such experiments, information of general interest in radiobiology will be obtained, and some insight may be gained toward providing a rational approach to cell life-cycle modulated tumor treatment regimes in radiotherapy.

5.0625, RENAL PHARMACOLOGY AND TOXICOLOGY OF FALLOUT NUCLIDES

B.V. RAMASASTRY, Vanderbilt University, School of Medicine, *Nashville, Tennessee* 37203

The renal excretion of various fallout radionuclides as well as their deposition in critical organs is probably achieved in part through their similarities and difference from the ions of common biologic occurrence. Therefore, the specific objective of this project is to study the relationships between the position of the various radionuclides (Cs 137, Sr90, Ba140 - La 140, Ca 47 - Sc 47, Zr 95 -Nb95, Ru 103 - Rh 103) in the periodic table and their retentive, excretory and toxicologic indicies in mammals. The selection of the radionuclides is based upon (1) their occurrence in the atomic fallout, (2) their potential as hazards to human populations, and (3) their scope as environmental pollutants. During 1970-71, the following were investigated: (1) Localization of the sites for the secretion of Cs 137, Rb 86 an K 42 in the nephrons of the same dog kidney by stop-flow and clearance techniques. According to these studies, all three radionuclides were reabsorbed in the proximal tubule and secreted in the distal tubule. Super 42 K and super 86 Rb were secreted at the same distal site. However, the distal secretory site for super 137 Cs was more proximal to that of K 42 or Rb 86. A distal tubular reabsorptive site could be demonstrated for K42 and Rb 86. Active reabsorption of Cs 137 was not observed. (2) Metabolic dissociation of the parent-daughter radionuclides Zr 95 - Nb 95. After intraperitonial administration of Zr 95 - Nb 95 in the transient equilibrium, the parent was preferentially absorbed and excreted in the urine during the first day. For 3 4 days, large amounts of the administered daughter was excreted. Between 7-42 days part of the mobilized Zr 95 decayed to daughter, which was probably translocated from bone and excreted in urine. After the 42nd day, the whole body loss of radioactivity was due to the physical decay of super Zr 95 - Nb95.

The following are the specific goals set for 1971-72: (1) Renal sites for reabsorption and secretion of radiostrontium in relation to radiobarium and radiocalcium; (2) Metabolic dissociation of the parent- daughter radionuclides, Ca 47 - Sc 47, Sr 90 - y 90.

5.0626, A STUDY OF INFECTIONS IN IRRADIATED PATIENTS

G.C. KINGDON, Oak Ridge Associated Univs., *Oak Ridge, Tennessee* 37830 (AT-(40-1)-GEN-33)

It is well documented that humans and animals exposed to total-body irradiation are rendered more susceptible to infection. This increased susceptibility has been studied in some detail in experimental animals; however, little information is available on humans. The purpose of this study is to examine the underlying causes of altered resistance in irradiated human subjects. Our principal goals are to: (1) characterize the microflora of patients undergoing irradiation therapy in order to determine if microbial population shifts occur prior to infection; (2) identify the pathogen(s) in any infection, their portal of entry, and response to treatment; (3) assess the affects of irradiation on humoral and cellular defense mechanisms. The aerobic and anaerobic microflora of the respiratory tract, gastrointestinal tract, urine and skin are examined qualitatively, quantitatively, and biochemically at frequent intervals. Immunoglobulin levels (IgG, IgA, IgM), and complement (C'3) are measured at weekly intervals before and after irradiation. Bacterial agglutinins, bactericidins, and opsonins as well as the phagocytic index of blood or leukocyte enriched fractions are measured at frequent intervals before and after irradiation.

Results: The most consistent changes in the bacterial microflora after irradiation were in components of the anaerobic microflora. Alterations were also observed in the aerobic microflora, generally as an acquisition of microorganisms in the upper respiratory tract. More subtle changes were observed in the biochemistry and morphology of certain normal microflora components. Radiation appeared to have little effect on bacterial agglutinin and bactericidal titers. Decreased immunoglobulin levels, especially IgA and IgM were observed in some patients after irradiation.

5.0627, RADIOBIOLOGY AND NEOPLASIA - MORPHOLOGIC ASPECTS - HISTOPATHOLOGIC STUDIES

C.C. LUSHBAUGH, Oak Ridge Associated Univs., *Oak Ridge, Tennessee* 37830 (AT-(40-1)-GEN-33)

OBJECTIVES: 1) To define mechanisms of radiation injury to man by correlating histopathologic features with biochemical, immunologic, and microbiologic changes. 2) To determine distribution of administered radionuclides in normal and cancerous tissues after in vivo whole-body assays and scans. 3) To advance understanding of the marrow organ in hematologic diseases and therapy. 4) To define the graft-versus-host reactions in man, including their evolution and response to therapy. 5) To collect tissues for projects in cytogenetics, biochemistry, and electron microscopy.

Irradiated human and animal tissues are studied employing special stains and histochemical reactions to define responses. Causes of death are established, with particular attention to deleterious effects of radiation, including kinds of infections that accompany immunosuppression and granulocytopenia. Our facilities for whole-body irradiation permit comparison of animal and human tissues systematically exposed to a wide range of exposure rates. Another unusual resource is the capacity for whole-body counts, radioassays, and distribution studies of radionuclides. Radiation dosimetry is important for determining exposure from procedures of nuclear medicine. Radioassays also are important for developing agents that localize in tumors. Currently radionuclides of gallium are of interest, because their concentration in neoplasms promises to aid tumor detection and possibly will provide insights into the biology of cancer.

Results: In 1969 autopsies of 28 patients confirmed the presence of advanced neoplastic disease. With few exceptions the cause of death was infection and most of the infections would be considered opportunistic. Hemorrhage was often present but in this series was not the cause of death. GI ulcerations, pancytopenia, and immunologic supression were common, antineoplastic drugs complicated the analysis of effects of radiotherapy. Most patients had been given radiopharmaceuticals. Five had gallium-67 sufficient for detailed assays, helpful in the interpretation of scans showing localization of Ga-67 in tumors and tissues after IV administration.

5.0628, BIOCHEMISTRY OF LIPIDS AND MEMBRANES IN IRRADIATED AND NEOPLASTIC CELLS

F.L. SNYDER, Oak Ridge Associated Univs., *Oak Ridge, Tennessee* 37830 (AT-(40-1)-GEN-33)

The overall goal of this proposal is to determine the influence of irradiation, aging, and neoplasia on the molecular organization and function of membranes and on metabolic pathways for lipids in bone marrow, liver cells, cancer cells, and erythrocytes from mammals. The following projects are under investigation: (1) Effects of irradiation and aging on enzymic systems as related to the formation of fat cells in bone marrow tissue. (2) Effects of irradiation and aging on the structure and function of surface and intracellular biomembranes of liver cells and erythrocytes, (3) Lipid biochemistry of cancer cells, and (4) Radioprotective properties attributed to lipids and related compounds. The sources of tissues used in this research will be mice, rats, tissue culture cells (HeLa, Ehrlich ascites, and L-M fibroblasts) and humans.

Results: Forty publications on various aspects of the project have been published or accepted for publication. A complete listing is available from the Principal Investigator.

5.0630, RADIATION MUTAGENESIS IN MAMMALIAN CELLS IN VITRO

E.H. CHU, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

The availability of genetic markers and the demonstration by us of chemical mutagenesis in mammalian somatic cells in culture indicate the feasibility and desirability of studies on radiation mutagenesis in the same cell system. Our purposes are three-fold: (1) to find the dose- effect relationship in the induction of gene mutations in mammalian somatic cells in culture; (2) to identify the nature of the genetic alterations at the mutational sites following exposure to X-rays or ultraviolet light; and (3) to compare the spontaneous and induced mutation rates, (a) between different loci in various types of somatic cells 'in vitro', and (b) between the comparable loci in somatic cells in vitro and in the somatic and germinal cells in intact mammals including man.

We have initiated experiments in which Chinese hamster cells and normal human diploid cells 'in vitro' were exposed to various doses of X rays. The mutational change assayed was the forward mutation from 8- azaguanine sensitivity to resistance. Resistance arises from a loss or reduction in activity of hypoxanthine guanine phosphoribosyl transferase. In Lesch-Nyhan syndrome in man, the gene controlling the same enzyme activity is X-linked.

Results: The X-ray survival of the hamster cells fits approximately a multi-target relation. With the X ray dose range used (0 to 1200 r) the frequency of induced forward mutation as a function of survivors increases significantly with dose. Forward mutation to a presumably X-linked recessive is a single event at doses below 200 R. At higher doses, however, the mutant frequencies increase in proportion greater than the first power of the dose. Moreover, there is a saturation effect at doses higher than 800 R. By reversion test, we have evidence that in mammalian cells X rays induce both nucleic acid base changes and gross deletions.

5.0631, MAINTENANCE OF MEMBRANE INTEGRITY IN MAMMALIAN CELLS

J.S. COOK, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

Although in most cells DNA is the most sensitive target for many injurious chemicals or for radiation, there is evidence that surface membranes, which comprise a large and vital component of cellular structure, are also sensitive to noxious environmental factors. Surface-membrane damage is detectable physiologically by a decreased ability of cells to maintain their normal ionic relationships with their milieu; such lesions may be detected by changes in ionic composition of cells, changes in steady-state ionic fluxes, or concomitant changes in cell volume which may ultimately lead to lysis. In a number of cells, radiation-induced changes in such physiological parameters are reversible, a fact which implies that the membranes have been repaired. Techniques are now available for the isolation of surface membranes, and for the study of the turnover of chemical components of such membranes. We plan to correlate the physiological alterations observable in mouse ascites cells, which show rapid physiological repair, with turnover of membrane components. Non-nucleated mammalian erythrocytes, which carry out no protein synthesis, will be used as 'repair-deficient' controls.

Results: The ultraviolet action spectrum for erythrocyte lysis (known to be a membrane-damage phenomenon) has been determined. The distinct peak at 280 nm and trough near 255 nm implies absorption by aromatic residues in membrane proteins, and suggests further investigation of turnover of membrane proteins in the ascites cells. A correlation of the increased ionic fluxes after irradiation with cell- volume changes, and with the calculated safety factors representing the cells' ability to cope with these increased fluxes without lysis has led to an estimate of an LD50 for 'membrane death'. For human erythrocytes, this number is about 10 to the 3rd power ergs mm2 following irradiation at 280 nm.

5.0632, RADIOLOGICAL AND HEALTH PHYSICS HUMAN STUDIES

M.J. COOK, U.S. Atomic Energy Commission, Health Physics Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

Data needed for estimating absorbed dose from radionuclides entering the body are obtained by cooperating with staff of hospitals and universities where human data on stable element composition of tissues, diets, and anatomy are available. Specimens for analysis and data on weights and dimensions of organs are sought from grossly normal subjects coming to autopsy following sudden death. Currently, data are being gathered on blood content of lungs, weights of sections of the gastrointestinal tract, and composition of various types of bone- cortical, trabecular, cartilage. Cooperative studies are under way to estimate the position of the fetus in relation to other nearby organs (bladder, gastrointestinal tract) as preliminary to estimating dose to the developing fetus from photon emitters present in these organs.

Results: Data on trace element content of complete diets of a few adults have been obtained, the sampling extending over several years. Excreta of these same individuals have been analyzed as a basis for balance studies of individuals eating diets of their choice.

5.0633, THE EFFECT OF PREVIOUS PARITY ON THE INDUCTION OF OVARIAN TUMORS IN IRRADIATED MICE

G.E. COSGROVE, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

5. RADIATION

In a variety of radiation survival experiments previously performed on the RF mouse, it was repeatedly noted that exposure to sublethal whole-body radiation results in a marked increase in the incidence of ovarian tumors. The mice used in those experiments were always virgin females of differing ages. The effect of preradiation multiparity as an experimental modification of this system is unknown. The present experiment will compare ovarian tumor incidence (as well as life span and other disease incidence) in virgin females (either unirradiated or exposed to 150 R at approximately 6 months of age) or in females who have borne several litters of young, under the same treatment conditions. The procedures will be standard for those used in our survival experiments; maintenance in an open colony or a barrier colony, necropsy examination at time of death or terminal illness, and accumulation, storage, retrieval, and comparison of the life and disease data.

Results: The four groups of mice to be maintained in conventional colony conditions (virgin female-unirradiated or 150 R exposure, multiparous-unirradiated or 150 R exposure) have been set up and are some months post-treatment. Upon death, necropsies will be performed and data accumulation will progress. It is hoped to start the same types of groups in the barrier-maintained portion of the experiment.

5.0634, DISEASE OF WILD SMALL MAMMAL POPULATIONS ON RADIOECOLOGY STUDY AREAS

G.E. COSGROVE, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

The small mammals under study are those species involved in radioecology studies at ORNL, principally white-footed mice, cotton rats, rice rats, and shrews. These animals occupy various diverse habitats on the large AEC reservation area in Roane and Anderson counties in Tennessee. In order to tell if waste disposal, proximity to nuclear installations, etc. are having an effect on populations, it is necessary to know the usual activity patterns, diet, habits, reproductive performance, life span, diseases and other parameters in the populations involved. On the AEC area, control populations of the various species are available from uncontaminated sites for comparison with populations from sites with various degrees of contamination or disturbance. During the course of activities of the radioecology section, animals found dead or killed for test purposes are examined, and the necropsies are furnishing information on the disease parameters of the comparative populations. Where indicated, in-laboratory experiments are also performed on colony-maintained mammals of the same species. To a lesser degree, other species are monitored when available and other off-area sites are occasionally sampled for comparison.

Results: Information has beeen accumulated on well over 1000 mammals of several species and some case reports and extensive histologic reviews will be prepared. As new mammals become available, the information from their study will be integrated with that already available. Gross pathological and histological examinations are also being made on irradiated rodents living in field experiments and on wild species in laboratory experiments.

5.0635, CYTOLOGY AND TISSUE CULTURE IN GENETIC AND DEVELOPMENTAL STUDIES

R.B. CUMMING, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

We will continue to use a number of recently developed techniques to study radiation produced genetic damage in the mouse and to compare this with genetic damage produced by other agents.

One area of study which raises problems of practical concern, as well as giving insight into basic mechanism, is the induction of enzymes in the test animals by chronic feeding of antioxidants in the food prior to irradiation or administration of the test mutagen. The concern is over the facts, repeated below, that agents which give protection against genetic and somatic damage by chemical agents actually increase the risk of radiation damage.

A correlated type of study which we will continue to emphasize is the separation of specific germ cell stages from the mouse testis to assay for enzyme activities involved in repair of radiation-induced and other genetic damage.

A project has been completed on the effects of prefeeding of BHT (butylated hydroxytoluene) on subsequent damage by X-rays and radiomimetic compounds. Both somatic damage and the induction of dominant lethal mutations by X-rays are increased by BHT prefeeding. This is in the opposite direction from results obtained for a number of alkylating agents, where BHT prefeeding protects dramatically against both genetic and somatic damage. The marked contrast in effect between radiation and alkylating agents applies even to cyclophosphamide which gives somatic effects very similar to those produced by X-rays.

5.0636, COMPARISON OF DOSE FRACTIONATION AND PROTRACTION AND RBE FOR LATE SOMATIC EFFECTS IN MICE IRRADIATED WITH FAST NEUTRONS

E.B. DARDEN, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W)

The objective is to provide needed practical information as well as further insight into radiobiological mechanisms in regard to life shortening, tumor induction, opacification of the lens and other late somatic effects of ionizing radiation following whole body exposure of mice to acute, fractionated, and protracted whole body doses of fission spectrum neutrons and X-rays or gamma-rays. Mice are being or will be irradiated with single doses or fractionated doses at weekly intervals in the Health Physics Research Reactor with cumulative absorbed doses up to 200 rads. Protracted irradiation (1 rad/day) will be furnished by a small 252Cf source with a uranium housing to produce a simulated fission spectrum and substantially reduce the gamma/n ratio.

RESULTS: Preliminary results on induction of lens opacities (as observed with the slit lamp) with single doses of fast neutrons show that the RBE declines slowly or remains constant with increasing dose above about 100 rads. With decreasing dose, the reciprocal relation to dose becomes more pronounced and remains so at least to 1 or 2 rads. The completed results should allow RBE to be expressed as an analytical function of response parameters over a broad dose span down to threshold or near zero level for this particular mammalian tissue and aid in predicting dose-response behavior for other less radiosensitive effects.

5.0637, LETHAL EFFECTS OF NEUTRONS TO THE MOUSE ZYGOTE AND EARLY EMBRYO

E.B. DARDEN, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W)

The human implications of and lack of definitive information on effects of high-LET irradiation on mammals in the early prenatal period have prompted a study of radiation effects of fast neutrons on the zygote and early embryo in the mouse. Mice are mated overnight and those females showing vaginal plugs are irradiated a few hours later with single doses of fission neutrons or are sham irradiated in the Health Physics Research Reactor. Seventeen days later dissections are performed and the incidence of live embryos, dead embryos, and uterine resorption sites is tabulated. Neutron doses of 2, 5, 10, 15, and 20 rads are being utilized and compared to results obtained with X ray doses of 20, 40, 80 and 100 rads. Some mice have been allowed to come to term and the litters have been set aside to study the incidence of lens opacities and tumors and longevity.

RESULTS: An increase in prenatal deaths has been found at all neutron doses. It appears that survival is a decreasing exponential function of dose of neutrons. Increased prenatal death has also been seen at the higher X ray doses but the precise shape of the dose- response curve is not yet established. The relative biological effectiveness (RBE) of neutrons will apparently vary markedly with radiation dose level.

5.0638, MODIFICATION OF LATE SOMATIC EFFECTS OF RADIATION BY HYPOXIA

E.B. DARDEN, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

In an earlier study, irradiation of young adult RF mice with X rays (450-900 R) in a hypoxic gas mixture (5% oxygen in helium) as compared to air, gave a dose reduction factor of approximately 3 for life shortening. Also the dose-incidence relation normally found in this strain for radiation-induced leukemia (mostly thymic lymphoma) appeared to be displaced towards higher doses by hypoxic treatment but the data were not adequate to confirm this. We are now extending these observations to additional dose levels. Hypoxia had a definite but less pronounced effect on the induction or severity of radiation cataract. We have started experiments to see if this lack of protection for radiation injury to the lens cortex extends to lamellar or nuclear cataract, a subcapsular lesion induced before adulthood in high frequency by exposing newborn mice to moderate radiation levels.

Results: According to the initial findings in newborn mice. hypoxia reduces both the degree and severity of nuclear cataract produced by irradiation (150 R and 300 R) but the extent of the protection is yet to be determined.

SUPPORTED BY U.S. Atomic Energy Commission

5.0639, STRUCTURE OF THE SPORE-TYPE PHOTOPRODUCT

J.E. DONNELLAN, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

Ultraviolet irradiation of bacterial spores produced thymine photoproducts which were chromatographically different from cyclobutane- type pyrimidine dimers produced in vegetative cells or in free DNA. These spore photoproducts were also produced along with pyrimidine dimers in dry DNA and dry films of nucleotides and nucleosides of thymine. Dry films of thymine monophosphate will be irradiated in order to produce enough of the major spore product to elucidate its structure by conventional chemical means.

Results: Ultraviolet, infrared and NMR spectra are consistent with the spore photoproduct being 5'-thyminyl-5-(5,6,Dihydrothymine).

5.0640, RESPONSES OF ANIMALS TO IONIZING RADIATION

P.B. DUNAWAY, U.S. Atomic Energy Commission, Ecological Sciences Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

Major research objectives of these studies are to: (1) describe genetic constitutions of natural and laboratory populations and to determine effects on genetic structure by interacting influences of environmental stresses and ionizing radiation, (2) determine radiation effects on cells, tissue, life processes, and individuals of wild species, (3) measure effects of interactions between acute and/or chronic irradiation and environmental factors on populations, and (4) evolve models for prediction of radiation effects in animal components of ecosystems. These studies will provide data on the relative environmental hazard associated with the use of nuclear energy for peaceful purposes. Specific radiation-effected parameters being studied include mortality, reproduction, chromosomal aberrations, tissue damage, blood changes, metabolism, and age dependent effects. Organisms utilized for these studies include mammals, fish, amphibia, snails and insects. Comparative data on species differences, developmental stages, poikilothermy vs. homeothermy, competition, and environmental factors are providing essential input for predictive models of mixed population responses to radiation.

Results: 'Chironomus riparius' larvae reared in 250 and 500 micro curies H3/ml developed significant numbers of chromosomal aberrations but no aberrations were observed at the MPC level of 0.1 micro curies H3/ml. Blood changes are an important parameter for radiation effects and studies showed that Fe59 turnover reflects erythropoiesis, providing a useful non-destructive index for blood changes in free-ranging, irradiated mammals. The mean survival time of irradiated white-footed mice varies seasonally with a longest survival in June and the shortest in October.

5.0641, EFFECTS OF NUCLEAR ELECTROMAGNETIC PULSE (EMP) ON CIVIL SYSTEMS

D.B. NELSON, U.S. Atomic Energy Commission, Oak Ridge National Lab., *Oak Ridge, Tennessee* 37831 (W-7405-ENG-26)

Objective is to determine whether EMP can seriously affect the performance of vital civil systems during a nuclear attack, and if so to find appropriate countermeasures.

EMP, an intense pulse of electromagnetic fields accompanying a nuclear detonation, can induce large currents and associated voltages in cables or other conductors. It is known that malfunction or damage in unprotected electrical or electronic equipment can sometimes result.

The research program is largely theoretical, although some experiments have been performed. Elements involved include: the determination of electromagnetic field characteristics, studies of the coupling of field energy into various conductor configurations, characteristics and effectiveness of various protective devices and methods, susceptibility to damage of equipment, and resultant system performance.

5.0642, RADIATION RESPONSE OF A SUB S SPERMATOGONIA

E.F. OAKBERG, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

Identification of the A sub s (A-stem) spermatogonium has changed our concept of stem cell renewal, and bears not only on our understanding of cell differentiation, but also on our understanding of the effect of agents which affect fertility and mutation frequency. The use of long-term 3H-thymidine labeling in conjuction with radiation revealed a possible relationship between differential cell survival and the effects of both high doses and dose fractionation on mutation frequency. This experiment should be repeated, and the investigation extended to other radiation doses and dose rates.

Results: A sub s spermatogonia have been shown to be radiation resistant, and to be the only spermatogonial type surviving doses of over 100R. The data suggest that qualitatively, the spermatogonial population surviving 100 and 500R is the same, and that the kinetics of these cells for the 8.5 - 17 day post-irradiation interval is the same as for the A sub s cells in controls. Thus one can be more confident that extrapolation of the straight line portion of the mutation rate curve should not result in underestimation of the effect of low doses.

5.0643, RADIOSENSITIVITY OF IMMUNOCOMPETENT CELLS IN STATES OF FLUX

G.B. PRICE, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

The objective of this project is to determine if the radiosensitivity of immunocompetent cells changes when steady-state equilibrium is destroyed by radiation or altered by continuing senescence. Recovery of immunocompetence in mice after sublethal irradiation as measured by generation of hemolysin plaque-forming cells occurs over a period of weeks. The recovery is characterized by a decrease to a minimal level of immunocompetence followed by exponential and abortive phases leading finally to an overshoot and gradual return to steady-state equilibrium. Assessment of radiosensitivity of immunocompetent cells in these phases and in senescent mice will be accomplished by obtaining the D37 values for those cells.

Results: D37 values for immunocompetent cells in abortive and exponential phases of recovery following irradiation are not significantly different from the D37 value for immunocompetent cells in steady-state equilibrium.

5. RADIATION

SUPPORTED BY U.S. Atomic Energy Commission

5.0644, X-RAY-INDUCED DAMAGE TO THE DNA OF HAEMOPHILUS INFLUENZAE AND CELLULAR RESPONSE TO THAT DAMAGE

M.L. RANDOPH, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

Our ultimate goal is to determine the molecular mechanisms of the genetic effects of radiations. Using biophysical and genetic techniques, we compare and contrast results of X-ray and ultraviolet (UV) irradiations. 'Haemophilus influenzae' cells are being used as a test system in studies of X-ray irradiation of whole cells and of transforming DNA irradiated 'in vitro'. On the molecular scale, initial absorption of energy from ionizing radiations is random rather than by specific molecules, as is typical for UV radiations. Hence doing genetic experiments using transforming DNA first irradiated 'in vitro' simplifies any mechanistic interpretation by reducing the irradiated molecular species to that transforming DNA.

Results: X-irradiation of 'Haemophilus' cells produces single- and double- strand breaks in their DNA, post-irradiation loss of acid insoluble DNA, reduced DNA synthesis, and reduced colony formation. Kinetic models of enzymatic degradation of DNA after X-rays have been developed which account for observed plateaus of remaining DNA being greater than cell survival or the Poisson expectation of unbroken strands. X-ray inactivation of transforming DNA, unlike its UV counterpart, is caused primarily by reduced integration into the host genome. Single strand breaks are correlated 1:1 with loss of transformation. Hence single strand breaks rather than nucleotide damage, seem to determine X-ray inactivation of transforming DNA.

SUPPORTED BY U.S. Atomic Energy Commission

5.0645, UV REPAIR IN NORMAL HUMAN CELLS AND CELLS FROM XERODERMA PIGMENTOSUM PATIENTS

J.D. REGAN, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

We are pursuing studies on the induction and repair of ultraviolet radiation damage to the genetic material of human and other vertebrate cells. A major current emphasis of the studies is to characterize and delineate the molecular basis of human UV-sensitive genetic diseases. This goal has been achieved in one such disease, 'Xeroderma pigmentosum'. Similar studies with other UV sensitive human genetic diseases are continuing.

Results: In collaboration with the Biophysics Group we have now thoroughly characterized the normal hyman cell pyrimidine dimer excision system. The first enzymatic step in the excision repair system has been clearly delineated by measurements of the molecular weight of human cell DNA after UV irradiation by means of alkaline sucrose gradients. Initial chain breaks are made by the UV endonuclease enzyme which is the first step in the repair system. This enzymatic function causes a decrease in the molecular weight of the DNA after UV. Utilizing this method and the method of direct measurement of dimer excision we have studied 7 patients with the hereditary disease Xeroderma pigmentosum. The results of these studies showed that in this disease essentially no dimers were excised and essentially no chain breaks were seen in sedimentation studies of the cell's DNA after UV irradiation.

SUPPORTED BY U.S. Atomic Energy Commission

5.0646, HEMOPOIESIS AND RADIOSENSITIVITY

L.H. SMITH, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

The state of activity of hemopoiesis at the time of exposure to ionizing radiation appears to be related to radiosensitivity of mammals. The broad objective of the project is to relate changes in hemopoiesis with radiosensitivity of the mouse. Of the methods we have used to evoke a marked change in hemopoiesis, injection of phenylhydrazine is most interesting becauue the chemical not only accelerates erythropoiesis but also alters the LD 50/30. The basis for this alteration in radiosensitivity may involve changes in numbers or in radiosensitivity of hemopoietic stem cells or a stimulation of the reticuloendothelial system. To test these possibilities, changes in stem cell number are assessed by quantitative transplantation of isogeneic hemopoietic cells into X-irradiated mice. Proliferative potential or surviving stem cells are measured by 30-day survival, by ferrokinetic, by spleen colony, or by hematologic methods.

Results: Phenylhydrazine given to mice 1 or 2 days before or after irradiation reduced the LD 50/30 considerably. The reason for this reduction is unclear. The LD 50/30 is increased about 100 R, however, when the drug is given about one week before exposure. Concomitant with protection, there is an increase in stem cell number in the spleen but not in the bone marrow, and there is not an increase in radioresistance of hemopoietic cells.

SUPPORTED BY U.S. Atomic Energy Commission

5.0647, LATE EFFECTS OF EXPOSURE TO LOW AND MEDIUM LEVELS OF WHOLE BODY IRRADIATON IN MICE

J.B. STORER, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W)

The objective is to determine the relation of small doses of gamma radiation to shortening of life span and induction of neoplasms and other degenerative diseases, and to determine if the rate of irradiation (41 vs. 0.007 rad/min) changes the dose-response relation. At present it is difficult to estimate with confidence the shape of the dose- response curve for somatic effects at doses below about 100 rads. Yet, the chance of people being exposed to low doses appears to be increasing with the increased use of radioactive sources in power production, science, industry, and medicine. The experiment is presently divided into two phases: 1) Each week groups taken from a total of 120 ten-week-old mice were exposed to a single whole-body dose of 10 to 300 rad of gamma radiation at a rate of 40 rad/min. They are then maintained under rigorously controlled environmental conditions - to protect the mice from infectious disease and to reduce the influence of other variables since the difference in results for control and experimental mice are expected to be small. Most of the mice are allowed to live until death occurs naturally. Some of the mice are killed at weekly intervals from 12 to 120 weeks of age (Serial Sacrifice Group). All mice that die are examined by pathologists. The last of 15,000 mice in this phase were recently irradiated and the second phase was begun. 2) About 5000 mice, divided into two dose rate groups (40 and 0.007 r/min), will be handled essentially like those in phase one.

RESULTS: About 9,000 mice in phase one have died but it will take about two more years before the last mouse dies and the total data are available. Preliminary evaluation of the interim data, however, suggests that there may be a linear dose-effect down to the lowest dose tested - 10 rads. The problems in initiating phase two have been solved and it is well under way.

SUPPORTED BY U.S. Atomic Energy Commission

5.0648, THE CONTROL OF RESPIRATION IN UV-IRRADIATED BACTERIA AND ITS SIGNIFICANCE IN RECOVERY FROM RADIATION DAMAGE

P.A. SWENSON, U.S. Atomic Energy Commission, Ecological Sciences Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

Ultraviolet irradiation (UV) of 'E. coli' B/r cells grown on glycerol causes almost complete inhibition of respiration and growth for several hours beginning about 1 hour after UV. The cessation of respiration is dependent upon RNA and protein synthesis and is associated with the disappearance of pyridine nucleotides from the irradiated cells. Immediately after a UV dose of 500 ergs, mm2 survival is about 1%; beginning about 2 hours after UV, the number of viable cells in the culture increases exponentially. We are using this system to study the role of DNA in the control of respiration in irradiated cells and to determine the biochemical and physiological steps leading to death or survival. We have isolated several niacin-requiring mutants of B/r and will trace the fate of isotopically labeled pyridine nucleotides after UV irradiation. Our approach to the death-survival problem is to use physical and chemical post-UV treatments that promote respiration and see how survival and other parameters for the treated cells differ from the untreated ones.

Results: Post-UV treatment with heat (45 C for 30 min) and 5- fluorouracil both prevent the cessation of respiration and promote cell survival. Immediately after UV, all irradiated cells support growth of T-4 bacteriophage but after 2 hours only viable cells support this growth. Heat treatment and 5-fluorouracil increase markedly the capacity of irradiated cells to support phage growth.

5.0649, VIRUS ACTIVATION IN RADIATION AND CHEMICAL CARCINOGENESIS

R.W. TENNANT, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

It has been demonstrated that radiation-induced leukemia in C57BL and RFM mice is etiologically related to a specific class of viruses. It is uncertain, however, whether radiation acts to induce leukemia by: a) inducing proliferation of target cells susceptible to an indigenous leukemogenic virus or, b) that irradiation is capable of specifically activating the oncogenic potential of the virus or subcellular mechanism.

A means of distinguishing between these and some other alternatives is to determine if X-irradiation is able to activate viral synthesis in cultured cells, and then to determine whether the cells and/or the virus are leukemogenic. The same basic questions apply to neoplasms induced by chemical carcinogens. If the mechanisms of radiation and chemical carcinogens actually involve virus activation the most direct way in which this can be proven is with cloned cells in culture.

Results: The techniques necessary to assay murine leukemia virus synthesis and quantitate the number of cells in which the virus multiplies have been adopted. Experiments have been initiated to determine 'in vivo' the rate of viral 'activation' and the minimum dose of X-rays required. Other experiments have been initiated to test for activation of virus synthesis in cultured mouse cells. No results are yet available.

5.0650, PATHOGENESIS OF RADIATION INDUCED HEMOPOIETIC DEATH IN GNOTOBIOTIC MICE

H.E. WALBURG, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

Germfree (GF) mice exposed to radiation in the lethal range have only a slightly higher LD50/30 when compared to conventional (CONV) mice of the same strain. Since infection appears to play a major role in the death of irradiated animals, a sizeable increase in LD50/30 might have been expected. Since most of the GF mice die during the first two weeks following irradiation before the number of erythrocytes has been seriously reduced, anemia does not appear to contribute greatly to the death of the animals. Initial observations also suggest that hemorrhage is very much reduced in GF animals compared to their CONV counterparts. Although bone marrow replacement therapy is successful in preventing hemopoietic death in irradiated GF mice, it would appear that treated animals are not dying from absence of mature functional elements normally produced by the bone marrow. We have undertaken experiments to clarify the cause of death of lethally irradiated GF mice.

Results: Studies on the repopulation of the hemopoietic system in irradiated mice using organ uptake of 125IUDR suggested an effect of the microbial flora only as regards the rate of repopulation of the mesenteric lymph node. No evidence of defective repopulation of erythrocytic or granulocytic compartments was noted in GF mice. Studies on replacement therapy with mature cellular elements of the blood have been initiated.

5.0651, INFLUENCE OF THE MICROBIAL ENVIRONMENT ON AGING AND LONG TERM EFFECTS OF RADIATION

H.E. WALBURG, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

To determine the role of the microbial flora and fauna in aging and in the development of senescent lesions, germfree (GF) and conventional (CONV) irradiated and unirradiated mice are being examined with respect to their life span and incidence of disease. The data from these experiments should help define the influences of microbial environment on survival and help differentiate those pathological processes which are a response to the microbial flora from those caused by senescence of cellular and organ systems. These data will also permit the characterization of those specific diseases which are responsible for the life shortening effects of radiation in mammals. Mouse strains which have been or will be studied include those with short life span and specific cause of death and those with a long life span and nonspecific causes of death. Strains to be studied include non-inbred ICR and inbred RFM, AKR, C3H, DBA/2, and C57BL/6.

Results: In all strains studied to date, the mortality rate is lower in the germfree mice reflecting primarily a decreased mortality rate the first half of the life span. While most diseases that occur in CONV mice also occur in their GF counterparts, some neoplastic and non- neoplastic diseases occur with different incidences and different time of onset. Those diseases which are most affected by the microbial environment involve tissues of the host defense systems.

5.0652, RESPONSES OF PLANTS AND PLANT COMMUNITIES TO IONIZING RADIATION

J.P. WITHERSPOON, U.S. Atomic Energy Commission, Ecological Sciences Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

The major objective of this program is to provide an ecological assessment of the consequences of ionizing radiation on higher plants and plant communities. Experimentation with environmental and population variables that influence radiosensitivity is designed to provide both information on the detrimental effects of radiation and knowledge of how ecological systems function. At the species or population level growth chamber and green house facilities furnish means of controlling and testing ecological factors that interact with ionizing radiation to produce effects in natural assemblages of plants. An understanding of these interactions is prerequisite to interpretation and prediction of the consequences of radiation, or other man-made peturbations, in natural systems. The differential affects of several types of radiation are studied. Currently, information on radiosensitivity of native and agricultural plants to beta radiation is being compiled. In addition to providing new information on responses of plants to this particular radiation type, these studies should lead to the development of better radiological hazard assessments of nuclear weapons fallout. At the species level, studies on the effects of ionizing radiation on functional processes such as photosynthesis and nutrient transport continue to furnish parameters which can be used to assess ecological effects at a population or ecosystem level of organization.

Results: The interaction of sublethal ionizing radiation and light intensity on yellow poplar and silver maple tree seedlings adversely affected functional processes such as photosynthesis, root development and carbohydrate formation. Yellow poplar was more sensitive than silver maple but the survival capacity of both was reduced. The retention of particulate fallout simulants on plants depends more on species growth form and habits than the type and mode of fallout deposition. Chronic field exposure of fescue grass to 0.5 r/hr reduced seed production and germination significantly after a cumulative dose of 3000 rads.

5.0653, THE TIME COURSE OF RECOVERY FROM GAMMA RAYS AND FISSION NEUTRONS

J.M. YUHAS, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W)

The objective of the present study is to provide a theoretical model and its experimental verification for radiation injury appearance and disappearance in the multiple physiological systems of the mammal. The model which has been developed requires only simple dose versus survival time data, and it is amenable to

experimental alterations such as pre- and post-exposure conditioning. In addition, the method of analysis is applicable to retrospective studies on data previously obtained for many large mammals. The experimental verification of this method is split into two phases, the acute and late effects. For the analysis of acute effects, approximately 2000 LAF sub 1 hybrid mice will be exposed to graded doses of gamma rays or fission neutrons, with the doses spaced equally in terms of their reciprocal. The late effects portion of the verification will be obtained from extensive gamma ray and neutron studies. In brief, these studies will provide estimates of the late effects of these two radiations if delivered early in life (t sub 1) or later in life (t sub 2), or thoughout the t sub 1, t sub 2 interval (chronic or fractionated). Each of these responses should be predictable by the model.

RESULTS: In comparing the present model with those in the literature, three major advantages have been uncovered: greater accuracy, greater experimental flexibility, and greater usefulness in large animal analyses. For example, the present model has been applied to such diverse problems as hematopoietic recovery and chemoprotection in mice and radiation injury in cold-blooded vertebrates. In each case, the calculated recovery kinetics corresponded closely to those determined by extensive analyses of single injury modes, and provided new information on a variety of injury modes.

5.0654, LATE EFFECTS OF RADIATION AS A FUNCTION OF DOSE RATES BETWEEN 1 R PER DAY AND 1 R PER SECOND

J.M. YUHAS, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405)

The objective of the present study is to define the relationship between dose and dose rate and a variety of late effects of ionizing radiation. The study is essentially a factorial design with 5 total doses given at 1 of 8 dose rates to adult CAF1 hybrid mice. Not all cells of the experiment will be included; i.e. some which are known to be ineffective or maximum response points will be deleted. Approximately 200 mice will be placed in each cell. With appropriate spacing of doses and dose rates it will be possible to analyze the effects of dose rate at a given total dose, the effects of total dose at a given dose rate, the effects of exposure time on a given dose, and the effects of variable dose over a constant time. Samples of mice will be given similar total doses later in life, in order to provide estimates of latent period for expression of injury.

RESULTS: The mathematical development of a model on which this experiment is based has been completed, and is covered in another abstract (Yuhas and Darden: The Time Course of Recovery from Gamma Rays and Fission Neutrons) and the complementary fission neutron study is also covered elsewhere (Darden and Yuhas: Late Effects of Single and Fractionated Doses of Fission Neutrons and Gamma Rays).

5.0655, LATE EFFECTS OF LOW DOSE RATE GAMMA RAYS DURING THE PRENATAL PERIOD

J.M. YUHAS, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405)

The injury induced by radiation depends on the age or state of maturation of the host at the time of exposure. The foetal mammal is particularly sensitive to most forms of somatic injury which manifest themselves within a short period after irradiation, and the question immediately arises whether the extreme radiosensitivity of the foetus applies also to such late effects of radiation as life shortening and carcinogenesis. The experiments we are conducting will determine the late somatic effects of low dose rate gamma rays (approximately 1 R per 20 hour day) given during the preconception, foetal, post-natal, or young adult periods. These low radiation levels were selected in order to avoid 'artificial selection' of the experimental population through the induction of acute mortality and to provide exposure levels which would approximate those which might be received by the human foetus.

RESULTS: This is a new project that is just starting.

5.0658, METABOLISM OF TRACE ELEMENTS

M.C. BELL, Univ. of Tennessee, U.T. A.E.C. Agric. Res. Lab., *Oak Ridge, Tennessee* 37830 (AT-40-1-GEN-242)

The research in this phase is concerned primarily with effects of both external and internal beta and whole-body gamma irradiation on animal metabolism of minerals. This includes not only stable mineral elements but also the use of radioisotope tracer techniques. Emphasis is placed on the whole animal functioning as a coordinated unit to supply necessary data and guidelines for organ systems and detailed biological research. Species comparisons are made among those which are economically important to man as food and also among those similar to man in size and metabolic functions. Imbalance of food nutrients and interaction of radiation damage and metabolism of both nutrients and toxic ions are being investigated. Results from these data are of dual value to supply not only radiation biology data, but also essential information on animals which supply about 40 percent of the food energy and about 68 percent of the food protein in the human diet.

RESULTS: Feeding cattle and sheep 2 to 2.4 mCi Y90 labeled sand/kg of body weight increased in vitro Zn^{65} RBC uptake, increased plasma Cu and reduced plasma Mg and Ca. Irradiation of 8 to 12 percent of the skin from Sr90-Y90 sealed sources increased in vitro Zn65 RBC uptake, increased plasma Cu and decreased plasma Fe. Stable plasma Zn was only slightly altered and the Zn65 RBE uptake appeared to be associated with the development and recovery from the beta irradiation lesions. Whole body gamma irradiation had no measurable effects on these parameters.

SUPPORTED BY U.S. Atomic Energy Commission

5.0659, RADIATION STUDIES ON LIVESTOCK UNDER SIMULATED FALLOUT CONDITIONS

M.C. BELL, Univ. of Tennessee, U.T. A.E.C. Agric. Res. Lab., *Oak Ridge, Tennessee* 37830 (AT-40-1-GEN-242)

The research in this phase is designed to obtain information that is not available from the literature on the assessment of vulnerability of livestock production to fallout radiation. This will include research primarily on food-producing ruminant (cattle and sheep) livestock to determine the effects of gastrointestinal (GI) and skin beta exposures and the interaction of these with whole-body gamma irradiation. Limited studies are also proposed for swine. Over 80 percent of our ruminant livestock are continuously on grazing land throughout the year and could be exposed to ingested fallout, skin burns, and whole-body gamma irradiation. Data are needed on ruminants because they are important not only as a food reserve valued at over 18 billion dollars, but they also presently supply about one-fourth of the energy, one-half of the protein and three-fourths of the calcium to the U.S. diet. It is expected that radiation effects on livestock lethality, productivity, radiation insult interactions, gross and microscopic pathological changes and metabolic alterations will be studied in these irradiated animals.

Supported in part by funds from OCD through DBM.

RESULTS: Most of the sheep and cattle exposed to multiple modes of radiation died within 60 days. These simulated fallout radiation sources were: gastrointestinal tract radiation from feeding Y90 labeled sand; radiation of 8 to 12% of the skin using sealed Sr90-Y90 sources; and 240 R at 1 R/min whole-body gamma from 60Co. Deaths within 60 days from single sources was restricted to only a small percentage of those fed Y90 labeled sand. Anorexia, diarrhea and severe weight loss were the principal results from feeding Y90 labeled sand which caused severe damage in the rumen and abomasum. Skin irradiation reduced productivity while whole body gamma had no measurable effect on livestock productivity.

5.0660, EARLY EFFECTS OF 14 MEV NEUTRON IRRADIATION IN SWINE

D.G. BROWN, Univ. of Tennessee, U.T. A.E.C. Agric. Res. Lab., *Oak Ridge, Tennessee* 37830 (AT-40-1-GEN-242)

The purpose of this study was to obtain as much information as possible from a small number of swine on the effects of 14 Mev neutrons which would permit comparison of data of lower energy neutron and gamma radiations. The areas of study were the general clinical changes, hematology (complete blood counts), mortality and gross and microscopic pathology.

There was no information available on the effects of high energy neutrons on large animals of size comparable to man and the need for this information from the standpoint of human radiobiology stimulated the thoughts leading to this study. We were not aware of the possibility or feasibility of exposing swine to 14 Mev neutrons until we were invited by the Health Physics Division of the Oak Ridge National Laboratory, in the latter part of September 1968, to consider using the HENREE-II accelerator at the Nevada Test Site (NTS). The accelerator was scheduled to cease operation in December 1968, thus time was one of several factors which limited the scope and size (number of animals used) of the experiment.

RESULTS: The LD50(30), tissue dose-in-air, was calculated to be 498 rads (95% confidence limits equals 347-649 rads). Dose distribution was very uniform across the animals; thus, the LD50(30) midline absorbed dose was higher than the LD50(30) midline absorbed doses for fission neutrons and Co60 gamma radiation. The higher midline dose, perhaps, contributed to the more severe signs of gastrointestinal damage in the swine exposed to 14 Mev neutrons. The primary cause of death, however, appeared to be due to damage to the hematopoietic system.

5.0661, LATE EFFECTS OF WHOLE-BODY GAMMA AND MIXED NEUTRON-GAMMA IRRADIATION ON LARGE ANIMALS

D.G. BROWN, Univ. of Tennessee, U.T. A.E.C. Agric. Res. Lab., *Oak Ridge, Tennessee* 37830 (AT-40-1-GEN-242)

Late effects of gamma and neutron-gamma irradiation of burros are being studied. Emphasis is principally on longevity and detection of physio-pathological changes which can be attributed to or associated with irradiation damage. Each animal is subjected to thorough physical and laboratory examination twice yearly. The major portions of these studies have been in progress for more than twelve years.

Data pertaining to late effects of irradiation on long-lived animals are relatively sparse compared to that of short-lived small laboratory animals; thus, data from studies such as these are necessary to bridge the gap between short-lived animals and man. In addition to the need for information on large animals from a human radiobiology standpoint, there is need for knowledge of irradiation effects on food- producing animals which is essential not only in dealing with emergencies, but also with animal management in the event a large percent of our livestock population is affected.

RESULTS: The rate of mortality among the irradiated burros has been much higher than in the controls. Blood dyscrasias, particularly thrombocytopenia have been observed frequently in the irradiated prior to death. The clinical and pathological findings have been similar in the gamma and neutron-gamma irradiated survivors and decedents. The lesion of greatest significance was the decreased number of megakaryocytes in the bone marrow which corresponded in severity to the clinical thrombocytopenia. Life shortening, based on current data, was estimated to be less than 4%/100 R in the gamma-irradiated and less than 7%/100 rads in the bomb-irradiated burros.

SUPPORTED BY U.S. Atomic Energy Commission

5.0662, LATE EFFECTS OF WHOLE-BODY GAMMA IRRADIATION ON THE WORK PERFORMANCE AND RELATED PHYSIOLOGY OF SHETLAND PONIES

D.G. BROWN, Univ. of Tennessee, U.T. A.E.C. Agric. Res. Lab., *Oak Ridge, Tennessee* 37830 (AT-40-1-GEN-242)

The objective of this study is to evaluate the physical fitness of Shetland ponies which recovered from early effects of whole-body gamma irradiation by subjecting the ponies to work assignments and measuring various physiological changes which occur during exercise.

Studies dealing with effects of exercise on animals surviving irradiation have been limited mostly to small laboratory animals and to the period immediately after irradiation. Little is known about the physical capabilities of large, long-lived animals surviving radiation exposures. The data from this study will contribute to an estimate of the physical capabilities of man following exposure to ionizing radiation.

RESULTS: This experiment has been in progress for more than three years. During the interim the irradiated ponies have performed their work assignments with equal efficiency to that of the nonirradiated controls. Significant differences (P less than 0.05) between irradiated and nonirradiated ponies have been observed in heart rate, respiratory rate and rectal temperatures. Change in ambient temperature appears to affect the irradiated more than the controls.

SUPPORTED BY U.S. Atomic Energy Commission

5.0663, THE EFFECT OF INTENSITY OF 60CO GAMMA RADIATION ON THE EARLY MORTALITY OF SWINE

D.G. BROWN, Univ. of Tennessee, U.T. A.E.C. Agric. Res. Lab., *Oak Ridge, Tennessee* 37830 (AT-40-1-GEN-242)

Irradiation studies with large animals have been limited and little is known about the effect of dose rate. A range of LD50/30 values has been reported for burros and swine exposed to several sources of ionizing radiation and under various field and laboratory conditions. Several variables inherent in each of the experiments from which the lethal values were derived (type of radiation, quality of radiation, minute intensity, and age and size of animals) presumably influenced the mortality response. The contribution of each variable to the mortality response cannot be quantitated from the data available. Dose rate was one of the factors which varied considerably among the experiments reported on swine and appeared to affect the mortality. The highest LD50/30 value was observed at the lowest dose rate and the lowest LD50/30 value was observed at the highest dose rate.

In view of the need in human radiobiology for useful data on animals of sizes similar to man and the increasing use of swine in experimental radiobiology, it has become more imperative that a quantitative analysis of certain variables such as dose rate be undertaken. The purpose of this experiment was to determine the LD50/30 for swine at various intensities while minimizing other variables as much as was feasible.

RESULTS: The LD50/30 values calculated from the data were 717, 433, and 355 R, respectively, for 1, 10 and 50 R/min. The LD50/30 midline exposure doses measured in a 114 kg swine cadaver were approximately 455, 275, and 225 R, respectively. The relative effectiveness of 10 and 50 R/min were 1.65 and 2, respectively, where 1 R/min was assigned the value of 1.

5.0664, CONTROL AND MODIFICATION OF SEED RADIOSENSITIVITY

B.V. CONGER, Univ. of Tennessee, U.T. A.E.C. Agric. Res. Lab., *Oak Ridge, Tennessee* 37830 (AT-40-1-GEN-242)

5. RADIATION

The major objectives of this program will be to study (1) the influence of various modifying factors, such as oxygen, water content, temperature, etc., on the radiosensitivity of seeds from a wide range of plant species to both sparsely and densely ionizing radiation and (2) the relationship between radiosensitivity of seeds of different species and nuclear factors, such as nuclear volume, interphase chromosome volume, DNA content per nucleus, and DNA content per chromosome in the cells of the embryonic shoot apical meristem. From results of these studies we hope to extend our knowledge of basic mechanisms by which sparsely and densely ionizing radiation induce biological damage in the resting seed.

Seeds are the most frequently used plant part of mutagenic treatment. The advantages of using seeds are that large numbers of relatively uniform individuals can be treated and transported conveniently under conditions which can be precisely controlled and reproduced.

RESULTS: A post-irradiation oxygen effect (OER the difference between 1.3-1.4) has been demonstrated for neutron irradiation of very dry barley and rice seeds. This effect disappears in barley seeds as the water content is increased to a difference of 10 percent. Seeds of different species appear to differ greatly in their response to oxygen treatment following gamma irradiation. For example, OER values range from 1.2 for onion to 13 for rice.

5.0666, EFFECTS OF RADIATION ON THE REPRODUCTIVE SYSTEM

B.H. ERICKSON, Univ. of Tennessee, U.T. A.E.C. Agric. Res. Lab., *Oak Ridge, Tennessee* 37830 (AT-40-1-GEN-242)

Quantitative and qualitative aspects of the evolutionary pattern of the germ cell and associated gonadal structures are being determined within the bovine and porcine species. As specific areas of change are delimited, radiation is administered and its effects are determined both through quantitative and qualitative microscopic analyses of gonads excised at varying times after irradiation and through semen and steroid anayses, where applicable. Since our studies have demonstrated that individuals within the large-animal species vary widely in their basic germ-cell endowment, increased emphasis is being placed on determinations of the ultimate effects a given dose of irradiation has upon lifetime reproductive capacity. In these studies, the technic of unilateral castration (ovariectomy and orchidectomy) is being employed. Not only does this reduce the amount of time necessary to complete an experiment, but in addition, each animal can serve as its own control.

RESULTS: Following doses (50 R/minute) of 82 plus or minus 5, 140 plus or minus 5 and 220 plus or minus 5 rads absorbed by bovine testes aged 20 to 30 days (N equals 10) germ-cell numbers were reduced to 21 plus or minus 2% of control, but level of cellular survival did not differ between doses (P less than 0.01). Also, level of germ-cell survival (21 plus or minus 1% of control) did not differ (P less than 0.05) in testes irradiated (82 to 220 rads) at ages varying from one to 60 days of age, but the number of germ cells per 600 tubular cross- sections increased (P less than 0.01) from 204 plus or minus 36 in day- 60 testes (220 rads) to 468 plus or minus 36 in testes irradiated when 90 plus or minus 5 days of age (210 rads).

SUPPORTED BY U.S. Atomic Energy Commission

5.0667, EFFECTS OF RADIATION ON LIFETIME REPRODUCTION

B.H. ERICKSON, Univ. of Tennessee, U.T. A.E.C. Agric. Res. Lab., *Oak Ridge, Tennessee* 37830 (AT-40-1-GEN-242)

The objectives of this study are to determine the effects of varying levels of acute total-body irradiation on 1) fertility and longevity of cows, 2) viability and growth performance of their calves, and 3) long-term pathological response of the survivors.

Sexually mature females were exposed at varying doses up to 400 R single exposure and 600 R in a fractionated double exposure. Two hundred and nineteen of those animals surviving beyond the first 30 days after irradiation are being maintained for their reproductive life.

RESULTS: Neither birth weights nor weaning weights (7 months of age) of calves from irradiated dams has been affected. Also, number of live-births per cow, through seven gestations, has been unaltered by irradiation, even though only 68 percent of the cows (controls and irradiated combined) gave birth to a calf during the past year. Percent of cows surviving to date is as follows: Control - 90; 200 R - 85, 300 R - 68, 400 R - 75 and 300 R plus 300 R - 82.

5.0668, PATHOLOGY

D.F. JOHNSON, Univ. of Tennessee, U.T. A.E.C. Agric. Res. Lab., *Oak Ridge, Tennessee* 37830 (AT-40-1-GEN-242)

The program of radiation pathology is primarily devoted to interpretation of pathological alterations in organs and tissues of animals subjected to various forms, doses, and sources of ionizing radiation. Cadavers are subjected to gross examination, and the samples of tissues taken from them are subsequently reviewed microscopically.

Necropsies and histopathological perusals are not, however, performed solely on cadavers and tissues from animals utilized exclusively for radiological experimental purposes. A variety of conditions and etiological factors are found in relation to deaths in unallocated animals. The observations made concerning many of these cadavers are as important as those rendered in regard to the individuals used for experimental purposes.

Such activities are conducted with the aid of the usual tools employed by the pathologist. These consist of the post-mortem laboratory and instruments, the histotechniques laboratory, histochemistry and conventional microscopy.

RESULTS: In recent years, attention has been directed principally toward detailed studies of long-term survivors of ionizing radiation. Gross studies have been completed on some cattle, sheep, and swine; histopathological evaluation of many of the tissues from these animals is now being conducted. Macroscopic and microscopic perusal of tissues from surviving burros and cattle is still in progress.

5.0669, EFFECTS OF PRENATAL IRRADIATION ON GROWTH

P.G. MARTIN, Univ. of Tennessee, U.T. A.E.C. Agric. Res. Lab., *Oak Ridge, Tennessee* 37830 (AT-40-1-GEN-242)

Growth retardation in rats as a result of prenatal irradiation has been well documented. A gross picture of weight differences may be obtained by considering body and organ weights, but if cell numbers and cellular materials are determined, the reason(s) for smaller animals along with the pattern of growth may be investigated. The rat progresses through three phases of growth which gradually merge from one to the other. Growth due to hyperplasia, hyperplasia plus hypertrophy, and hypertrophy may be followed by determining total DNA (cell numbers) and cellular materials in the organs that are of interest.

Whether growth depression due to irradiation during gestation is a combination of initial cell death, reproductive death or to damage to growth regulating organs that are involved in hormonal secretion or regulation of protein synthesis are areas to be investigated. Several workers have reported impaired enzyme function in the liver of prenatally irradiated animals as a result of radiation insult to the hypothalamus-hypophysis area. Others have shown impaired protein synthesis in the total fetus irradiated between the 14th-16th days of gestation. The impairment of these systems at suboptimal levels would prevent cell division 'from proceeding at a normal level and growth retardation would be the outcome.'

RESULTS: The smaller organs from the irradiated animals are due to fewer cells per organ rather than difference in RNA and protein per cell. The response of liver and kidney from the irradiated animals during the postnatal period, 1-160 days of age, indicates fluctuations in cell numbers in relation to controls ranging from 56 to 84%. The recovery of the thymus and spleen from the irradiated males was similar to adult response to irradiation of these organs and reflects the predominant haemopoietic cells found in that organ. Growth hormone injections in young irradiated males resulted in weight increase ranging from 8-20% over irradiated controls.

5.0670, TISSUE CULTURE STUDIES IN LARGE ANIMALS

A.F. MCFEE, Univ. of Tennessee, U.T. A.E.C. Agric. Res. Lab., *Oak Ridge, Tennessee* 37830 (AT-40-1-GEN-242)

Irradiation damage to chromosome structure and induced changes in cell behavior are being evaluated through the in vitro culture of peripheral blood leukocytes from domestic animals. The favorable number and morphology of the pig's chromosomes and the ease with which their cells grow in culture make this the most desirable of our species. Other species and other cell systems are employed when needed for special purposes or for verification or species comparison. Several parameters of leukocyte behavior in culture are being examined in order to determine whether changes may occur which are well correlated with radiation dose and more eadily measured than the chromosome abrerration rate. Emphasis is placed on the relationship between in vivo and in vitro exposures of cells in an attempt to avoid the necessity of exposing the entire animal in order to evaluate his response to irradiation. We are also exploring the relationship between chromosome damage in somatic cells and that induced in the male germ cells.

RESULTS: Chromosome damage after exposure to 14 MeV neutrons was significantly higher following 'in vitro' irradiation than that found in cells taken from the same animals immediately after a similar exposure. Correlations between dose and aberration rates were sufficiently high with both 'in vivo' and 'in vitro' exposures to permit the development of a formula for predicting 'in vivo' chromosome aberrations from the rate obtained for an 'in vitro' irradiated blood sample. The lower 'efficiency' of neutrons for producing 'in vivo' breaks suggests some protective mechanisms in the 'in vivo' system.

SUPPORTED BY U.S. Atomic Energy Commission

5.0671, RADIOIODINE AND LARGE ANIMALS

J.K. MILLER, Univ. of Tennessee, U.T. A.E.C. Agric. Res. Lab., *Oak Ridge, Tennessee* 37830 (AT-40-1-GEN-242)

Iodine is of interest both as a necessary dietary trace element and as a potential irradiation hazard. A knowledge of iodine metabolism and effects of I131 thyroid damage is important in the dairy cow, the domestic milk producing animal of greatest economic importance, because of the intimate relationship function lactation. Results obtained with other species do not always apply to cattle because of large quantitative species differences. Current objectives include study of: 1) forms in which iodine exists in the digestive tract and circulatory system and factors influencing absorption and excretion of iodine; 2) interrelationships among various iodine concentrating systems including the thyroid, mammary gland, salivary glands, gastric stomach, placenta, and kidney; and 3) effects of partial thyroid destruction by acute I131 doses on iodine and calcium metabolism and performance, including growth, reproduction, and lactation. Partial thyroid destruction has been produced in one member of each of nine pairs of identical twin heifers by single doses of 100 to 180 muCi I131 per Kg body weight. Calcium-thyroid interactions have been investigated in a total of 33 calves and 12 mature cattle. All cows except one thyroid damaged cow which failed to breed have completed the second lactation, ten cows have completed the third, and one pair has begun the fourth lactation.

RESULTS: Thyroxine replacement therapy was begun for thyroid damaged cows during the second month of the second lactation and continued through the third. Milk yield, body weight, and heart rate of thyroid damaged cows, expressed as percentages of their control twins, averaged 52, 103 and 86, respectively, during the first lactation; 58, 89 and 89 thyroxine therapy in the second; 62, 85 and 111 after thyroxine therapy in the second; and 91, 88 and 103 during the third lactation. Animals with I131 thyroid damage or normal animals fed thiocyanate show decreased ability to clear intravenously administered stable or radio calcium. Thyroxine therapy appears to correct this condition.

5.0672, EFFECT OF DOSE RATE AND TOTAL DOSE OF GAMMA IRRADIATION UPON METABOLIC PARAMETERS IN BIRDS

F.R. MRAZ, Univ. of Tennessee, U.T. A.E.C. Agric. Res. Lab., *Oak Ridge, Tennessee* 37830 (AT(40-1))

Developmental stages of animals are usually more sensitive to irradiation than the adult. The chick embryo being divorced from its mother, permits a closer examination of radiation injury to developing tissues. Therefore, White Leghorn eggs will be irradiated by gamma rays at each of the following dose rates: 1/4, 1/2, 1, 2 and 4 R/hr during the entire incubation period except for 1/2 hour/day. The effect on mortality, growth rate, length of time to sexual maturity of females, egg production, fertility and hatchability of their eggs and growth and reproductive performance of their progeny will be ascertained by a comparison with controls.

The effect of dose rate at maturity upon the progeny of the irradiated hens will be determined using the same parameters. A minimum of 30 White Leghorn hens will be exposed to a total gamma ray dosage of 800 R at each of the following dose rates: 1, 5, 25 and 45 R/min and compared to controls.

White Leghorn chickens at varying ages will be exposed to 800 R from gamma rays at a dose rate of 1 R/min. At intervals after irradiation Ca45, Sr85 and P32 will be orally administered or perfused into the small intestine to assess the effect of radiation upon intestinal absorption, blood levels and tibia deposition of these nuclides.

RESULTS: Mature White Leghorn, Coturnix and Bobwhite Quail females were exposed to various combinations of rate of exposure and total dose levels of whole body gamma irradiation. The irradiated birds laid significantly fewer eggs than the control groups during the first ten- day period following exposure. Total dose seemed more important than rate of exposure. Coturnix and Bobwhite females were less sensitive to the lethal effect of whole body gamma irradiation than White Leghorn females.

5.0673, THE METABOLISM OF STRONTIUM AND RELATED NUCLIDES IN POULTRY

F.R. MRAZ, Univ. of Tennessee, U.T. A.E.C. Agric. Res. Lab., *Oak Ridge, Tennessee* 37830 (AT(40-1)GEN-242)

The fate of strontium in poultry with special reference to its role in the metabolic pathways and their interaction with similar nuclides is our major concern. The mechanisms of discrimination at interfaces of organs, cells and cellular particulates during vital life processes will be investigated. The information obtained in these studies is useful in understanding the relationship of fission products to essential minerals and thereby developing countermeasures to fission product contamination and in understanding aberrations in mineral metabolism.

Strontium and its relationship to calcium and phosphorus in the small intestine of White Leghorn hens are now being studied. Perfusions of the small intestines with varying levels of Ca, Sr and P and their radionuclides coupled with differential centrifugation of the mucosal cells of the small intestines and uteri are being applied. The effects of low dose rate (1 R/min) of externally emitted gamma irradiation (800 R) on the absorption of these elements by White Leghorn chickens utilizing both oral dosing and perfusion are also being studied at different periods after irradiation.

RESULTS: The perfusion of the small intestines of White Leghorn hens (with an egg 'in utero') with varying levels of Ca and Sr revealed a decrease in the Sr85 Ca45 ratios from 0.8 at absorption to 0.5 at the egg shells. The radionuclide contents and

Sr85: Ca45 ratios in the cellular particulates of the small intestine and uterus decreased as particulate size decreased. The presence of Sr without Ca tended to increase Sr85; Ca45 ratios and increase their content in the jejunal and ileal mitochondria. Ca alone brought the ratios closer to unity and reduced the effect of Sr in combination.

5.0674, THE EFFECT OF RADIATION ON PRENATAL DEVELOPMENT

R.L. MURPHREE, Univ. of Tennessee, U.T. A.E.C. Agric. Res. Lab., *Oak Ridge, Tennessee* 37830 (AT-40-1-GEN-242)

This phase of our studies is concerned with the effects of dose- rate (gamma radiation from Co60 on the teratogenic response in prenatally irradiated lambs, pigs and rats. Major emphasis is being placed on exposure at developmental stages previously demonstrated to be quite sensitive to radiation. Previous findings have shown that irradiation of lambs on the 23rd-25th days and of pigs on the 20th-21st days of gestation resulted in malformed limbs. No other organ systems have consistently been effected in either species. In rats, the frequency of malformed eyes following exposure on the 11th day and testicular damage following exposure on the 18th day of gestation are the endpoints being used for dose-rate studies in this species.

It now appears that there is a definite dose-rate response in the pig and rat, whereas, the situation in the lamb is equivocal. Future efforts will be directed toward a better characterization of the dose and dose-rate response within and between species.

RESULTS: The effect of a 100 R dose delivered on the 11th day of gestation at rates of 1, 2, 3, 4, 5, 10, 25 and 47 R/min. on eye anomalies in rats has been studied. Frequency of abnormal eyes increased with rates of 1 to 3 R/M reached a maximum at 3 to 10 R/M and appeared to decrease slightly after 47 R per minute.

5.0675, METABOLIC EFFECTS OF GASTROINTESTINAL AND SKIN RADIATION INJURY

L. WADE, Univ. of Tennessee, U.T. A.E.C. Agric. Res. Lab., *Oak Ridge, Tennessee* 37830 (AT-40-1-GEN-242)

The gastrointestinal syndrome has long been recognized as the result of large doses of X- or gamma-irradiation and the histological changes which occur, particularly in the small intestine, are well documented. Less is known about the metabolic changes produced by radiation injury to the gastrointestinal tract, particularly in large mammals. Although skin erythema was one of the first types of radiation injury to be studied, research related to radiation damage to this organ, like that of the GI tract, has been focused primarily on histological changes. Radiation damage to either of these areas may produce serious alterations of the metabolic processes, which though not fatal themselves, may be contributing factors in hematopoietic radiation death or have a deleterious effect on the long term health of the animal. Development of methods to measure damage to the skin and gastrointestinal tract would be useful in determining the relative biological effectiveness of neutrons for damage to these organs.

Results: Concentrations of iron, copper and zinc in the plasma and erythrocytes, uptake of Zn65 by erythrocytes, plasma protein concentration, and routine hematology are being measured on 8 control sheep and 8 sheep given 25,000 rad beta radiation to the skin. The irradiated areas are routinely photographed in order to follow the sequential development of irradiation lesions. Changes in the platelets, plasma iron, plasma copper, are the most consistent indicators of radiation damage to the skin.

5.0676, SPECIES COMPARISON OF THE ACUTE IRRADIATION SYNDROME

L. WADE, Univ. of Tennessee, U.T. A.E.C. Agric. Res. Lab., *Oak Ridge, Tennessee* 37830 (AT-40-1-GEN-242)

Detailed studies of the acute radiation syndrome have been carried out primarily in small laboratory animals because of ready availability, low cost, and ease of maintenance. Although interpretation of experimental data obtained from one species to predict response to another species is always difficult, there is increasing evidence to indicate that the response of larger mammals to radiation may differ from that of smaller mammals. Direct experimentation in humans is impossible, but a comparison of the acute radiation symdrome in several large mammalian species offers hope for obtaining an understanding of the basic mechanism involved. This type of understanding is difficult to achieve, however, when the distribution pattern of radiation dose is such that several organs are affected at the same time, and lethality is the primary end-point measured. This project will be designed to develop methods other than lethality for studying the acute radiation syndrome, and to compare the effects of acute radiation injury in different species.

Results: Preliminary experiments on iron kinetics have been initiated in sheep and swine.

5.0677, PHYSICO-CHEMICAL STUDIES OF RADIATION EFFECTS IN CELLS

E.L. POWERS, Univ. of Texas, School of Arts, *Austin, Texas* 78712 (AT(40-1)-3408)

The aim generally is recognition of physical states and chemical species intermediate between the absorption of radiant energy and the exression of biological damage in cellular systems. The modification of water content, water structure, and the presence and absence of chemical and physical modifiers allow separation of damage into a number of independently acting components. The work in the next few years will involve UV effects of several kinds. The changes in sensitivity to 254 nm have been observed as water content of spores changes, and as oxygen is removed. The chemical consequences of these wild be studied. Also, dose rate of the UV in some spore stocks is an important physical determiner of sensitivity. In these stocks it is now Bnown that continuous vs. interrupted beams of UV give different results, and a formal study of this phenomenon is under way. In all these regular analyses of photo products will be attempted. High pressures of inert gases modify radiation sensitivity in the spore in a manner depending upon water content. This study will be extended to mammalian cells.

SUPPORTED BY U.S. Atomic Energy Commission

5.0678, PHYSICO-CHEMICAL STUDIES ON IRRADIATED CELLS

E.L. POWERS, Univ. of Texas, School of Arts, *Austin, Texas* 78712

Objective: The overall objective is to recognize the early events that are important in the induction of damage in cells exposed to high- energy radiation. The end-point for many years has been the death of the cell; now, the mutation process has been added. We attempt to accomplish the aim by using cells that can be exposed to varied and extreme environments without harm so that physical and chemical experiments that have known consequences in in vitro experiments can be done with the cell with a biological end-point as the measure.

5.0680, RADIATION EFFECTS ON MATURE CHICKENS
W.C. BANKS, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (TEX01338)

OBJECTIVE: Compare results from 2 different types of radiation, that is a neutron-gamma mixture as opposed to just gamma.

APPROACH: At the completion of studies of gamma ray radiation on chickens it was noted that the expected decrease in fertility and egg production did not occur. On the contrary, survivors showed an increase in production over the non-irradiated controls. This is at variance with mammalian studies. It is proposed to procure 200 young chickens and at maturity, and following usual blood studies, to irradiate them with sub-lethal doses of radiation using the nuclear reactor for the source of ionizing radiation. The chickens will be maintained and matings allowed for production and fertility studies. In addition, we would like very much to know if a different kind of radiation will continue to show the marked difference in sex susceptibility between male and female chickens.

PROGRESS: The original research was completed and accepted by the U.S.A.E.C. and the T.A.E.S. An adjunct was suggested and approved. The purpose was to compare radiation effects of chickens exposed to the nuclear reactor compared to chickens that had been exposed to cobalt 60 radiation. The lethality studies were not conclusive and showed variation in death losses at different levels instead of an increasing percentage at higher levels. However, interesting results were produced in hatchability and egg production in chickens exposed to different levels of radiation. Following are results after 82 days post radiation exposure for egg production and hatchability, respectively: Control (non irradiated, 67.9% and 80.3%; House 01 - 200r, 300r, 400r survivals, 70.8% and 87.4%; House 02 - 500r, 600r, 700r survivals, 67.3% and 77.6%; House 03 - 800r, 900r, 1000r survivals, 68.9% and 89.3%.

5.0681, DELAYED SENSORY EFFECTS OF PRENATAL IRRADIATION
S.O. BROWN, Texas A & M University System, School of Science, *College Station, Texas* 77843

The purpose of this investigation is to supply knowledge concerning the delayed effects of continuous, low level and acute prenatal irradiation on delayed sensory capacity. Five groups of Spanish goats are given irradiation during gestation: Group I 521.5R; Group II 1043R at the continuous low dose rate of 0.17R hour 0.35R hours respectively, and Group III 521.R and Group IV 1043R acutely (200R minute).

Upon reaching maturity all subjects will be given conditioned avoidance training in order to establish a conditioned foreleg flexion response to a broad range of conditioned stimuli. It has been established that such conditioned responses provide reliable indices of sensory capacity when used in conjunction with the method of limits. The sensory modalities to be tested are: (1) Audition (loudness and pitch thresholds), (2) Vision (brightness and critical-flicker-fusion thresholds), and (3) cutaneous (Vibratory and temperature thresholds).

Group I and II are being trained and tested and Group II receiving 1043R at 7R daily show important sensory losses. The animals of Group III receiving 521R in acute doses are approaching maturity while Group IV receiving 1043R did not survive the radiation treatment.

The program is proceeding with all testing systems functional.

5.0682, THE ROLE OF LIGHT AND TEMPERATURE IN THE GROWTH AND DEVELOPMENT OF PLANTS
R.D. POWELL, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (TEX01127)

Objective: Obtain further information about the quanlitative and quantitative effects of light and the possible interrelationship of radiation and temperature in controlling vegetative and reproductive responses of selected plants. Determine the effect of temperature and light on: vegetative growth: flower formation; fruit set; study the interaction of red and far-red light with gamma-radiation and plant growth regulators on the photomorphogenetic response of plant tissue.

Progress: 1. Boll set in cotton is impaired by high night temperature. This result is brought about by a failure in pollen development. 2. Chilling injury can be demonstrated in leaf tissue from cotton plants. This effect is not related to moisture stress. There appears to be little effect on cell membranes. 3. Okra plants are severely damaged by chilling at 50 F. This response occurs at both low and high humidity.

5.0683, INFLUENCE OF PHYSICAL STATE OF CHROMATIN ON NUCLEIC ACID & PROTEIN SYNTHESIS & ON RADIATION SENSITIVITY OF CELL DIVISION
M.E. GAULDEN, Univ. of Texas, School of Medicine, *Dallas, Texas* 75230 (AT(40-1))

This study is concerned with cell division and the effects of radiation on it. Attention is focused on the relation of chromosome condensation and extension during the cell cycle to nucleic acid and protein synthesis and to radiosensitivity. Data are collected by direct observations on dividing neuroblasts in cultures of the grasshopper embryo and by autoradiographs of the observed cells. Two agents known to affect the physical state and progression of chromosomes have been chosen for study, namely, colchicine and culture medium of increased or decreased ionic strength. The amount of unscheduled DNA synthesis (radiation-induced thymidine uptake in non-S phases) in individual cells will be compared to the extent of a radiation effect, i.e., inhibition of prophase progression.

Results: Colchicine over a 10,000-fold range of concentration affects the rate at which neuroblasts reach metaphase; both inhibition and stimulation of rate occur. These are accompanied by morphological changes in the changes in the chromosomes of telophase, interphase and prophase. The extent of colchicine effects are a function of concentration and exposure time. Radiation-induced tritiated thymidine uptake has been shown to occur only in those prophase cells (non-S) that revert to interphase. Uptake is enhanced by growing the cells in hypotonic culture medium.

5.0685, PHOTOREPAIR OF UV DAMAGE TO DNA - PURIFICATION & PROPERTIES OF THE DNA-PYRIMIDINE DIMER PHOTOMONOMERASE (ABBREV)
H. WERBIN, Univ. of Texas, School of Medicine, *Dallas, Texas* 75230 (AT(40-1))

Man's ecological environment is influenced by the interaction of sunlight on biomolecules, for example, in the induction of smog, vitamin D in the skin, photosynthesis and diurnal rhythms in plants and animals. We have purified 70,000-fold from cell-free extracts of yeast, one of these molecules, the DNA-pyrimidine dimer photomonomerase, heretofore called, the DNA-photoreactivating enzyme, that requires light to carry out its function, repair

of UV-damaged DNA. The ultraviolet absorption and fluorescent spectra indicate association with the enzyme of a chromophore involved in photoreactivation. We propose to continue the purification until the enzyme is obtained homogeneous. Then we will attempt to dissociate the enzyme into the apoprotein portion and the chromophore. The physical and chemical parameters of the latter will be examined, such as molecular weight, sedimentation constant, amino acid analysis and amino acid composition of binding sites. The chromophore will be concentrated, separated, isolated and its structure determined. By understanding the interaction of sunlight on the biosphere, we can more intelligently counter those of its interactions that are harmful to man.

Results: The DNA-photoreactivating enzyme has been purified 70,000-fold by affinity chromatography on irradiated DNA-cellulose. Only one major protein impurity remains to be eliminated in order to obtain a homogeneous enzyme preparation for further studied. Like the algal enzyme, the yeast enzyme was found to be reversibly inactivated by ferricyanide. The enzyme preparation showed a peak in its UV absorption spectrum at 380 nm and the same maximum in its excitation spectrum. A maximum in its fluorescence spectrum was at 470 nm. These data indicate that the chromophore involved in photoreactivation has been uncovered.

5.0686, RESPONSE OF SKIN TO MONOCHROMATIC LIGHT

J.M. KNOX, Baylor University, School of Medicine, *Houston, Texas*

This project is designed to study the effects of monochromatic light on skin. Several approaches are being used to study the effects of ultraviolet, visible and infra-red on various biological systems, including microorganisms, tissue culture cells, laboratory animals and human volunteers. The response of normal skin and cells to threshold and larger injury doses of ultraviolet are being studied. The action spectrum for cutaneous carcinogenesis is being determined. The effects of photosensitizing drugs on various biological systems are utilized to attempt to elucidate site of action and mechanisms of photosensitization with different agents and in naturally-occurring photosensitivity reactions. Other studies include the effects of environmental conditions on ultraviolet injury and a series of studies designed to measure the effects of atmospheric and environmental conditions on the solar spectrum.

5.0687, BIOCHEMICAL CHANGES IN SKIN INDUCED BY IRRADIATION

E.W. RAUSCHKOLB, Baylor University, School of Medicine, *Houston, Texas*

Previous studies have shown that ultraviolet (UV) light markedly reduces the levels of cholesterol in human skin. Explanations for this phenomenon have centered upon either direct effects of light, per se, on the sterol moeity or a light-induced imbalance between sterol anabolism and catabolism. We have demonstrated that short-term, broad spectrum radiation induces structural changes in the sterol nucleus in both buffered biological systems as well as in aqueous emulsion under the same experimental conditions to which skin had been exposed in previous experiments. Using a monochromatic light source, wave lengths of 265 nm were found most effective in altering the sterol molecule. Because large reductions in the cholesterol levels of skin briefly exposed to UV radiation should not be expected to result from effects on the rate of synthesis, the possibility remains that the previously observed reduction in cholesterol levels of UV exposed skin was due to direct alteration of the molecule by light.

An investigation of the effects on skin of broad spectrum light, in which wavelengths below 290 nm were excluded, revealed that the incorporation rates of C14-acetate into the total lipid, free sterol, neutral fat, and phospholipid fractions were lowered. Parallel studies on skin obtained from swine indicated that reduced levels of incorporation of acetate into the various classes of lipids were the result of altered synthesis and not due to reduced precursor uptake, increased lipid breakdown, or direct effects of light, per se, on the lipid moeities.

Further studies with human skin demonstrated that the light susceptible site of sterol synthesis lies along the biosynthetic pathway between acetate and mevalonate. Our data suggest that light interferes with sterol synthesis prior to acetyl Coenzyme A (acetyl CoA) and probably involves the activation of acetate or the availability of acetyl CoA pools of size sufficient to sustain sterol synthesis.

5.0688, BIOCHEMICAL CHANGES IN SKIN INDUCED BY IRRADIATION

E.W. RAUSCHKOLB, Baylor University, School of Medicine, *Houston, Texas*

A systematic investigation into the biochemical alterations produced by sunlight and ultraviolet light irradiation on human, intact skin presents a challenging research problem in the basic sciences and in dermatology. There are numerous studies describing morphologic, gross and microscopic, changes as well as histochemical alterations subsequent to the skin's exposure to ultraviolet light. However, biochemical analyses of the major epidermal components remain limited.

The following research problem is designed to permit a more comprehensive, better controlled investigation of alterations in skin constituents as related to irradiation exposure. In particular, careful attention will be given to biochemical modifications which may give some clue to the mechanisms in re 1) the capacity of irradiation and environmental factors to injure skin with the ensuing production of erythema, inflammatory response, promotion of pigment formation, acceleration of degenerative changes and of premature aging, 2) the relationship of ultraviolet light to photosensitivity and its role in precipitating or aggravating systemic diseases such as lupus erythematosus, pellagra, porphyria and photosensitization phenomenon associated with certain drugs, 3) the influence of sunlight and ultraviolet light on enzyme activity and the formation of substances with potent biochemical and physiological actions both beneficial (e.g. formation of Vitamin D) and deleterious (e.g. formation of premalignant and malignant skin morphology).

Hopefully the research project will contribute to a better understanding of the complex subject of photobiology.

5.0690, FACTORS INFLUENCING LD50, LD100 AND PRENATAL RADIATION INJURY

H.L. BARTON, U.S. Veterans Administration, Hospital, *Houston, Texas* 77031

The preparation of facilities to accommodate the breeding and maintenance of specific Pathogen Free (SPF) mice has been completed at the Animal Research Facility. A working laboratory, an SPF mouse room and an X-ray room are set up and have been prepared to maintain an active level of investigation in the area of mammalian radiobiology.

Calibration of the 220 kVp x-ray machine has been completed and data is available on the variation in output with changes in field size, filtration, target distance and operating parameters. An X-ray beam shutter has been fabricated to allow precise determination of exposure. Uniform mouse irradiation will be insured by the use of a variable speed turntable that can accommodate up to 15 mice per irradiation.

The fogging and decontamination procedure to prepare Room 7 in the Animal Research Facility for habitation by SPF mice has been completed. A representative of Center Chemical

Co. supervised the use of the disinfectant chlorocide which was used for the fogging and the subsequent decontamination procedures. The area has been routinely cultured and any area showing possibility of contamination is again scrubbed down with the disinfectant and re-cultured until clean.

All sterile supply items such as masks, gowns, boots, gloves, (for investigators), and animals supplies such as bedding and food are placed into the room for use as needed.

There are ten male and ten female Balb/c mice in the Laboratory. These animals represent the nucleus of the breeding group that will be maintained under rigid control to insure the quality of the inbred strain. Under continuing development are breeding procedures, cytogenetic techniques and irradiation methods.

5.0691, CYTOGENETIC INJURY IN X-RAY IRRADIATED MICE

H.L. BARTON, U.S. Veterans Administration, Hospital, *Houston, Texas* 77031

Project No. 39-68 has completed two major experiments during the past year and has several additional studies in progress. The completed studies dealt with methodology associated with the analysis of chromosome aberration in mouse bone-marrow cells. Variations in the time of application and the concentration of the mitotic arresting drug colchicine were evaluated in order to determine the optimum time/concentration for obtaining the maximum number of clear and well- spread chromosome plates in both unirradiated and irradiated mice. Another study has been completed that was designed to show the variation in the intensity of cytogenetic damage as a function of post-irradiation time. The data, however, have not been completely evaluated.

Several studies are in progress. One is a collaborative effort with Dr. Donald Wilhoit of the University of North Carolina. He is irradiating mice with a prescribed protracted or fractionated radiated scheme and is evaluating the mean survival time for these mice. We are determining the cytogenetic damage in hopes of correlating this information with mean survival time. Exposures in our mouse colony are in progress to determine the relationship between cytogenetic damage and acute lethality in X-irradiated mice. Another study is in progress to evaluate the relative biological effectiveness of californium-252 compared to radium-226. Mice are irradiated with one or the other of these radiation sources in a specially-fabricated irradiation jig, and the cytogenetic damage is evaluated. A study to determine the extent of cytogenetic damage, if any, in newborns following prenatal pelvimetry examination is in progress. This work is in collaboration with Dr. Angel Werch of the Department of Obstetrics and Gynecology.

SUPPORTED BY U.S. Veterans Administration

5.0692, BIOCHEMICAL EFFECTS OF RADIATION ON INTACT HUMAN SKIN INCUBATED IN VITRO

E W. RAUSCHKOLB, U.S. Veterans Administration, Hospital, *Houston, Texas* 77031

Previously we reported from this laboratory ultraviolet light induces reduction in the level of cholesterol in human skin. It was observed that short-term, intense broad spectrum radiation induced structural changes in the sterol nucleus both in serum and aqueous emulsions. Approximately 50% of cholesterol-4-14C in the aqueous emulsion was converted to more polar photoproducts in 10 minutes and some of the radioactivity appeared as a gas. Although the identity of the volatile products in the experiments remains to be determined, involvement of the fourth carbon of the A ring on the parent molecule is requisite. The results of these experiments do not eliminate the possibility that a light catalyzed degradation of cholesterol occurs in vivo. However, the rapid effect of light on aqueous emulsions of the labelled sterol suggested direct action on the cholesterol moiety.

In an effort to further characterize the conditions under which the sterol was destroyed, the wavelengths involved were determined by use of ultraviolet grating filters and monochromatic light. When filters, which transmit only visible wavelengths longer than 330 nm, were employed no alteration of the sterol occurred. A spectrograph of the light source used in the experiments indicated the wavelengths responsible for the photoaction on cholesterol. Following exposure to the respective energy levels, about 37% of the cholesterol was altered at 254 nm. At 6000 mj/au squared about 22% of the cholesterol was altered at 254 nm.

The next step was to investigate the effect of ultraviolet light upon lipid synthesis de novo. Skin biopsy specimens from volunteers were subjected to radiation using a Xenon light source yielding radiation comparable to sunlight; non-irradiated specimens served as controls. The incorporation of the label into lipid fractions was determined by chromatographic techniques. The results indicate 1) that non-irradiated skin specimens synthesize lipid, including cholesterol, at a rate equal to that of liver parencyma and 2) that exposure to ultraviolet light inhibits total lipid synthesis which includes phospholipids, sterols, (cholesterol) neutral fats and triglycerides. In recently conducted experiments it appears that ultraviolet light interferes early in the synthetic pathway of sterol synthesis from acetate to cholesterol. (Text abridged).

5.0694, RADIATION AND BIOPHYSICAL STUDIES ON VIRUSES AND CELLS

A. COLE, Univ. of Texas, Graduate School of Medicine, *Houston, Texas* 77025 (AT(40-1))

The objective is to determine the structure of mammalian chromatin and chromosomes and the mechanisms of radiation action in this organelle. Such studies are central in understanding radiation effects in cells. Isolated mammalian deoxyribosenucleic acid (DNA), histones, nucleoproteins, chromosomes, and whole cells are utilized to investigate chromosome damage, single and double strand DNA scission and repair, helix denaturation and other radiation effects. The observations utilize analytical and preparative ultracentrifugation, stereo electron microscopy and optical detection of thermal denaturation. Effects of gamma rays and californium-252 neutrons will be compared. The location of radiosensitive sites within the cell is studied using partly penetrating electron and heavy particle beam irradiations.

Results: Deproteinized mitotic chromosomes extend to hundreds of micrometers and appear to contain about 64 parallel DNA molecules. Irradiation of cells or isolated chromosomes produces single and double strand DNA breaks. For moderate doses (several breaks per molecule), the average energy expended within the DNA molecule per break is about 50 eV for single strand breaks, 600 eV for double strand breaks in mitotic cells or chromosomes, and 2,000 eV for double strand breaks in interphase cells. Single strand breaks can be repaired by the cell; double strand break repair remains questionable. Strand breakage of naked DNA in solution appears to be indirect. At concentrations of 0.3 mg/ml and dose levels that produce about five breaks per molecule less than 0.03 eV is expended directly within the DNA per single strand break and less than 0.4 eV per double strand break. A 12 to 70 fold protection against breakage is observed if the DNA is first complexed with various histone fractions. The particle beam studies implicate a thin radiosensitive region near the nuclear membrane in interphase cells and a more diffuse region near the chromosomes in mitotic cells.

5.0695, LONG-TERM EFFECTS OF INTENSE SPECTRAL LIGHT EXPOSURE ON PRIMATES
H.G. SPERLING, Univ. of Texas, School of Medical Sciences, *Houston, Texas* 77025

It has been shown that prolonged exposure to intense spectral light produces very long-term, perhaps permanent changes in the spectral sensitivity of primate eyes. The effects coincide in the spectrum with prominent features of the photopic foveal spectral sensitivity function which has been related to the absorption spectra of the cones. The effects of blue light amount to a 90% reduction in sensitivity over the blue region, and have lasted over one year with no effect outside the blue or in the unexposed eye.

This program will continue to study this phenomena in two directions. First, psychophysiological studies will be conducted with increasingly intense spectral lights from argon and krypton ion lasers in order to ascertain the nature of the effect in the green and red regions of the spectrum, to explore the intensity-time relationships for producing the effect, and the recovery time to different durations, intensities, and wavelengths.

Second, histological studies will be conducted in an effort to ascertain the nature of the effect, and if successful, efforts will be made to make statistical estimates of the population of the three classes of cones as a function of degree of functional loss.

SUPPORTED BY U.S. National Science Foundation

5.0696, THE RADIOBIOLOGY OF NORMAL TISSUES
H.R. WITHERS, Univ. of Texas, Graduate School of Medicine, *Houston, Texas* 77025

A microcolony 'assay' system has been used to measure survival of intestinal mucosal cells from irradiation. Intestinal crypt stem cells are capable of accumulating and repairing large amounts of sublethal X- or gamma-radiation injury. Even after doses of 850 rads the capacity for sublethal damage is not saturated. This capacity is less when irradiation is with 14MeV monoenergetic neutrons and very small or absent when exposure is to 252 californium fission neutrons.

The response of crypt cells to irradiation depends on their position in the division cycle at the time of irradiation. The results of experiments in which hydroxyurea was used to induce synchrony within crypt stem cells suggest that late S-phase is the most resistant.

5.0697, EFFECTS OF X-IRRADIATION ON THE HUMAN TESTIS - AN ELECTRON MICROSCOPE CYTOCHEMICAL STUDY
J.D. BERLIN, Texas Technological University, School of Arts, *Lubbock, Texas* 79409 (AT(40-1))

Normal human testes which have received X-irradiation doses of 20, 75, 200, and 600 r will be subjected to an electron microscopic cytochemical examination to determine the effects of irradiation on the subcellular structure and function of the testis. The testis is an extremely radiosensitive tissue. An early irradiation effect is the breakdown of spermatogonial cells which leads to azoo-spermia. The reappearance of the spermatogenic cell series marks the beginning of the recovery process, however, the timing of complete repopulation of the seminiferous tubules is dose dependent and may require several years for high doses. In addition to these morphological events, it has been suggested that irradiation may alter the localization of various enzymes. We will examine biopsies obtained from a few minutes to several months after irradiation to define changes that occur in the subcellular structure and in enzymic localizations during spermatogonial degeneration and the recovery process. Our results with the irradiated material will be compared with that we have found to occur in normal, non-irradiated human testes. The enzymes to be examined include acid phosphatase, thiamine pyrophosphatase, glucose-6-phosphatase, inosine diphosphatase, and various other nucleoside di- and triphosphatases.

Results: In normal human testis Sertoli and spermatogenic cells we found glucose-6-phosphatase in the endoplasmic reticulum (ER), thiamine pyrophosphatase in the Golgi complex (GC), inosine diphosphatase in the ER and GC, and adenosine mono- and tri-phosphatases on the plasma membrane. Acid phosphatase was present in the lysosomes of the Sertoli cells. After irradiation, we observed an increased activity for acid phosphatase and thiamine pyrophosphatase, a decreased activity for glucose-6-phosphatase, and no change in the activities of adenosine mono- and triphosphatases.

5.0698, EFFECTS OF IRRADIATION UPON AIRCREW EQUILIBRIUM
D.J. BARNES, U.S. Air Force, School of Aerospace Med., *San Antonio, Texas* 78235

Early transient incapacitation (ETI) has been observed in trained primates exposed to acute, high doses of weapons radiation. The mechanisms concerned are unknown, however the decrement is sufficient to cause mission failure where continuous performance is required. The objective is to evaluate the effects of pulsed fission-spectrum radiation upon crewman's ability to perform complex flight functions dependent upon visual and proprioceptive integrity. Stimulus and response characteristics are designed to be complementary to man's behavior in an operational environment.

5.0699, RADIATION EFFECTS ON CREW-TYPE MULTIPLE TASKS
D.J. BARNES, U.S. Air Force, School of Aerospace Med., *San Antonio, Texas* 78235

Technical Objective: Trained primate performance decrement has been observed following weapons radiation exposure. The injury mechanisms are unknown and the effects on the visual, auditory and motor systems have not been adequately determined. The objective is to evaluate these systems post exposure by using a standardized multiple avoidance program (MAP) which simulates pilot visual, auditory and motor performance. This task can also be used to evaluate special radiation stresses such as nanosecond, flash X-ray exposures which may be encountered in the operational environment.

SUPPORTED BY U.S. Dept. of Defense - Air Force

5.0700, RADIATION ALTERED AIRCREW TRACKING ABILITY
D.J. BARNES, U.S. Air Force, School of Aerospace Med., *San Antonio, Texas* 78235

Technical Objective: Radar operators, offensive and defensive weapons systems personnel, navigators, and other aircrew members will engage in the continuous performance of monitoring and tracking signals on a cathode ray tube (CRT). The disruption of this behavior by radiation injury will have serious effects upon mission completion probabilities. Knowledge of the cardiovascular changes associated with such disruption is vital to both the treatment and prevention of performance decrement due to radiation. The objective of this work unit is to ascertain the relationship between the cardiovascular parameters of brain blood flow, blood pressure, and heart rate and the ability to perform a continuous operationally-relevant task in a radiation environment.

5.0702, EFFECTS OF IRRADIATION ON COMBAT CREW TASK COMPLEXITY
G.C. BROWN, U.S. Air Force, School of Aerospace Med., *San Antonio, Texas* 78235

It is operationally important to differentiate between simple motor behavior and the more cognitive (reasoning) elements of decision making in evaluating man's relationship in weapons systems S/V analysis. The objective of this effort is to delineate radiation response as a function of task complexity. The radiosensitivity-task relationship in primates can then be used to predict man's capabilities in a comparable environment.

5.0703, PATHOLOGICAL RESPONSES TO SELECTED AEROSPACE ENVIRONMENTS
C.G. HUIZENGA, U.S. Air Force, School of Aerospace Med., *San Antonio, Texas* 78235

Technical Objective: In selected aerospace operations, personnel are required to perform in or near environments that present potential medical hazards. Laser energy, ionizing radiation, extremely high altitudes, mixed gas atmospheres, toxic substances, and infectious agents, all common to various Air Force operations, may produce detrimental effects in man. This defines the pathologic effects of these environments, thus providing suitable data for safe exposure limits and/or the development of therapeutic treatments.

SUPPORTED BY U.S. Dept. of Defense - Air Force

5.0704, BIOLOGICAL EFFECTS OF RADIATION EXPOSURES FROM LONG DURATION FLIGHTS AND REPEATED MISSIONS IN LOW DOSE LEVEL ENVIRONMENTS
J.H. KIRK, U.S. Air Force, School of Aerospace Med., *San Antonio, Texas* 78235

Aircrews will be exposed to prolonged, low levels of radiation from fallout in nuclear warfare and in future operations involving very high altitudes, nuclear propulsion and isotope power sources. Little is known about the effects of low dose continuous radiation on man's performance and decision making abilities. In order to evaluate sub- clinical injury, new sensitive endpoints must be developed and special technics applied to define the low dose rate injury mechanisms. Neutrons, X-rays, electrons and protons will be studied using realistic dose rates ranging from rads per hour to rads per day. Long research and development lead time is needed for this type of biological study to provide essential mission planning data when new systems become operational.

SUPPORTED BY U.S. Dept. of Defense - Air Force

5.0705, RADIATION PRODUCED BRAIN INJURY - AIRCREW PERFORMANCE DECREMENT
M.A. NATHAN, U.S. Air Force, School of Aerospace Med., *San Antonio, Texas* 78235

Technical Objective: January 1970-March 1971. performance decrement has been consistently observed in trained primates exposed to weapons radiation. Since performance is dependent on the central nervous system (CNS) a temporary loss of consciousness and/or alteration of brain function can result in mission failure. This effort will investigate radiation injury to the brain and to systems supporting the brain.

SUPPORTED BY U.S. Dept. of Defense - Air Force

5.0706, LASER DAMAGE THRESHOLDS IN LIVING CELLS FOR OPERATIONAL SAFETY CRITERIA
J.E. PRINCE, U.S. Air Force, School of Aerospace Med., *San Antonio, Texas* 78235

Technical Objective: Permissible exposure levels for Air Force use have been extrapolated from animal data and are based on minimum visible ophthalmoscopic and histological changes. Uncertainties in extrapolation of animal data to humans and possible damage at the cellular level have necessitated the use of possibly excessive safety factors. The objective of this effort is to evaluate human cell response to laser radiation. Data collected from these studies will aid in establishing permissible exposure levels. Additionally, data from these studies will aid in understanding the mechanism of laser biological damage.

SUPPORTED BY U.S. Dept. of Defense - Air Force

5.0707, THE EFFECTS OF RADIATIONS ON THE GENETIC SYSTEMS OF ORGANISMS IN RELATION TO THEIR PHYSICAL AND BIOCHEMICAL SYSTEMS
M.L. ALEXANDER, Southwest Texas State Univ., School of Science, *San Marcos, Texas* 78666 (AT(40-1))

The investigations are designed to study the mutagenic process for induction of genetic mutations. The induction of delayed mutations with chemical and X-radiation and the effect of dose fractionation on the mutagenic process are the primary objectives of the research program.

The genetic system of Drosophila will be utilized for measuring sex-linked recessive lethals, delayed sex-linked recessive lethals, autosomal recessive lethals and visible mutation at specific loci. The specific projects include: 1) Mutagenic effect of DNA feeding, 2) The induction of delayed mutations in spermatogonial cells with X-radiation, and 3) Mutation rates at specific gene loci with continuous and fractionated doses of X-radiation.

Results: 1) Degraded DNA (tetra-nucleotides) will not be mutagenic if the highly polymerized form is not mutagenic; 2) The contribution of delayed mutations to the overall mutation recessive lethal rate is under investigation; 3) The data for continuous and fractionated doses of X- radiation are not extensive enough to compare the dose rate effects at present.

5.0709, SOME INTERNAL AND EXTERNAL FACTORS WHICH DECREASE OR INCREASE THE SENSITIVITY AGAINST RADIATION
A. SENGUN, Cekmece Nucl. Res. & Tr. Ctr., *Istanbul, Turkey*

1. The toxic effect of the radioprotector, AET on the rat embryonic cells grown at tissue culture by plating technic will be determined. For experimental purposes, the highest non-toxic dose of AET will be used. 2. The effect of AET on DNA, RNA, and protein synthesis of embryonic cells will be determined by the

use of tissue culture technics and tritiated thymidine, tritiated uridine and tritiated glycine or leucine. 3. The effect of AET, added prior irradiation to the cells, on the viability of the irradiated cells (by Co-60) will be determined. 4. The effect of AET on DNA, RNA, and protein synthesis of irradiated cells will be investigated.

For (1) and (3) Dose Effect curves will be prepared.

For (2) and (4) the autoradiograms of the cells will be prepared. The per cent labelling and the amount of grains in the labelled cells will be determined.

If time permits, the same experiments will be repeated with another radioprotector, cysteamine.

5.0710, THE RADIOSENSITIVITY OF MAMMALIAN GERM CELLS

H.M. BEAUMONT, Univ. of Birminghan., *Birmingham, England, United Kingdom* (AT(30-1)3846)

Our experiments are designed to examine the effects of irradiation on oocytes as judged by (a) changes in populations of ovarian oocytes and (b) the ability of oocytes to develop after fertilization; and to define and investigate factors influencing the radiosensitivity of oocytes.

It has been established that the radiosensitivity of oocytes differs within and between species: quantitative studies of the ferret, guinea pig and neonatal rat are in progress. Changes in the fine structure of oocytes after irradiation are being examined in the monkey and rat, two species whose oocytes differ markedly in their response, those in the monkey being much more resistant to the lethal effects of irradiation.

We have recently demonstrated that changes in the hormonal environment affect the radiosensitivity of oocytes in the rat. This study is continuing in order to define which of the gonadotrophic and/or gonadal hormones is effective.

The processes of spontaneous and induced atresia amongst oocytes are being investigated to see whether there is any evidence that atresia represents a 'selection' process, only those oocytes which are genetically fit and capable of giving rise to normal zygotes usually surviving to ovulation.

Factors underlying the onset of infertility in senile mice will also be investigated.

Results: We have demonstrated that hormonal factors influence the radiosensitivity of oocytes: those in hypophysectomized rats are much more resistant and/or take longer to be eliminated after exposure than oocytes in the unoperated animal. Administration of exogenous gonadotrophin reverses the effect of hypophysectomy.

5.0711, DEOXYCYTIDINE LEVELS IN URINE AND PLASMA AS AN INDEX OF IONIZING RADIATION DOSE

I.V. CHAPMAN, Univ. of Dundee, *Dundee, Scotland, United Kingdom*

Initially an attempt will be made to develop a method for determining microgram quantities of deoxycytidine in urine and plasma samples from human patients.

Investigations will be initiated into the influence of X-ray therapy of CdR levels in the samples indicated above. It is proposed that loading studies will be carried out with selected patients in an attempt to highlight metabolic changes resulting from exposure to X-rays.

Loading studies will also be carried out with mice. It is suggested that theresults from this species are more easily related to man than those from rat because of the levels of deoxycytidine aminohydrolase in the liver.

Radiotracer studies, involving H3 and C14 labelled deoxycytidine will be carried out to investigate pool size changes, biological half-life and turnover time in rats and mice.

SUPPORTED BY Intl. Atomic Energy Agency - Austria

5.0712, RADIOSENSITIVITY OF GENETIC STRUCTURES AND MOLECULAR BASIS OF RELATIVE BIOLOGICAL EFFECTIVENESS OF RADIATIONS OF DIFFERENT QUALITIES

G. NEARY, Medical Res. Council, *Harwell, England, United Kingdom*

In order to attack the general problems indicated in the Title of the Project, attempts are being made to obtain information on the quantitative and qualitative nature of the damage to radiosensitive structures in cells at three levels, namely, the instantaneous lesions first produced by the radiation, the fixed lesions which result from metionic reactions of the instantaneous lesions, and the permanent lesions which are not repaired or by-passed by the biochemical machinery of the cell. The influence of radiation quality (including interactions between radiations of different qualities) and of modifying treatments, at all three levels of lesion production in cells of various degrees of inherent radiosensitivity are being examined.

The radiobiological systems used continue as before: strand breakage in DNA in vitro and in vivo, chromosome aberration production in plants and in animal cells in culture, mutation and cell-killing in yeast and bacterial cells.

The radiations include charged particles of defined energy and LET and monochromatic X rays of low quantum energy.

Attention is being given to the perturbing effects of radiation on the kinetics of a population of dividing cells, using relatively simple populations in 'Tradescantia' and 'Campelia' anthers; such disturbances are particularly important in potential distortion of dose-response curves for chromosome aberrations. These studies will help in the interpretation of data for more complex cell systems.

5.0713, THE AGE FACTOR IN RADIATION SENSITIVITY OF MAMMALS

J. ROTBLAT, Saint Barthol. Hosp. Med. Col., *London, England, United Kingdom*

The mechanism of tumour induction following radiation will be continued with reference to the effect of age on the proliferative and adaptive characteristics of the cell populations of the normal tissue, compared with cell kinetics and possible feedback mechanisms in pre- neoplastic and gross neoplastic lesions of the same tissues.

The mechanisms of leukaemia induction at different ages and the effect of the development or regression of leukaemia on the normal bone marrow and spleen stem cell population will be studied.

In the lung parenchyma, where normal cells kinetics are presently being measured at different ages, under resting, compensatory or stimulated conditions, the cell kinetics, preferential site of growth, and population characteristics of lung tumours will be studied in the normal and radiation-injured lung, with or without urethane.

In the ovary the work on the interaction of oocyte number and total hormonal interplay on the yield and type of tumours following radiation or urethane will be continued.

5.0714, PULSE RADIOLYSIS OF NUCLEIC ACID DERIVATIVES

C.L. GREENSTOCK, Mount Vernon Hospital, *Northwood, England, United Kingdom*

Pulse radiolysis is being used as a tool to investigate fast chemical reactions occurring in dilute aqueous solutions of nucleic acid derivatives irradiated by microsecond pulses of ionizing radiation from a linear accelerator.

Any transient species having an optical absorption different from the parent solute molecule is detected and followed kinetically by means of a photomultiplier detector and oscilloscope.

Earlier studies by the author showed that the three primary species formed in the radiolysis of water (aqueous electrons, protons, and hydroxyl ions) attach nucleic acid bases, particularly pyrimidines, to form transient species or adducts. These very reactive adducts undergo a series of reactions to form stable changed or damaged molecules. The yields of these changed molecules are a measure of the radiosensitivity of the irradiated molecules.

One of many methods in radiation chemistry of modifying this radiosensitivity is by 'electron transfer', in which the electron is transferred from a potentially damaging site on the solute molecule to an added electron acceptor molecule, thus effecting a rapid 'repair' process.

Electron transfer will be studied initially between nucleic acid derivatives and later extended to other important biochemicals.

5.0716, THE EFFECTS OF X-IRRADIATION ON STEROID BIOTRANSFORMATIONS BY TESTICULAR TISSUE

L.C. ELLIS, Utah State University, Graduate School, *Logan, Utah* 84321 (AT(11-1))

Studies are being undertaken to ascertain what specific enzymatic steps and how sensitive these steps in the synthesis of androgens are to in vitro and in vivo X-irradiation. The changes in androgen synthesis will be correlated with specific aspects of the radiation syndrome to determine whether they reflect changes in naturally occurring radioprotective mechanisms of the organism or whether androgen synthesis is a factor that contributes to radiation sickness. Pineal function is being evaluated after irradiation to determine what relationship this gland has to testicular function as it relates to changes in the testis after irradiation. Naturally occurring radioprotective compounds are being evaluated to determine their relationship to radioprotection of the testis and to the effects these compounds have on testicular function. Radioprotective systems within the testis are being evaluated to ascertain how they relate to the changes in radiosensitivity of the testis that are known to occur with age. Histological data are being correlated with the biochemical data to determine what relationship exists between androgen synthesis, its metabolism, and the destructive and regenerative changes that occur after irradiation.

RESULTS: Androgen synthesis and its metabolism by rat testicular has been observed to correlate with histological changes in the germinal epithelium. Melatonin synthesis by the pineal gland has been observed to be altered after irradiation and these changes correlate with histological and endocrine changes in the testis. Lipid peroxidation and prostaglandins have been implicated in normal testicular function and alterations in testicular function after irradiation.

5.0717, THE RESPONSE OF HIGHER PLANTS TO ULTRAVIOLET LIGHT AND OTHER STRESS FACTORS

F.B. SALISBURY, Utah State University, Agricultural Experiment Sta., *Logan, Utah* 84321 (UTA00729)

OBJECTIVE: Study ultraviolet light as a stress factor including a continuing search for resistant species, studies of the mechanisms of damage and of resistance to ultraviolet light with emphasis on biochemical features of resistance. Study low temperature as a stress factor.

APPROACH: Ultraviolet light as a stress factor. Plant species will be screened to determine their resistance to UV light using a germicidal UV lamp and a xenon arc lamp. The mechanisms of damage by and resistance to UV light will be studied by kinetic approaches to the photochemistry and biochemistry of response to such light. UV effects on enzymatic reactions will be investigated. Low temperature as a stress factor. Winter cereals as well as native alpine species will be studied in the mountains, at the Blue Creek farm, and in the laboratory. Enzyme activity as a function of temperature will be emphasized.

PROGRESS: Studies on UV light were continued but deemphasized. Previous work was submitted for publication. A new postdoctoral fellow (Manfred Weidner) and a new graduate student began on the project. One year of observation of plants growing under snow was completed, and another field project was initiated, this one including some experimental approaches (shading, heating, insulating plots under snow) and accurate measurement of light penetration of the snow, using a trench dug before snowfall. Laboratory studies on plant growth at low temperatures were initiated, including enzyme and electronmicrograph research. Studies on heat transfer between the leaf and its environment were continued and accelerated somewhat.

5.0718, THE EFFECT OF INTERNAL EMITTERS ON THE HEMATOPOIETIC SYSTEM

J.H. DOUGHERTY, Univ. of Utah, School of Medicine, *Salt Lake City, Utah* 84112 (AT(11-1)119)

The hematological changes following a single intravenous injection of a wide range of doses of several internal emitters Ra226, Pu239, Ra228 (MsTh), Th228 (RdTh), Sr90 Ra 224 and Am241 into adult beagles have been followed for 18 years. The general aim of this study was to evaluate the relative toxicity of these radionuclides to the hematopoietic system. The blood picture is followed at closely spaced intervals for the life span of each animal in order to determine when hematological changes occur. The greatest effect is on leukocytes and platelets with depression of red cells only at highest dose levels.

SUPPORTED BY U.S. Atomic Energy Commission

5.0719, ASSESSMENT, EVALUATION AND CONTROL OF RADIATION EXPOSURE TO MAN AND HIS ENVIRONMENT - EXPOSURE TO EXTERNAL AND INTERNAL RADIATION

T.F. DOUGHERTY, Univ. of Utah, School of Medicine, *Salt Lake City, Utah* 84112 (AT(11-1)-119)

Studies of internal irradiation constitute the research efforts of this project. Biological effects of Ra226, Pu239, Ra228 (mesothorium), Th228 (radiothorium), Am241 and Sr90 are compared. The basic study was initiated in 1950. A large amount of data has been amassed and it is currently being analyzed. The skeleton is the principal site of deposition for the above-mentioned radionuclides which are administered as a single intravenous injection into young adult beagles at approximately 16 months of age. A wide range of dose levels varying from permissible body burdens to cancerogenic levels are studied with comparable controls.

The objective is to relate the onset and/or development of the various biological effects as a function of radiation dose and time. Whole body counting, radiochemical analyses and autoradiography are used extensively to obtain radiation dose rate information. Biological studies include clinical observations, radiological studies to document the changes in the skeleton, histo-pathology of bones, teeth and various soft tissues. Extensive hematological and blood chemistry studies are made. Principal cause of death is osteogenic sarcoma, a finding in general agreement with the observations made on humans exposed to Ra226. Liver and skeletal damage are the principal result of exposure to radionuclides which are deposited primarily in the skeleton. Current data are available in our annual progress reports.

SUPPORTED BY U.S. Atomic Energy Commission

5.0720, 239-PU RETENTION IN THE CHINCHILLA

R.D. LLOYD, Univ. of Utah, School of Medicine, *Salt Lake City, Utah* 84112 (AT(11-1)-119)

The metabolism and biological effects of internally-deposited plutonium have been studied in mice, rats, dogs, and other animals because of the importance of estimating the hazards of 239 Pu for man. Chinchillas are long-lived mammals that metabolize radium in a similar fashion to the human. Six of these animals were injected with 239 Pu in citrate buffer as a comparison with our previous extensive studies in beagles. During the first 21 months after injection, plutonium retention in these animals could be characterized by a sum of 2 exponentials, such

that 63 percent was retained as if it had a biological half-time of about 11 days and 37 percent had a half-time of 1475 days. In 2 animals dying 142 and 168 days after injection, about 85 percent of the retained plutonium was in the skeleton, 9 percent in the liver, and 6 percent in other soft tissues. Plutonium retention in the chinchilla appears to be lower than that in the dog, and the proportion of retained activity in the liver is less than either the dog or the human.

SUPPORTED BY U.S. Atomic Energy Commission

5.0721, PB-210 STUDIES IN BEAGLES

R.D. LLOYD, Univ. of Utah, School of Medicine, *Salt Lake City, Utah* 84112 (AT(11-1)-119)

The metabolism and effects of internally-deposited Pb and Pb-210 are becoming more important. Environmental Pb contamination is being given deserved attention, elevated Pb-210 levels in the Arctic are being studied in relation to the entry of radioactive Pb into human food supplies, and residual pb-210 burdens in uranium miners are being investigated as an indication of past exposure to radon and radon daughters in mine atmospheres.

To obtain metabolic data in large mammals, a few young adult beagles were injected with Pb-210 in citrate buffer. Retention was determined by total-body counting. In a typical beagle, injected Pb-210 was retained as if 36 percent had a biological half-time of 4 days, 43 percent had a half-time of 33 days and 21 percent had a half-time of 990 days for the first 1000 days after injection. The excretion was mainly fecal with about 3/4 of the total excreated Pb-210 appearing in the feces during the first 3 weeks. Pb-210 levels in the blood remained relatively high: the fraction of injected activity still circulating was 0.40 at 1 days, 0.14 at 1 week, and 0.03 at 1 month. One dog sacrificed 28 days after injection had about 63 percent of the retained Pb in the skeleton, 20 percent in the liver, 8 percent in the blood and 9 percent in other soft tissues. Liver had the highest Pb-210 concentration of any tissue measured, 1.6 times that in the skeleton.

5.0722, 241-AM METABOLISM AND EFFECTS IN BEAGLES

R.D. LLOYD, Univ. of Utah, School of Medicine, *Salt Lake City, Utah* 84112 (AT(11-1)-119)

Americium-241 is associated with 239Pu in reactor fuels and is becoming an increasingly important hazard in the nuclear industry. The retention, distribution, excretion, and effects of injected 241Am is being studied in beagles. A number of animals have been injected and their retained activity is being followed by total-body and partial-body counting. Soon after injection, about 50 percent and 40 percent, respectively, of the administered 241Am was deposited in the liver and in non-liver tissue (mainly skeleton). In the animals injected with 0.00179-0.305 mu Ci/kg, the liver and non-liver burdens decreased slowly each with a biological half-time of about 10 yr during the first 850 days. Two dogs injected with about 2.80 mu Ci/kg exhibited a sharp 'decrease' in liver retention beginning about 100 days after injection accompanied by an 'increase' in non-liver 241Am. Both showed extreme degenerative liver changes at death 401 and 448 days after injection. Excretion of injected 241Am was mainly urinary with about 7/8 of the total for the first 3 weeks appearing in the urine. Distribution studies of retained 241Am confirmed that liver and skeleton were the principal deposition sites, but showed activity in many soft tissues. Americium concentration in the thyroid gland was higher than any soft tissue except the liver. Autoradiography indicated that 241Am was deposited close to the functioning thyroid cells. The kidney also had a relatively high concentration of activity, selectively deposited in the glomeruli. Some surviving dogs injected with about 0.904 mu Ci/kg presently have functional damage to the kidney as well as the liver.

5.0723, RELATIVE BIOLOGICAL EFFECTIVENESS OF RADIONUCLIDES IN THE BEAGLE SKELETON

C.W. MAYS, Univ. of Utah, School of Medicine, *Salt Lake City, Utah* 84112 (AT(11-1)-119)

Osteosarcomas have been the chief cause of death in our adult beagles injected intravenously with bone-seeking radionuclides in citrate solution. The effectiveness of these nuclides depends on the type of radiation emitted and where this radiation is absorbed. Alpha radiation is more effective than beta radiation and the alpha emitters which deposit on bone surfaces are more effective than those which deposit throughout bone volume. For death with osteosarcoma 8 years after injection, values for relative biological effectiveness based on the average skeletal doses in rads one year before death and relative to 226Ra equals 1 are: 239Pu equals 6; 228Th equals 8; 228Ra equals 2.5; and 90Sr equals 0.07 to 0.24. Efforts are continuing to determine the relative effects of various radionuclides in producing other endpoints within a variety of induction times.

5.0724, DISTRIBUTION OF PB-210 IN CANINE BLOOD AFTER INTRAVENOUS INJECTION & ASSOCIATION OF NUCLIDE WITH BLOOD CONSTITUENTS IN DOGS & HUMANS (ABBRE

W. STEVENS, Univ. of Utah, School of Medicine, *Salt Lake City, Utah* 84112 (AT(11-1)-119)

After intravenous injection of Pb210 into beagles, the nuclide reached its maximum concentration in blood several hours after administration. Most of the Pb210 was associated with blood cells. The concentration in blood was measured for 287 days after injection at which time 0.058 percent of the injection dose was still circulating. 'In vitro' experiments with canine and human blood showed that about 90 percent of the nuclide combined with red cells was associated with the red cell cytoplasm and less than 10 percent was bound to the stroma. Transfer across the red cell membrane was possible without prior binding of the nuclide to plasma proteins. After gel chromatography and disc electrophoresis, most of the lead was found in hemoglobin containing fractions. In the dog varying amounts were also found in fractions of high electrophoretic mobility. In humans the largest fraction of Pb210 was found with a minor hemoglobin band. Only after saturation of this fraction greater quantities were found in the main hemoglobin band.

5.0725, DEATH FROM AGING, CANCER, IRRADIATION, AND OTHER STRESSES

B.J. STOVER, Univ. of Utah, School of Medicine, *Salt Lake City, Utah* 84112 (AT(11-1)-119)

Evidence is accruing that somatic mutations are important in aging and in the induction of the degenerative diseases as well as in oncogenesis and radiation damage (H.J. Curtis, Radiation and Aging, Symp. Soc. Exp. Biol., '21': 51-64, 1967). The occurrence of a mutation reflects a change in the environment of a cell which may be an alteration in the concentration of a critical precursor to the gene. Since biological processes proceed near equilibrium, the occurrence of such a change results in counter changes. Thus the mutation rate is a steady-state phenomenon. Application of the theory of absolute reaction rates makes it possible to analyze the life-shortening and oncogenic action of irradiation. Death curves for nonirradiated beagles that die from aging and cancer and those for beagles that receive skeletal alpha irradiation leading to osteogenic sarcomata are similar in shape. They differ in that death occurs earlier in the case of the irradiated dogs, and the hastening of death is a function of the radiation dose.

5.0726, MICROSCOPIC DISTRIBUTION OF 241-AM IN THE BEAGLE

G.N. TAYLOR, Univ. of Utah, School of Medicine, *Salt Lake City, Utah* 84112 (AT(11-1)-119)

Americium-241 retention in the soft tissues of the beagle following a single intravenous injection of a citrate buffered solution was significantly elevated in the following sites: In the hepatic cells of the liver, in macrophages containing engulfed hemosiderin, in calcified foci, such as those occasionally found in the renal medulla and in certain PAS positive connective tissue structures. The latter accounted for relatively high concentrations in the interfollicular areas of the thyroid, the renal corpuscles, the media of the smaller arterioles, and the cartilaginous structures of the lungs. Death resultant to kidney and liver failure occurred at approximately 400 days following injection of 2.8 mu Ci 241Am/kg.

5.0727, RADIUM INDUCED EYE TUMORS
G.N. TAYLOR, Univ. of Utah, School of Medicine, *Salt Lake City, Utah* 84112 (AT(11-1)-119)

Prolonged retention of 226Ra, 228Ra or 228Th has resulted in a significant number of intra-ocular melanomas in beagles. Thus far, such tumors have occurred below the lowest presently observed osteosarcoma dose by factors of 3 and 6 for 226Ra and 228Ra, respectively. They have developed at the lowest osteosarcoma dose in 228Th dogs, but not below this level. Intraocular melanosn was induced by 90Sr and 239Pu, but thus far, intraocular neoplasms have not been produced by these radionuclides.

5.0732, THE NATURE, INDUCTION AND REPAIR OF RADIATION-INDUCED C :NETIC DAMAGE IN PLANTS
R.A. NILAN, Washington State University, School of Agriculture, *Pullman, Washington* 99163 (AT(45-1)-2221)

This investigation is designed to obtain new knowledge about the nature of radiation-induced genetic damage, especially at the DNA level, and about the mechanisms by which ionizing radiations induce genetic changes in flowering plants. The specific objectives of the research are: 1) To determine the interrelationship among DNA lesion, mutations and chromosome aberrations in irradiated plant cells. 2) To determine how peroxides, catalase, peroxidase and gibberellic acid (which appear to be implicated in the radiation-induced damage in plant cells) affect the changes on DNA and, hence, chromosome aberrations and mutations. Seeds of Himalaya barley (CI 620) will be used in this investigation. DNA from treated and control embryos will be analyzed for breaks. These breaks will be compared to frequencies of chromosome aberrations and chlorophyll-deficient mutations within the same treated populations. The respiration inhibitor sodium azide will be utilized extensively in experiments under Obj. 1 since it differentially influences the ratio of chromosome aberrations and mutations in irradiated cells and since it induces mutations but no chromosome aberrations in non-irradiated cells. The manner by which sodium azide and gibberellic acid influence catalase and peroxidase levels in the cell and presumably the production of peroxides and genetic damage in irradiated cells will be determined by experiments for Obj. 2.

Results: Techniques for isolating, purifying and analyzing DNA from irradiated and control embryos of barley have been developed. The respiration inhibitor, sodium azide, in conjunction with radiation and at low pH increases chromosome aberrations but has no effect on mutation frequencies. On the other hand, when sodium azide is applied alone it induces a relatively high frequency of mutations but no chromosome aberrations. Sine the work on this projct has been recently initiated, results from experiments with gibberellic acid are too premature to report at this time.

5.0733, A STUDY OF FACTORS GOVERNING PLANT RADIOSENSITIVITY
R.A. NILAN, Washington State University, Agricultural Experiment Sta., *Pullman, Washington* 99163 (WNP01068)

OBJECTIVE: Detect and understand mechanisms through which ionizing radiation induced biological effects in cells of higher plants. Identify and determine the nature of the after-effects and indirect effects of ionizing radiation in seeds. Determine the action of agents and factors, such as oxygen and certain chemical mutagens, which modify the biological effects of ionizing radiation.

APPROACH: The actions of two mutagenic agents, namely oxygen and diethyl sulfate, which interact with radiation in the induction of biological effects in cells of irradiated barley seeds are being studied. These studies include experiments designed to help understand how factors such as water content and temperature of a seed and radiation energy influence the oxygen-radiation interaction and learn more about the nature of the factors which affect the mutagenicity of oxygen. Other experiments are probing the radiation-diethyl sulfate interaction with particular attention to the roles of hydrolysis products and pH and the induction of cytogenetic changes induced by the combined treatments and by X or gamma rays alone.

PROGRESS: Two of the components of damage in irradiated dry barley seed were analyzed. The oxygen-dependent, radical-dependent component can be modified by radiation energy between 300 kv and 50 kv and can occur at oxygen concentration as low as 3% O(2) in the hydration gas. This component is initiated by oxygen-radical interactions. The oxygen- independent, radical-independent component occurs in seeds not only at 10% and 12% water content but also at 6% water content. This component is not intimately involved with metabolism. More has been learned about the induction, prevention and repair of radiation-induced damage in plant cells. Gibberellic acid is a factor in these mechanisms and its breakdown and protection in irradiated cells have been determined. The respiration inhibitor sodium azide in conjunction with pH differentially modifies the ratio of mutations and chromosome aberrations in irradiated and non-irradiated cells. Studies of the induction and repair of genetic damage in terms of DNA lesions were conducted. DNA from barley embryos can be readily isolated and analyzed for radiation damage and repair.

5.0735, SPACE NUCLEAR SYSTEMS STUDIES
J.E. BALLOU, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

Space vehicles containing nuclear reactors or radionuclide power sources could present special hazards in case of early abort or upon return from orbit; the problems are principally those of small, intensely radioactive, insoluble particles. Studies are made of the deposition and retention kinetics of inhaled particles, determination of dose-effect relationships for individual or crushed particles passing through or retained in various regions of the gastrointestinal tract and lung, and with similar dose-effect conditions on the skin. Dogs and miniature swine have been the principal experimental animals.

Results: Some 30 dogs with various forms of 238 PuO2 deposited in thair lungs are being held for observation of late effects. One animal has developed an alveolar cell carcinoma, about 2 years postexposure, with a terminal body burden of 0.8 mu Ci. Three beagle dogs were exposed to aerosols of 238PuO2 - ZrO2 solid solution, and three to 238PuO2-ThO2 solid solution aerosols, and were euthanized 3 months postexposure to compare plutonium retention and translocation. No unusual effects were noted.

5.0736, FATE AND EFFECTS OF RADIONUCLIDES IN ALASKA
L.L. EBERHARDT, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

The objectives of this study are to determine the fate and effects of fallout radionuclides in Northern Alaskan environments. In the past, emphasis was placed on investigating the routes, rates, and amounts of SR90 and Cs137 in the lichen-herbivore-Eskimo (carnivore) food web. A study of the possible effects of chronic ingestion of radionuclides by man is implicit. An important aspect of this project is to quantify any potential radiation-induced effects, utilizing the most sophisticated techniques available; examination of chromosomal aberrations appears to be the most significant method.

Redults: The two-year study of seasonal cycles of Cs137 in three Alaskan population groups having different caribou utilization patterns was completed. Whole-body counting was continued at Anaktuvuk Pass on a semi-annual schedule to document summer maxima and winter minima. Extensive samples of caribou and carnivores were obtained as an aid in interpreting measurement of Cs137 in humans. A definite seasonal cycling of Cs137 in lichens became apparent, the 1969 spring caribou migration at Anaktuvuk Pass yielded animals that contained consistently greater Cs137 concentrations than had been expected - and ring and dicentric chromosomal aberrations were found in circulating leukocytes. No major differences were found in Cs137 concentrations in lichen samples obtained at Anaktuvuk Pass and at three sampling locations in the major caribou wintering ranges on the south side of the Brooks Range some 200 to 300 Km southwest of Anaktuvuk Pass. The unusually high Cs137 concentrations in caribou muscle resulted in higher maxima in Eskimo residents of Anaktuvuk Pass than had been expected; average values in adults were about twice those observed in July 1968. Two series of blood samples from male Anaktuvuk Pass Eskimos were analyzed for chromosomal aberrations as part of a cooperative study with Oak Ridge National Laboratory.

5.0737, URANIUM MINERS EXFOLIATIVE PATHOLOGY
M.E. FRAZIER, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

The purpose of this project is to compare the histopathology and pulmonary exfoliative cytology of experimental beagle dogs following inhalation of potential/pulmonary carcinogens to the cytology and pathology of uranium miners that have detectable pulmonary epithelial metaplasia or neoplasia. The experimental dogs have been exposed to low levels of inhaled 239PuO2, or to radon gas, cigarette smoke, uranium ore dust, diesel fumes, or combinations of these agents. Histopathology of lung tumors from uranium miners will be compared to those from hard rock miners which may give an indication of different pathogenic mechanisms. The work will establish culture systems for pulmonary neoplasms from uranium miners and experimental dogs.

Results: The cooperative review program has strengthened our capability to evaluate lung lesions in dogs, and has helped to standardize the nomenclature with accepted terminology of human lung lesions. Adaptation of special techniques, incuding special histochemistry and exfoliative cytology, has allowed a much better comparison of lung tumor pathogenesis and histology of induced tumors in dogs with those occurring in uranium miners.

5.0738, RADIATION EFFECTS ON CHYLOMICRON SYNTHESIS AND CAPILLARY PERMEABILITY IN MICE
J.C. HAMPTON, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

Ingested fatty acids cross the intestinal epithelium to enter the lymph and blood stream, even after X-ray doses which are known to strip epithelial cells of ribosomes and to appreciably alter other cell organelles responsible for protein synthesis. This must be reconciled with the fact that protein synthesis is required in the production of chylomicrons, the normal transport form of lipids. Are fatty acids present in plasma after irradiation incorporated into chylomicrons, or do they cross the damaged epithelium, unchanged, by diffusion? Radiation has been shown to affect capillary permeability in the small bowel of the mouse. Experiments will be performed to determine whether similar effects can be detected in other major vascular beds, primarily those of heart, lungs, kidney, pancreas and skeletal muscle.

Results: Copious amounts of labeled lipid were absorbed by jejunal epithelial cells, and a lesser amount by ileal cells, in controls, and at 1 and 2 days following 3 kR to total body X-rays. The amount of lipid in epithelial cells diminished rapidly at 3 and 4 days postirradiation. These cells seem capable of absorbing lipid but transport across the cells is greatly impaired. The fenestrated type of capillary normally present in intestinal villi promptly disappears as epithelial damage becomes more severe at the 3 and 4 day postirradiation interval.

5.0739, RADIATION PHYSICS
A.J. HAVERFIELD, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1))

This study is primarily concerned with how radiation produces effects in matter, particularly biological effects. This is done by studying the initial interactions by which ionizing radiations transfer energy to matter and the subsequent transport and degradation of that energy. The study includes determination of the partition and distribution of the energy in the radiation field and in the irradiated medium and the determination of rates and mechanisms of energy transferred and transported. Measurements were made of the differential cross section for ejection of electrons by fast proton impact on gas targets. Cross sections, differential in electron emission angle and energy, were obtained for N2 at nine angles between 20 degrees and 130 degrees, and for five proton energies between 300 keV and 1.7 MeV. The cross sections, integrated over the emission angles, were compared to those calculated from binary encounter theory. Good agreement is found except for electrons ejected with velocities approximately equal to the incident proton velocity. For such electrons, the calculated cross sections are about 1/2 the measured values. Similar results were obtained for electrons ejected from neon by 1.4 MeV protons and also for 1.0 MeV protons on molecular hydrogen. Study was made of the luminescence from benzene at room temperature upon excitation by electrons and protons. In

addition to the singlet monomer fluorescence previously unobserved under electron and proton bombardment in liquid benzene, several fluorescing radiolysis products were observed. By using a flowing liquid target, most of the radiolysis-product emission was eliminated and spectra consistent with those reported for u.v. excitation were obtained. The results suggest that the primary emission from benzene is the same for the various modes of excitation (electron and photon and proton irradiation).

5.0741, RADIATION AND HUMAN SPERMATOGENESIS

C.C. JANNKE, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

This program of cooperative research with Dr. C.A. Paulsen of the University of Washington, School of Medicine, was initiated in 1966. It has included counts, motility, vital staining, fluorescent antibody, and morphology studies of sperm in samples of seminal fluid collected from control and testicular irradiated subjects. These studies were designed to complement and augment the prime research program of Dr. Paulsen. Our participation in this program is limited to performance of tests on samples submitted by other participants. Results to date: The program included four volunteers receiving 100R of testicular X-irradiation, four receiving unilateral testicular biopsy, and two controls. Anti-human sperm antisera was produced in rabbits for positive controls. Sperm from controls was incubated with serum samples from irradiated and biopsied subjects and stained, by an anti-human gamma globulin fluorescent conjugate, for detection of human anti-sperm antibodies in test subject sera. Other monitoring tests included total sperm count, sperm motility rating, and percentage of live sperm. The group receiving 100 R X-irradiation showed an initial decrease in total sperm count within one week post irradiation. Sperm counts reached less than 10% of preexposure level by nine weeks postexposure and had not exceeded 10% by 59 weeks postexposure. Positive fluorescent antibody staining of sperm was demonstrable between 3 and 39 weeks postexposure. The total sperm count of the biopsied individuals decreased to less than 40% of the preexperimental values within 9 weeks posttreatment and had increased by 19 weeks posttreatment to greater than 50%. Postive fluorescent antibody staining was demonstrable between 5 and 27 weeks posttreatment.

SUPPORTED BY U.S. Atomic Energy Commission

5.0742, RATES OF DEPOSITION OF AIRBORNE RADIONUCLIDES IN THE ALASKAN ENVIRONMENT

C.E. JENKINS, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

The atmospheric deposition rates, routes, biological uptake rates, and concentrations of fallout radionuclides and their stable element counterparts in the terrestrial and marine environments of Alaska are being investigated. Emphasis is placed on food chains that consistently lead to higher radionuclide concentrations than found in temperate regions of the world and on the routes taken by radionuclides in their relationships to man and his environment. Included are stable elements, Be-7, Na-22, Pb-210, Po-210, and Ra-226, and the artificial radionuclides, including the major fission products and the neutron activation products. From knowledge gained, it is possible to relate air concentrations to concentrations in biota of terrestrial and marine environments, define the biological pathways and buildup of 15 to 30 radionuclides deposited from the earth's atmosphere, and establish the behavior and relationship of radionuclides to their stable element counterparts. It has been clearly demonstrated that radionuclides and their stable element counterparts do not necessarily behave alike in their initial uptake and retention by biological organisms. The study employs mainly neutron activation analysis for stable element measurements, while the radionuclide measurements are made primarily by direct instrumental techniques.

Results: Some 16 radionucides are being traced through a simple food web on three successive trophic levels, lichen-caribou-wolf or man. Each successive trophic food level discriminates against Mn-54, Co-60, Y-88, (Zr-Nb-95), Ru-103, Ru-106, Sb-125, Ce-144, Eu-155, Pb-210, and Bi-214, whereas Na-22, Zn-65, Ag-110m, and Cs-137 are concentrated on each level. Radium-226 is highly concentrated by caribou but not by wolf in the bone tissue. Radionuclide accumulations in lichen vary by species and the location; caribou and wolf accumulations are age, sex, and season dependent.

SUPPORTED BY U.S. Atomic Energy Commission

5.0743, EFFECTS OF IRRADIATING SKIN

D.D. MAHLUM, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

This project has three major objectives: (1) determination of the response of skin to ionizing radiation as influenced by size of exposure site and radiation dose administered, (2) determination of the effect of age at time of exposure, and (3) determination of the effect of combined treatment of the skin with radiation and known pharmacologic compounds with carcinogenic properties. Rats and miniature swine are used as test subjects.

Results: Observation continued on miniature swine exposed as young adults to Tl204 plaques of various areas. After 18 months, only the skin areas of 0.5 sq cm or larger, which were irradiated at the 6.25 krad or higher doses are grossly visible as thin, whitened circles. No signs of tumor development are apparent. Some tumors are beginning to appear in rats similarly exposed. At 15 months postexposure, tumors had developed at two of 192 sites exposed on adult rats, at 9 of 162 sites on rats exposed as weanlings, and at 28 of 165 sites on rats exposed shortly after birth.

5.0744, METABOLISM AND EFFECTS OF RADIONUCLIDES IN FETUS AND YOUNG

D.D. MAHLUM, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

Many of the biological parameters used to calculate permissible levels of exposure of adults to radioactive materials are inappropriate for the rapidly growing infant or child. These differences, together with the greater intrinsic radiosensitivity of the immature organism, emphasize the need for more detailed information on the metabolism and toxicity of radionuclides in the juvenile animal. This project has been principally concerned with the effects of age on the metabolism and toxicity in rats of I131, Cs137, Ce144, P32, Zn65, and the monomeric and polymeric forms of Pu238 and Pu239.

Results: The distribution of monomeric Pu239 was determined in the fetus and placenta of the rat, and the effects of such deposition noted at various intervals after injection of various times during gestation. From preliminary observation it appears that the incidence of mammary tumors in rats exposed to I131 while immature is elevated in comparison to unexposed controls of the same age or to animals exposed to the same radiation dose as adults. A variety of studies suggest that I131 beta irradiation of newborn rats is more effective than X-irradiation in decreasing thyroid function. Rats exposed to Ce144 as newborns, weanlings, or adults showed different patterns of carcinogenic response.

SUPPORTED BY U.S. Atomic Energy Commission

5.0745, TERRESTRIAL ANIMAL ECOLOGY

T.P. O'FARRELL, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

5. RADIATION

The terrestrial animal ecology project is to characterize the functional roles of the animal species of the Hanford ALE Reserve desert ecosystem. Special emphasis is placed on the relationships between population dynamics, physiological adaptations, and radiation sensitivity to environmental parameters, especially vegetative productivity, microclimatology, and the availability of water, minerals, and nutrients. Research efforts are also directed toward defining the fate and effects of elements in the desert-steppe and their transfer through the trophic levels.

Results: A population of free-ranging pocket mice, 'Perognathus parvus,' exposed to acute ionizing radiation in 1967 was sampled periodically to test whether there are synergistic effects between radiation insult and environmental stress; we have been unable to reject the null hypothesis of no interaction. Information on the long-term effects on the longevity and reproductive potential was summarized for three years. Longevity was inversely proportional to the amount of radiation administered. Trapping stations were established on the Reserve, with the objectives to determine distribution of species and relative abundance as a function of altitude and vegetation types, and to collect samples for a preliminary disease survey. Ectoparasites, including fleas, ticks, and lice, were preserved for each host, and tissue samples were preserved for histopathological diagnoses, serological testing, and examination for endoparasites. The higher elevations had the greatest species diversity, but the lower elevations had the greatest population sizes. Trapping also yielded information on the population dynamics of unirradiated small mammals. Apparently, the absence of seeds during years of poor germination of annual plants acts as part of a complex feed-back mechanism which effectively reduces reproductivity in the dominant mammals. Special emphasis was placed on describing the breeding biology of the grasshopper mouse, 'Onychomys leucogaster.'

5.0746, EFFECTS OF RADIOIODINE IN SHEEP AND SWINE

R.F. PALMER, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

Long-term radioiodine studies in sheep to define the lowest daily feeding level that will cause detectable damage during the lifespan of these animals have been in progress since 1949. The long-term feeding studies are completed, and only a few offspring animals, exposed in utero and by suckling, remain on observation.

Results: There were no unusual findings during the past year.

SUPPORTED BY U.S. Atomic Energy Commission

5.0747, INHALATION STUDIES - AEROSOL TECHNOLOGY STUDIES

J.F. PARK, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

The objective of this project is to develop techniques of aerosol generation, sampling and characterization applicable to animal inhalation exposure studies, emphasizing those aspects which enable more definitive analyses to be made of the extent to which the physical and physico-chemical properties of aerosols affect the deposition, retention, translocation, excretion and biological effects in animal as well as in a human exposure situation.

RESULTS: An examination of the characteristics of an aerosol as determined by several types of sampling instruments or combinations of instruments was initiated. A survey of techniques used for the generation of monodispersed aerosols led to the conclusion that the most promising methods for plutonium would be a spinning disk generator, for the size range 0.5 micro millimeters to 10 micromillmeters, using a plutonium dioxide or a plutonium nitrate colloid as feed material, and a vaporization-condensation technique for the size range 0.01 micromillometers to 0.5 micromillimeters using plutonium metal as the source material in an atmosphere of helium. The generation of constant concentrations of aerosols of various materials from dry powders was investigated in detail.

SUPPORTED BY U.S. Atomic Energy Commission

5.0748, INHALATION STUDIES - BIOLOGICAL EFFECT STUDIES

J.F. PARK, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

This project is concerned with the acute and chronic biological effects of inhaled radioactive particles to aid in defining critical tissues for permissible limit considerations. Pulmonary carcinogenesis is a major end point, investigated in dogs that have inhaled plutonium oxide particles. Effects in the lymphatic system are of particular interest, as are studies of the mechanisms of retention, clearance, and pathogenesis at the cellular level.

RESULTS: In a long-term study of the effects of inhaled 239PuO2, all 15 dogs that died after surviving as long as 54 months postexposure had lung tumors. The lowest plutonium lung burden associated with a tumor was 0.05 micromillimeters Ci at death, 9 years after exposure. Five animals survived in this study. Pathology data were obtained in continuing studies of the effects of inhaled 147Pm203, 239Pu and 238Pu, particularly in regard to the lymphatic system. Light and electron microscopic techniques were used to study the effects of inhaled 239Pu2 at the cellular level.

SUPPORTED BY U.S. Atomic Energy Commission

5.0749, INHALATION STUDIES - BIOCHEMICAL STUDIES

J.F. PARK, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

This project is concerned with the biochemistry of normal and irradiated pulmonary tissue. The objective is to aid in understanding the effects of inhaled radioactive particles. Most of the studies employ rats as the experimental animal.

RESULTS TO DATE: Lung lipid content increases 24 hours after exposure to X-irradiation. Lung mitochondria derived from thoracic X- irradiated rats incorporated more 14C from palmitate into lecithin, triglycerides, monoglycerides and diglycerides, between 14 and 24 hours postexposure, than did mitochondria derived from control animals. The microsomal fraction did not show this stimulation. In experiments designed to elucidate the pathway of lung lecithin synthesis, lung mitochondria, lung microsomes and slices of lung tissue were incubated with (Me - 14C) choline, 1, 2 - 14C choline, (Me - 14C) methionine, and (U - 14C) ethanolamine. The optimal conditions for incorporation by the subcellular fraction were determined. Palmitate is incorporated into lecithin almost exclusively as a whole molecule without prior elongation or modification.

SUPPORTED BY U.S. Atomic Energy Commission

5.0750, LOW LEVEL PLUTONIUM INHALATION STUDIES IN BEAGLES

J.F. PARK, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

This project is concerned with a specific experiment to determine the long-term effects in beagle dogs of low-level inhalation exposure to plutonium dioxide. The experiment will extend previous and continuing studies at higher exposure levels. It will test 238PuO2 as well as 239PuO2. Exposure levels will extend to as low as 0.002 muCi deposited in the lung, which corresponds to present permissible occupational deposition levels.

RESULTS: Breeding of dogs for this experiment is underway. Exposure chambers were designed and are being fabricated. A computerized data storage and retrieval system was developed for particular application to this experiment.

SUPPORTED BY U.S. Atomic Energy Commission

5.0751, COMPARATIVE DISPOSITION OF PLUTONIUM AND AMERICIUM AFTER INHALATION

J.F. PARK, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

Plutonium levels in exposed persons are often estimated by whole- body counting of Am241, which is present as a contaminant of all plutonium, and is more easily counted than is plutonium. This procedure is valid only if americium and plutonium are handled in a similar manner in the body. This project is testing that assumption by careful analysis of Am/Pu ratios in a variety of samples from dogs exposed to various types of plutonium at a variety of intervals prior to the taking of the sample.

Results: There is little indication that 241 Am and 239 Pu are significantly separated in the body after inhalation of 239PuF4 or 239PuO2 containing 241 Am.

5.0752, TERRESTRIAL PLANT ECOLOGY
W.H. RICKARD, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

The terrestrial plant ecology project deals with the intra- and inter-specific relationships of plants and the impact of physical and biological environment on plant distribution, growth, reproduction, and yield. It is also concerned with the movement and accumulation of mineral elements and radionuclides by plants and the relationship to the soil substrate. Detailed information on the functional roles of the flora are a requisite for interpreting and predicting the fate and effects of radionuclides in the environment. The area used in this project is the Arid Lands Ecology Reserve (ALE), a 120 square mile piece of the USAEC Hanford Reservation, located in the most arid part of Southeastern Washington State.

Results: Descriptive field studies range from community structure, phytosociology, and mapping to phenology and observations on the recolonization of cultivated fields. Quantitative studies measure the harvest yield, moisture use, and mineral and radionuclide uptake by the various kinds of plant communities. Laboratory studies measure the influence of moisture and temperature regimes and competition on the uptake of minerals and radionuclides by desert-steppe plants.

5.0753, REMOVAL OF INTERNAL EMITTERS
V.H. SMITH, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

The objective of this project is to develop methods that will hasten the removal, prevent the deposition, or otherwise decrease the damage potential from ingested or absorbed radionuclides. Necessarily associated with this effort is the development of information on the absorption, translocation, mobilization, and tissue distribution of radionuclides, to help in understanding and predicting their behavior and to serve as a basis for recommendations for the treatment of exposed persons. Rats or miniature swine are the usual test subjects and most agents are chelons or materials thought capable of mobilizing metals.

RESULTS: The deposition, total-body retention, excretion and blood disappearance of promethium were studied in miniature swine to complement earlier therapy experiments and to correlate with experiments in man. An effort to increase the efficacy or oral chelation therapy using aspirin as an irritant to increase the absorption of DTPA from the stomach was relatively ineffective. It was shown that Zn-DTPA was less toxic and a desirable alternate to therapy with the currently used Ca salt. As much as 140 mmol/kg of Zn-DTPA given subcutaneously at the rate of 2 or 4 mmol/kg per day had little effect on growth or rats when injections were started on day 4 or 10 after birth. The calcium and manganese salts were less well-tolerated. In weanling and newborn rats DTPA was more effective in preventing deposition when given 1 hour after plutonium citrate than similar treatment in adult rats; however, more plutonium was retained in the livers of the neonatal animals.

5.0754, INHALATION HAZARDS TO URANIUM MINERS, BIOLOGICAL STUDIES
B.O. STUART, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

The relatively high incidence of lung cancer and other pulmonary diseases in uranium miners is clearly associated with exposure to mine atmospheres. In addition to the hazard of inhaled radon daughters, ore dust concentrations, diesel engine exhaust fumes and cigarette smoking are possibly synergistic factors which must be considered. This project involves daily exposure of both hamsters and dogs to controlled levels of radon daughters and uranium ore dust for the lifespan of the animals. Four groups of 100 hamsters each receive daily exposures at 30, 600, and 600 WL plus ore dust, and controls. Eighteen dogs are being exposed daily to 600 WL plus ore dust; nine dogs are being maintained as controls. In parallel studies supported by the National Institute for Environmental Health Sciences, HEW, additional hamsters are being exposed to combinations of atmospheric contaminants including diesel exhaust fumes, and dogs are inhaling cigarette smoke in addition to the radon and daughters and ore dust.

Results: At nearly 1-1/2 years of age, the exposed hamsters are approaching their mean lifespan; 40-50% of the animals remain alive in each of the study groups. None of the animals examined to date showed pulmonary neoplasia. Final interpretations will be based upon detailed histopathological examination of all animals at the conclusion of the studies. No significant changes in respiratory rate, minute volume, tidal volume, thoracic radiographs, hematology or clinical chemistry have been observed in the dogs after six months exposure.

5.0755, GASTROINTESTINAL IRRADIATION STUDIES
B.W. WACHHOLZ, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

This project includes studies of morphologic damage, functional disturbances, permeability changes, and the influence of secretions as results of irradiation of the alimentary tract. The principal experimental animal has been the rat but more recently studies have been extended to miniature swine, rabbits, mice, and guinea pigs.

RESULTS: Additional data were obtained on the bilateral exposure of mature miniature swine to gamma radiation from a cobalt-60 source. The ratio of the median radiation dose for lower-body deaths to that which caused death after whole-body exposure was about 8 to 1, in contrast to the usual ratio of 2 or 3 to 1 seen for small laboratory animals. From the standpoint of both morphologic and histologic observations, vascular injury appeared to be more prominent in the irradiated intestine of swine than in that of rodents.

5.0756, U.S. TRANSURANIUM REGISTRY OF AEC, AEC CONTRACTOR AND LICENSEE EMPLOYEES
P.A. FUQUA, Hanford Environ. Health Found., *Richland, Washington* 99352 (AT(45-1)-1837)

To serve as a national focal point for the acquisition and provision of information about the effects of transuranic elements on man.

Investigations with laboratory animals have demonstrated that minute quantities of plutonium, americium, and other transuranium elements can cause malignant growth in the tissue in which it is deposited. The Registry will establish the applicability to man of these investigations through a program of data accumulation from details of exposures and autopsy findings of workers who have had exposures to the radionuclides of interest.

There is no accurate method for estimating low level depositions of commonly encountered compounds except by measurement of autopsy material. Development of standardized methodology for identification, selection and analysis of organ tissues represents a basic need and goal.

These objectives will be accomplished by establishing (a) a population of those workers past, present, and future who work with transuranium elements, (b) accumulating on a continuing basis, estimates of the amount and location of internal depositions of plutonium in these workers, and improving these determinations by reconciling with actual burdens found at autopsy or alternate means, and, (c) following such workers by clinical and epidemiological methods to determine adverse effects on health and longevity.

Results: Arrangements have been made at Hanford for inclusion in the Registry of all new workers who have become potentially exposed to the transuranium elements. Over 500 current employees at Hanford have been interviewed and have signed documents of cooperation.

SUPPORTED BY U.S. Atomic Energy Commission

5.0757, CHRONIC RADIATION EXPOSURE - CORRELATION OF RADIATION EXPOSURE WITH BIOLOGICAL EFFECTS ON MAN
P.A. FUQUA, Hanford Environ. Health Found., *Richland, Washington* 99352 (AT(45-1)-1837)

To determine the long range effects of low level chronic radiation exposure to man, including the incidence of leukemia or cancer, and the effect of the mortality rate and differential causes of death between those with occupational exposure to ionizing radiation and those not exposed.

Although certain biological effects of radiation have been noted in man, radiation induced shortening of life span comparable to that observed in animals has not been documented in human populations.

The research design utilizes multiple control groups of atomic industry workers. The mortality experience of each control group will be compared with the mortality experience of the exposed groups according to their ionizing radiation received in the course of their employment.

Results: Efforts to date have been directed to the accumulation of basic data on approximately 75,000 workers and siblings. Accumulation of radiation exposure data for twenty years has been completed for certain groupings of employees.

5.0759, LOW LEVEL CHRONIC IRRADIATION OF SALMON
L.R. DONALDSON, Univ. of Washington, School of Fisheries, *Seattle, Washington* 98105 (AT(45-1)-2225-T2)

Chinook salmon (Oncorhynchus tshawytscha) eggs and alevins were exposed continuously to low levels of gamma radiation from a 60Co source, from the instant of fertilization until the yolk sac was completely absorbed. The irradiated fish were compared with a similar stock that was not exposed to irradiation. The level of irradiation exposure was gradually increased from 0.5 roetgen/day for the 1960 brood year, to 1.3 roetgens/day in 1965, 2.8 roentgens/day in 1966, 5.0 roentgens/day in 1967 and to 10.0 roentgens/day, a total of 820 roentgens, for the 1968 brood year. In 1969 the level was increased to 20.0 roentgens/day.

RESULTS: At a level of 0.5 roentgen/day no damaging effects were found. The data for the higher levels of exposure will be evaluated as the adults return from the sea. Studies are carried on during the entire life span of the fish.

SUPPORTED BY U.S. Atomic Energy Commission

5.0760, EFFECT OF IONIZING RADIATION ON ISOLATED CELL NUCLEI
K.L. JACKSON, Univ. of Washington, School of Medicine, *Seattle, Washington* 98105

The objectives of this study are to define the mechanism of the damage caused by ionizing radiation to certain metabolic processes in lymphoid cells. It has been established that very shortly after exposure to X-radiation, lymphoid cells display an altered ability to take up nucleic acid and protein precursors and lose some types of materials to the surrounding medium. The present study is concerned with radiation-induced alterations in those processes which are responsible for transport of materials into and through the nucleotide pool.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0761, THE STUDY OF IRRADIATION EFFECTS ON THE HUMAN TESTIS - INCLUDING HISTOLOGIC, CHROMOSOMAL, AND HORMONAL ASPECTS
C.A. PAULSEN, Univ. of Washington, School of Medicine, *Seattle, Washington* 98105 (AT(45-1))

Our principal aims are: (1) to relate X-ray radiation dosage to changes in gonadal function, (2) to utilize the radiation gonadal changes as the means for studying anterior pituitary interrelationships, (3) to explore our current concepts concerning radiation dosage expressed in physical terms and their relation to biologic effects. Program aspects include quantitation of spermatogenesis, study of serum FSH, LH and testosterone levels following irradiation, studies of chromosomal changes and electron microscopy studies of testicular histology.

Results: The data accumulated so far indicate that the human testis is quite sensitive to X-ray irradiation. Thirty r delivered acutely produces brief azoospermia and 15 r produces severe oligospermia of a transient nature. Doses of 50, 100, and 400 r produce more rapid and extended periods of azoospermia. With increasing doses, recovery still occurs but is correspondingly prolonged.

SUPPORTED BY U.S. Atomic Energy Commission

5.0762, COLUMBIA RIVER STUDIES, 1970-1971
A.H. SEYMOUR, Univ. of Washington, School of Fisheries, *Seattle, Washington* 98105 (AT(45-1)2225,TA)

Two of the six proposed projects are temperature and ionizing radiation effect studies. For one project, larvae of the Pacific oyster will be exposed at various life stages to H3 and Zn65 and incubated at water temperatures ranging from 20 C to 28 C; for the other, phytoplankton will be exposed to temperature stresses up to 30 C above ambient in a manner that simulates the nuclear reactor. Radiation stress also will be applied. Another project is a long-term experiment to determine the biological half-life for zinc in oysters living in a natural environment. The relationship of the output of Zn65 by the Hanford reactors to Zn65 in marine organisms will be determined by monitoring Zn65 in mussels from the Washington Coast. The radiation dose to Willapa Bay oysters, in situ, and in sediments from a bay near the mouth of the Columbia River by means of thermo-luminescent dosimeters is the objective of another project. Lastly, the concentration factors and specific activity values for Cr51 in beach diatoms and Zn65 in Willapa Bay oysters will be determined from values for large water samples, hundreds of liters.

RESULTS: For oyster larvae, temperature effects occurred between 24 C and 28 C and at H3 and Zn65 concentrations of 10 to the minus 3rd power Ci/liter. For the alga, Chlamydomonas reinhardi, temperature effect on 14C uptake was observed at 45 C, 23 C above ambient. The biological half-life values for zinc in oysters varied with season and ranged from 100 to 1350 days, average 538 days. The decrease of Zn65 in Washington mussels taking into account lag time, is closely related to the shutdown of Hanford reactors. For a 1969 beach sample 62 miles north of the Columbia River the values for 51C and Cr were 271 pCi and 15.8 microgram per gram of dry sample.

SUPPORTED BY U.S. Atomic Energy Commission

5.0763, EFFECTS OF IRRADIATION, TEMPERATURE AND OTHER ENVIRONMENTAL FACTORS ON SALMONID EMBRYOS
A.D. WELANDER, Univ. of Washington, School of Fisheries, *Seattle, Washington* 98105 (AT(45-1))

The purpose of the research is to study the effects of ionizing radiation on the embryological stages of salmonids reared at different temperatures. Irradiation dose, which ranged from 12 to 1800 r (approx. 100 r/min.), in geometric progression, was delivered to seven different embryological stages. The fish were

irradiated and reared at temperatures ranging from 8.5 degrees C to 17.2 degrees C, and the effects on survival, growth, morphology and fecundity noted. These experiments indicate accelerated growth, not only by higher temperatures, but also by certain doses of ionizing radiation administered at critical developmental stages. Doses greater than 300 r appear to lower the tolerance to high temperatures and temperatures above 130 degrees C prove lethal for young chinook salmon independent of irradiation. Rainbow trout survive in water over 18 degrees C. More than 24,000 chinook salmon eggs have been used in this study, many of which were reared well beyond the feeding stages. In the spring of 1968, 469 rainbow trout eggs, irradiated with 21, 83, and 207 r at eyed stage were raised at comparatively high temperatures. These fish were spawned during the spring of 1970 with 65 females producing 176,000 eggs; 101,000 eggs have survived to the eyed stage. A limited number of these eggs, representing 8 experimental groups, will be held through the feeding stage for further observation.

5.0764, GENETIC EFFECTS OF CUMULATIVE IRRADIATION IN RATS
A.B. CHAPMAN, Univ. of Wisconsin, School of Agriculture, *Madison, Wisconsin* (AT)

The objectives of this research are to estimate the induced mutation rate in a mammal (albino rat) by sampling the genome broadly and, in conjunction with other data to provide a more realistic picture of the genetic effects of radiation in other animals and man. The traits used to reflect the effects on the genome are: sex ratio, size of litter, regularity of litter production, mortality rate of individuals at different stages of development, growth, age at sexual maturity, behavior, physical abnormalities, and kind and color of hair. Modifications of the lethal equivalent theory, and classical genetic techniques are being used as the means for estimating the genetic effects of irradiation.

Results: Estimates of X-ray induced dominant lethal mutants per gamete, per roentgen based on numbers per litter born alive, on those alive at 21 and at 69 days, 1.4 plus or minus 0.6 (10 to minus the 4th power), 1.4 plus or minus 0.8 (10 to minus the 4th power) and 0.9 plus or minus 0.9 (10 to minus the 4th power), respectively. Comparable estimates for autosomal recessive lethals are 1.0 plus or minus 0.8 (10 to minus the 4th power), 1.2 plus or minus 1.1 (10 to minus the 4th power) and 1.6 plus or minus 1.3 (10 to minus the 4th power). For sex- linked recessive lethals based on these same traits the estimates are 1.6 plus or minus 1.4 (10 to minus the 4th power), 0.8 plus or minus 1.9 (10 to minus the 4th power) and 2.0 plus or minus 2.2 (10 to minus the 4th power) per X-chromosome per roentgen. Genetic effects of cumulative irradiation on age at sexual maturity in the female and on body weights of males and females are also indicated.

SUPPORTED BY U.S. Atomic Energy Commission

5.0765, STUDIES ON THE EFFECT OF X-RAYS ON DNA SYNTHESIS IN POLYTENE CHROMOSOMES
W. PLAUT, Univ. of Wisconsin, School of Letters, *Madison, Wisconsin* 53706 (AT(11-1))

The results of our studies up to the present time have shown that unscheduled synthesis of DNA can be stimulated by both X-rays and ultraviolet light in the polytene chromosomes of Drosophila melanogaster, that this synthesis can be distinguished from normal DNA synthesis by its spatial distribution, its occurrence when normal DNA synthesis does not take place, its insensitivity to DNA and RNA inhibitors and its susceptibility to certain protein inhibitors when normal synthesis is not affected. Ultraviolet light, besides duplicating X-ray effects, does not induce incorporation in the presence of caffeine, but does in BU-DNA, although the rate of DNA synthesis as well as that of RNA is reduced.

Future plans include a more detailed study of protein involvement in induced synthesis using additional inhibitors, an attempt to obtain more detailed information at the molecular level through molecular autoradiography of DNA extracted from salivary glands, and an investigation of the possible relationship between repair synthesis and recombination, using mutations affecting the latter. We will also continue observations of the temporal replication pattern in genetically modified material and with analogues.

SUPPORTED BY U.S. Atomic Energy Commission

5.0766, THE EFFECTS OF IRRADIATION ON ERYTHROCYTE CHIMERISM & IMMUNOLOGIC TOLERANCE IN CATTLE TWINS
W.H. STONE, Univ. of Wisconsin, School of Agriculture, *Madison, Wisconsin* (AT(11-1)-1210)

To study the effects of irradiation and other treatments on the state of chimerism and immunologic tolerance in cattle twins. Being a unique in vivo system of interaction between genetically distinct tissues, it is possible to investigate the mechanisms that control and influence the relative proportions of the mixed tissues. In addition, chimeric animals exhibit immunologic tolerance allowing for reciprocal transplantation without immunosuppressive drugs. The possibility that the genetically unique tissues in a chimeric twin exchange chromosomes and genes is being investigated. Two cases of somatic cell mating have already been found and viruses are being used to enhance the occurrence of somatic cell mating. Immunologic studies on bovine embryos and fetuses are being performed, with regard to formation of chimerism. Some of this work is done at the Virginia Polytechnic Institute. Project began in 1961 and will be continuing.

RESULTS: Fractionated doses of whole body irradiation markedly shifts the equilibrium proportions between the two hematopoietic tissues in chimeric twins. The mechanism of this effect is not understood. Furthermore, a chimeric twin may exhibit partial tolerance for skin grafts and complete tolerance for kidney grafts. A comparison of the chimeric condition based on erythrocyte antigens and on lymphocyte types (karyotypes) revealed marked differences as might be expected of a state of split tolerance. Attempts to artifically produce chimeras have thus far failed using transplantation of hematopoietic tissues. New immunogenetic parameters such as allotypes have been discovered.

SUPPORTED BY U.S. Atomic Energy Commission

5.0767, RADIATION EFFECT ON PROTEIN & NUCLEIC ACID METABOLISM
M.B. YATVIN, Univ. of Wisconsin, School of Medicine, *Madison, Wisconsin* 53706

The continuing aim of this project is to obtain information about the nature of radiation-caused injury and recovery mechanisms of tissues in varying physiological states. As proposed in the original grant request, nucleic acid studies will be emphasized because of their unique role in controlling cell function through the regulation of protein synthesis. It is hoped that the proposed researches will enable us to determine why ionizing radiation apparently affects gene transcription and/or translation differently, depending on the mode of gene activation (i.e. hormonal, dietary, regenerating liver). We intend to extend our current program to investigate the nature of the action of ionizing radiation on gene expression in systems under hormonal control. Furthermore, in an effort to elucidate the mechanism of radiation injury and recovery, experiments utilizing radiomimetic drugs either alone or in combination with radiation are planned. Ideally, information obtained by such studies could be applied in both ameliorating the undesirable effects of radiation injury and conversely in enhancing the damaging effect of ionizing radiation on malignant cells. It is envisioned that these studies will be of value in the clinical radiotherapy of malignant disease.

5.0768, PHOTOBIOLOGICAL STUDIES ON EARLY DEVELOPMENT
A.F. RIECK, Marquette University, School of Medicine, *Milwaukee, Wisconsin* 53233

Studies will be made to hopefully identify specific photoproducts produced with ultraviolet irradiation in the developing system of Echinarachnius parma. Since it has been shown that UV can transiently delay the protein synthesis necessary for the subsequent DNA synthesis and karyokinesis and

cytokinesis of a given cell cycle, specific attempts will be made to learn the degree of differential production of photoproducts relative to this. Attempts will be made to learn if the photolesion is in the DNA or some of the DNA-like RNA which could possibly also be photoreactivatable. In addition studies will be made to learn if the same phenomenon can be observed if sperm are exposed to UV before fertilization as well as when eggs are exposed post- fertilization.

Investigations will continue regarding the separation, if possible, of photoproducts involved in cell division delay as compared to photoproducts which would be lethal or cause substantial changes in the developmental sequence.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0769, RADIOBIOLOGY OF NORTHERN FOREST COMMUNITIES

T.D. RUDOLPH, U.S. Dept. of Agriculture, North Central Forest Exp. Sta., *Rhinelander, Wisconsin* 54501 (AT(49-7))

This research is to provide information required to predict and to define the impact of ionizing radiation on natural forest ecosystems and on individual components of these ecosystems. Seasonal as well as long- term exposures to gamma radiation will be included to increase knowledge of the radiobiology of organisms comprising northern forest communities. A 1440 acre forest containing typical but diversified northern forest communities near Rhinelander in northern Wisconsin is the study area. The first phase of the research involves simultaneous gamma irradiation from a 10,000 curies 137Cs source of three forest types (aspen, paper birch, and northern hardwoods) for one growing season in 1971. Pre- irradiation evaluation of the characteristics, composition, and description of the communities including trees, shrubs, herbs, microorganisms, small mammals as well as microclimates within the communities is underway. The pre-irradiation studies are designed to permit interpretation of responses within a dose rate gradient, during and following irradiation, in terms of species composition, density, growth, phenology, distribution and diversity, as well as in microenvironments and litter, seed and dry matter production. To provide parameter guidelines for and to complement the radiation research on whole forest communities research on ionizing radiation effects on individual plant, small mammal and microorganism species is simultaneously being carried out under laboratory and cultivated gamma field conditions.

RESULTS: Early results, primarily from gamma field and laboratory studies, show that seed sensitivity of 9 gymnosperm species to gamma radiation varied by a factor of more than 4, but was not related to differences in nuclear parameters previously reported for the same species. Seedlings of 7 of the nine species were 7 to 15 times more radiosensitive than seeds of the same populations. No relation was found between seed and seedling radiosensitivity. White spruce pollen tolerates up to 3 times as much radiation as seeds and more than 10 times as much as young seedlings. Results have been published in Radiation Botany 10 and in 'Induced Mutations in Plants', IAEA, 1969. Other manuscripts are now being processed or in preparation.

5.0770, STUDIES ON THE EFFECTS (BIOCHEMICAL, MORBIDITY AND MORTALITY) OF RADIOACTIVE CONSTITUENTS OF URANIUM ORE ON HEALTH OF WORKERS

M. KILIBARDA, Serbian Inst. Oc. & Rad. Hlth., *Belgrade, Yugoslavia*

The purpose of the project is to obtain data on the health hazards associated with mining and processing uranium ore. The collection of a cohort on whom base-line studies have been made, makes it possible and appropriate to conduct this chronic effects study. Groups of workers who have been exposed to known concentration of radioactive particles and who have been studied during the past six years will be followed for an additional four years.

Specific studies will focus: (1) carcinogenic effects of radioactive particles on the respiratory system of uranium miners, (2) proliferative metaplastic and anaplastic appearances of cellular elements in miners' sputum, (3) respiratory diseases, chronic bronchitis, lung emphysema and pneumoconiotic processes, (4) respiratory function using spirometric methods, eximetric methods, and studies by radioactive gases; (5) lung clearance after radon inhalation under influence of various factors, (e.g. climate, smoking); (6) changes in the hematopoietic system, changes in erythropoiesis and leucogenesis; (7) appearance of binuclear-multinuclear cells (lymphocytes) and appearance of chromosome aberration; (8) other morphologic and biochemical changes in various enzymatic systems (e.g. alkaline phosphatase, peroxidase change in DNA, RNA, changes in resistance of leucocytes); (9) changes in endocrinological system, especially in adrenals in exposure to radioactive particles.

5.0773, THE DETECTION AND ANALYSIS OF MUTAGENS

B.N. AMES, Univ. of California, Graduate School, *Berkeley, California* 94720 (AT(04-3)34,0156)

1. It is proposed to assemble a set of bacterial mutants to use for the specific detection and analysis of the different classes of mutagenic agents. I have two objectives in mind. One is to have a set of strains that can be used by government agencies, and other interested parties, to screen pesticides, herbicides, food additives, drugs, etc. as mutagens. Humans are constantly being exposed to a variety of compounds that have not been tested as mutagens. My second objective is to use these strains for investigating the mode of action of various mutagens and in particular for finding mutagens that made specific changes in the DNA.

2. The mutations that one observes after mutagenizing a cell are only a small fraction of the total number of DNA changes that are made. We are trying to estimate the unobserved mutations in several ways. These mutations consist of changes in a gene that do not destroy the ability of the corresponding protein to function. In addition we are trying to estimate the proportion of genes in bacteria which, when destroyed, are not noticed on the usual media on which the bacteria are growing at the time.

Results: A variety of bacterial tester strains have been developed, many of which are lacking the excision repair system, that are specific and extremely sensitive to various types of mutagens. A specific system has been developed for detecting deletion mutations.

A theory has been proposed that the ultraviolet component of sunlight is the evolutionary force that determines the DNA base ratios of bacteria.

5.0774, CHARACTERIZATION OF RADIOPROTECTIVE FACTOR IN ALFALFA

D.H. CALLOWAY, Univ. of California, Agricultural Experiment Sta., *Berkeley, California* 94720 (CA-B0-NTS-2267)

OBJECTIVE: Isolate and characterize the radioprotective factor from alfalfa, discover the mechanism by which increased

resistance to radiation injury is accomplished; and determine the importance of this mechanism in a variety of animal species. To aid in isolational studies, effort will be directed toward development of a more rapid assay requiring smaller amounts of material.

APPROACH: Isolation and identification work will continue during the next year. Spectral analysis and chemical tests for unsaturation and specific reactive groups will be made. A summary of these tests will be used to design a column chromatographic separation based upon chemical structure. However, the PHS grant has expired and is not being renewed, so biassay of fractions will be delayed until funds are available from a new source.

PROGRESS: Attempts to process alfalfa fraction beyond the steps of cold-water extraction and freeze-drying have resulted in substantial loss of radioprotective (RP) activity. Earlier studies have shown RP factor to be sensitive to oxygen, and it is probable that oxidation occurs after the factor is separated from the antioxidants naturally present in alfalfa. Antioxidants that have RP activity for rats, BHT and propylgallate, were added to guinea pig diet to determine if these could be used as processing additives during isolation of RP factor. In contrast to the rat, guinea pigs did not tolerate the substances well. Mortality was greater after irradiation with 0.5 percent BHT in the diet than with the bran-oats diet alone. Addition of alfalfa both diminished radiation sensitivity and offset the detrimental effect of BHT. Ash of whole alfalfa improves response to radiation but a mixture of Ca, Mg, Na, K, and Cl salts does not account for the entire effect. Ash prepared from the water-soluble RP fraction is not as effective as whole alfalfa ash. In irradiated animals, the effects of RP fraction and ash are additive, indicating that some mineral(s) is deficient or imbalanced in the basal diet and that RP factor is not an inorganic compound.

5.0775, BIOPHYSICAL EXPERIMENTS WITH POSITIVE AND NEGATIVE PIONS

S.B. CURTIS, Univ. of California, Lawrence Radiation Laboratory, *Berkeley, California* 94720 (W-7405-ENG-48)

Negative pions produced by high-energy protons over an energy of about 400 MeV have the property of penetrating into tissue with relatively low ionization density. After the particles come to rest, they interact with the nuclei of atoms and produce stars consisting of short-range protons, alpha particles, nuclear fragments, and neutrons. The highly ionizing short-range particles cause a large local dose deposition, thus enhancing the peak-to-plateau dose ratio of the usual Bragg curve. This project aims to evaluate by direct experimentation the physical properties of high-energy pion beams produced at the 184' cyclotron, especially the dose and LET distribution of the beam, and to study important radiobiological parameters, such as RBE and OER, with suitable biological test objects.

Results: The relative biological effectiveness (RBE) and the oxygen enhancement ration (OER) of pi negative mesons at the peak of the depth-dose distribution was measured for induction of arginine reversions in diploid yeast. The mutation-induction efficiencies for dose rates of 40 rad/hr and 40 rad/min of 60 Co-gamma rays are about the same. The OER for 60 Co-gamma rays was 2.4. For pi negative mesons at the peak of the depth-dose distribution, an RBE value of 1.5 and an OER of 1.8 were obtained.

SUPPORTED BY U.S. Atomic Energy Commission

5.0776, BIOPHYSICAL EXPERIMENTS WITH POSITIVE AND NEGATIVE PIONS

S.B. CURTIS, Univ. of California, Lawrence Radiation Laboratory, *Berkeley, California* 94720 (W-7405-ENG-48)

Negative pions produced by high-energy protons over an energy of about 400 MeV have the property of penetrating into tissue with relatively low ionization density. After the particles come to rest, they interact with the nuclei of atoms and produce stars consisting of short-range protons, alpha particles, nuclear fragments, and neutrons. The highly ionizing short-range particles cause a large local dose deposition, thus enhancing the peak-to-plateau dose ratio of the usual Bragg curve. This project aims to evaluate by direct experimentation the physical properties of high-energy pion beams produced at the 184' cyclotron, especially the dose and LET distribution of the beam, and to study important radiobiological parameters, such as RBE and OER, with suitable biological test objects.

Results: A method for 'in vitro' culturing of human blood lymphocytes was standardized. Radial responses to cobalt gamma radiation and negative pions were determined. The shape of the six-day survival curve with gamma dose indicated the existence of two population of lymphocytes with different radiation sensitivities. The survival of the sensitive fraction was exponential in nature and has a D sub zero value of about 80 rads. The value for the other insensitive population was around 270 rads.

5.0777, BIOPHYSICAL EXPERIMENTS WITH POSITIVE AND NEGATIVE PIONS

C. RICHMAN, Univ. of California, Lawrence Radiation Laboratory, *Berkeley, California* 94720 (W-7405-ENG-48)

Negative pions produced by high-energy protons over an energy of about 400 MeV have the property of penetrating into tissue with relatively low ionization density. After the particles come to rest, they interact with the nuclei of atoms and produce stars consisting of short-range protons, alpha particles, nuclear fragments, and neutrons. The highly ionizing short-range particles cause a large local dose deposition, thus enhancing the peak-to-plateau dose ratio of the usual Bragg curve. This project aims to evaluate by direct experimentation the physical properties of high-energy pion beams produced at the 184' cyclotron, especially the dose and LET distribution of the beam, and to study important radiobiological parameters, such as RBE and OER, with suitable biological test objects.

Results: A dose rate of 60 rad/hr was obtained by focussing the beam to a size of 2x4 cms. This beam is of sufficient intensity for biological experiments. Measurements of depth-dose distributions of negative pions indicate no significant variations. About 2 percent of stopping pions produce high energy gamma rays. By detecting these gamma rays using spark chambers, it is possible to map the stopping pion region.

5.0778, BIOMEDICAL RESEARCH USING HUMAN WHOLE-BODY COUNTER

T.W. SARGENT, Univ. of California, Lawrence Radiation Laboratory, *Berkeley, California* 94720 (W-7045-ENG-48)

Rapid diagnosis of accidental human radionuclide contamination with regard to identity and total body burden of the isotope, and study of the progress of treatment or natural loss rate in cases where a burden has been acquired. Routine whole-body counting of LRL employees with a potential of exposure to radionuclide contamination. Use of isotopic tracers in studies of metabolism in normal volunteers and in patients with various diseases, utilizing small amounts of tracer giving a minimal radiation dose to the patient. Development of computer programs to utilize the data from metabolism studies in compartmental analysis. Clinical application of iron absorption and blood loss tests using Fe59 has continued. The patient who was found to be heterozygous for Wilson's disease is being studied further. We found that zinc is incorporated into one of the molecules which also contains copper, and on the supposition that this molecule may be the one affected by the gene for this disease, the whole-body turnover of zinc is being studied in our heterozygous patient.

RESULTS: Eight patients with hemochromatosis were studied before, during, and after phlebotomy therapy. After completion of therapy, when the patient's serum iron and all other blood indices were normal, the absorption of oral iron was in all cases above normal. Patients on diuretic therapy are counted periodically to determine whether they are becoming potassium depleted, because serum potassium does not fall until intracellular potassium has been considerably depleted, whole-body K40 measurements have made it possible to detect depletion before serum potassium measurements all

5.0779, SCINTIGRAPHY USING THE SCINTILLATION CAMERA, POSITRON CAMERA, MARK II WHOLE BODY SCANNER AND MULTIPLANE TOMOGRAPHIC SCANNER (ABBREV)

D.C. VANDYKE, Univ. of California, Lawrence Radiation Laboratory, *Berkeley, California* 94720 (W-7405-ENG-48)

This project is concerned with application of new devices and improvement in the techniques for obtaining and quantitating scintigrams showing the 'in vivo' distribution of radioisotopes in the human body.

Part of the program includes development of supplemental techniques which increase the usefulness of such organ-imaging devices. These include the 80-lens sequence camera attachment for recording dynamic studies, a videotape system to record the data from the scintillation camera for subsequent quantitative analysis and reply, and area-of- interest shielding devices for sequential digital readout using either the scintillation camera or Mark II whole-body scanner.

A high priority aspect of this project is the constant search for methods of reducing the radiation dose to the patient without sacrificing quality of the information obtained. This can be accomplished by development of better isotopes, increased sensitivity of imaging devices and larger fields of view.

Areas of investigative interest include improvement of techniques for visualization and quantitation of the perfusion and ventilation of the lungs; improvement of techniques for hepatic, renal, and brain scintigraphy; and extension of studies of the distribution of erythropoietic bone marrow; and evaluation of regional blood flow to bone and bone marrow disorders.

Results: A scintillation camera with 16-inch crystal and 13-1/2 inch field of view has been perfected and is in clinical use. The tomographic scanner which shows the distribution of radioisotopes in the body in three-dimensional space has been evaluated. The Mark II whole- body scanner has proven to be an extemely valuable and versatile clinical diagnostic and research instrument.

5.0780, THE APPLICATION OF SOLID-STATE LITHIUM-DRIFTED GERMANIUM DETECTORS TO THE ANALYSIS OF RADIONUCLIDES IN BIOLOGICAL AND ENVIRONMENTAL SAMPLES

A.E. BRADLEY, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

Primary to the objective of decreasing the minimum detectable levels of radionuclides in biological and environmental materials will be the development of a solid-state lithium-drifted germanium detector array having an equivalent surface area of approximately 80 square centimeters and an active depth of one centimeter. System resolution, measured at the energy of Co-60, 1.33 MeV is expected to be less than 3.5 keV. Counting efficiency will be one of the main goals. Independent cryogenic chambers for each detector will be developed, with up to four detectors in the system. The initial signal conditioning will be done by field effect transistors to liquid nitrogen. Signal processing to maintain high resolution will be of prime consideration. Initial uses will be for detecting trace radionuclides in various biota and whole- body small animal counting. Future uses may include collaborative studies with other AEC laboratories and medical facilities for detection of human tumors.

Results: We have gained extensive insight into problems associated with small and medium size detectors as applied to biological and environmental counting. A small (28 square centimeters) four-detector array has been constructed. Resolution was 2.9 keV at 1.33 MeV. Whole- body counting of small animals showed the feasibility of analyzing complex mixtures of radionuclides in vivo.

SUPPORTED BY U.S. Atomic Energy Commission

5.0781, DETERMINATION OF UPTAKE RATES, ORGAN SPECIFICITIES, AND BIOLOGICAL LIFETIMES OF RADIOISOTOPES AND ELEMENTAL SPECIES IN THE RAT

D. FLESHMAN, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

These experiments are designed to evaluate the relative efficacy of several chemical countermeasures in reducing the absorption of ingested radionuclides from the gastrointestinal tract and/or increasing the excretion rate of those already deposited within various tissues. By reducing absorption or increasing the removal rate of radioactive materials, radiation exposure and the possible associated hazards are reduced. Data from these experiments may lead to prescribed treatment procedures for any radionuclide which may present a problem to man. Control and experimental groups of rats are stomach-fed a mixture of the radionuclides; treatment is begun on the experimental groups and whole- body counting is carried out on a lithium-drifted germanium diode at preestablished intervals during the experiment. A high-resolution gamma-ray spectrometer makes possible the quantitative and qualitative determination of complex, low-level mixtures of gamma-emitting radionuclides in small animals. Countermeasures to be evaluated include sodium alginate, penicillamine, diethylene-triaminepentaacetic acid 2,3-dimercaptoethanol, 2,3-dimercaptopropionic acid, and 2,3- dimercaptosuccinic acid. Studies are also carried out on the deposition and retention of selected radionuclides in the rat.

Results: Orally administered sodium alginate was shown to be effective in reducing the retention of several radionuclides in rats in the following descending order: Ba, Sr, Cs, Zn, Hg, Sn, Mn, Co. The Ba- 133 levels were reduced to 3 percent of control values and Cd-109, Hg- 203 levels to be about 50 percent. Co-60 levels were not affected.

Orally administered tantalum was found to be only slightly absorbed - less than 1 percent - the principal accumulation sites being bone and pelt.

SUPPORTED BY U.S. Atomic Energy Commission

5.0782, QUANTITATION OF LOW LEVELS OF TRITIUM IN BIOLOGICAL AND ENVIRONMENTAL MATERIAL

E. MORIMOTO, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

A number of the Bio-Medical Division's research projects require the quantitation of low levels of tritium in biological and environmental samples, particularly the studies of human organs and foodstuffs in the chain leading to man, and the radioecological studies on the fate of low levels of tritium liberated to biosphere at the sites of Plowshare gas-stimulation programs and at nuclear power reactors. Conventional liquid scintillation techniques are not sensitive enough for most of these biological and environmental samples; consequently, it is necessary to develop specialized systems.

Four specialized systems are being developed and assembled. The first is a system to enrich by electrolysis tritium content of samples. The second system will combust hydrogen in organic matter to water; the water so produced will be trapped cryogenically. The third converts water as water vapor to hydrogen for gas-counting. The last is a gas- counting system for counting tritium as hydrogen gas.

Results: Some preliminary work has been done on the development and assembly of the four specialized systems described.

SUPPORTED BY U.S. Atomic Energy Commission

5.0783, ANALYSIS OF RADIONUCLIDE PRODUCTION FOR PREDICTION OF UPTAKE AND DOSES FROM RELEASE OF RADIONUCLIDES

Y.C. NG, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

This analysis of radionuclide production is a main category of a predictive program designed to provide the following kinds of information: (1) guidance for radiation safety analysis of

proposed applications involving nuclear energy, (2) guidance for documentation of the release of radionuclides to the biosphere, and (3) guidance for design in applications involving nuclear energy. The objective of this phase is to predict the maximum quantity of any given radionuclide that could be produced and subsequently be released to the environment. Estimates of radionuclide production and radionuclide inventory as a function of time are evaluated in relation to their possible release to the biosphere and transfer to man by way of the food chain. Estimates are made of the internal dosage to man that could result from a variety of situations involving acute and continuous release. The overall approach is described in a series of reports. Radionuclide production and inventories in various applications, such as reactors and their waste storage facilities and fuel reprocessing plants, will be considered and integrated in the overall program.

Results: The application of this approach to the Plowshare cratering program revealed the relative importance of device activation to the bone and whole body dosages and the importance of fission by virtue of the estimated dosage to the child's thyroid from Iodine-131. It also revealed the potential biological gain that could be achieved by using separated isotopes for the fabrication of nuclear explosives for peaceful purposes.

5.0784, PREDICTION OF BIOLOGICAL FATE AND RADIATION DOSES FROM RADIONUCLIDES RELEASED TO THE BIOSPHERE

Y.C. NG, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

This analysis of the biological fate and radiation doses from radionuclides released to the biosphere is a main category of a predictive program designed to provide the following kinds of information: (1) guidance for radiation safety analysis of proposed applications involving nuclear energy, (2) guidance for documentation of the release of radionuclides to the biospheres, and (3) guidance for design in applications involving nuclear energy. This portion of the prediction effort is oriented toward prediction of the radiation dose to man from any release of radionuclides into his environment. Biological uptake relationships are combined with estimates of radionuclide production and transport into terrestrial and aquatic ecosystems to arrive at estimates of the burden and dosage to man. An important aspect of the predictive approach is the collection, storage, and recall of documents that provide either data on these parameters or useful collateral information. A revision of the Handbook for Estimating the Maximum Internal Dose from Radionuclides Released to the Biosphere, which is in progress, should improve the prediction of the dosages that could result from a single release of radionuclides from any source. It should also enhance the overall validity of estimates of the dose-rate and steady-state concentration of nuclides resulting from the continuous release of radionuclides to the biosphere. The program will also include the application of our predictive approach to specific ongoing or proposed nuclear projects.

Results: The overall approach is described in a series of reports. One of these reports is a continuously updated Handbook that lists the input parameters required for estimation of dose.

5.0785, SOMATIC EFFECTS OF LOW-DOSE RADIATION - CHROMOSOME ANALYSIS AND ANALYTICAL METHODOLOGY

S.P. STONE, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

Objective is to provide, through the acquisition and development of image processing devices and the development of associated computer programs, suitable systems for automated processing and analysis of large numbers of chromosome metaphase spreads. Measured parameters obtained are statistically evaluated for valid conclusions pertaining to qualitative and quantitative aspects of somatic effects of chronic low- dose irradiation of humans.

For three years, a film reader (8 gray levels) has been used to digitize data from photographs of idealized representations of spreads. Computer programs in pattern recognition, result merging and statistics were built and used to analyze such data. Presently under development is a facility using a small computer with, 1) a film reader (64 gray levels), 2) and image dissector system for projected microscope image scanning, and 3) display devices and computer peripherals attached. This facility may operate independently or as a terminal with a large time- shared computer through a direct data link. Pattern-recognition techniques are being extended to analyze data from this system with an emphasis on data from 35-mm photomicrographs of normal or near normal spreads.

Results: Our first system has been fully developed into a reliable and efficient tool which was successfully used in analyzing nearly 7000 idealized metaphase representations and in obtaining conclusions. Our new film reader has demonstrated superior capability. The new system is sufficiently complete that it has replaced the older one. Present efforts will continue in full development of this system, particularly in terminal-type operation.

5.0786, HIGH ALTITUDE RADIATION INSTRUMENT SYSTEM

H.S. KATZENSTEIN, Solid State Radiations Inc., *Los Angeles, California* 90064 (000577)

This program is for the development and manufacturing of 4 units of a High Altitude Radiation Instrument System (HARIS) which was fabricated by Radiation, Inc., Los Angeles, Calif. It will be used in the High Altitude Radiation Environment Study (HARES) to obtain measurements of ionizing radiation at SST cruising altitudes. The instruments meet the specifications of the 3 agencies participating in this program; namely, the FAA, NASA, and the USAF. The HARIS package will be installed in aircraft flying at various altitudes and latitudes.

Four HARIS units of the type specified above have been developed and are being flown in USAF and NASA aircraft. The instuments were calibrated with various radiation sources in order to obtain reliable measurements. The intruments were delivered to and accepted by personnel from the AF Weapons Laboratory at Kirtland AFB, N.M., who are the technical monitors of this project. Several units were calibrated using the Brookhaven National Laboratory medical research reactor, and gamma and neutron sources available at Kirtland. More than 60 flights were made from Kirtland AFB, Moffitt Field, Calif., and Eielson AFB, Alaska in which the HARIS was used. A computer program was developed at the AF Weapons Laboratory to analyze the data. Contract FS-65-24 to produce the 4 HARIS units was completed and the warranty has expired. The current contract covers maintenance and modification costs of the instruments during the data collection period.

No additional funding is presently planned or anticipated.

5.0787, PRECIPITATION, AIR TEMPERATURES, SOIL MOISTURE, & GAMMA RADIATION, IN 68 MOJAVE & GREAT BASIN ECOSYSTEMS, NEVADA TEST SITE, 1962-70 (ABBREV)

J.C. BEATLEY, Univ. of California, Lab. of Nucl. Med. Rad. Biol., *Los Angeles, California* 90024 (AT(04-1)GEN-12)

As minimal documentation of the seasonally fluctuating physical environmental variables of sites of biological studies, measurements have been made weekly or bi-weekly, from 1962 to the present, on the sites of 68 selected ecosystems in eight drainage basins of the Nevada Test Site. Variables measured are rainfall, maximum and minimum air temperatures at the 1-foot level, soil moisture and temperature at the 3-, 6-, and 10 inch levels, and gamma radiation. In addition to their use in understandings of the behavior and distributions of biological populations in this region of southern Nevada, the data-which are the most areally intensive and extensive and have the longest continuous record of any meteorological sampling program over this 100 square mile area-are expected to be of utility in Nevada hydrologic studies, and storm patterns, and other. The soil moisture record is a pioneer effort in desert ecosystem studies.

5. RADIATION

SUPPORTED BY U.S. Atomic Energy Commission

5.0788, THERMOLUNINESCENCE OF GAMMA- AND NEUTRON-IRRADIATED SOILS
H. NISHITA, Univ. of California, Lab. of Nucl. Med. Rad. Biol., *Los Angeles, California* 90024 (AT(04-1)GEN-12)

The objective of this study is to determine the characteristics of soil thermoluminescence, in order to determine whether or not soil can be used as a radiation dosimeter. At present,several kinds of manufactured thermoluminescent dosimeters are being used in gamma radiation fields established to study the effect of radiation on ecosystems. In such a radiation field, the dosimeters can be placed at the selected sites before exposure to radiation. The pre-irradiation placement, however, may not have been done always at the appropriate sites or in sufficient number to fully assess the radiation field. In areas exposed to an unexpected nuclear detonation, pre-irradiation placement of dosimeters certainly will not have been done. Under these circumstances it may be advantageous if the soil or other materials in the environment could be used to estimate the radiation exposure. Experiments are in progress using Cs137 and Co60 sources. Some experiments are also being conducted under conditions of actual nuclear detonation at Nevada Test Site.

Experiments in the laboratory have shown that a number of factors need to be considered in using soil as a dosimeter. Some of these factors are decay, spurious effects, heating rate, temperature during sample irradition, particle size distribution of the samples, mineral composition of the samples, etc.

5.0790, MEASUREMENTS OF NATURAL RADIOCARBON AND TRITIUM
H.E. SUESS, Univ. of California, Graduate School, *San Diego, California* 92038

The project is a continuation of NSF Grants GA-17689 and GA004481. The two previous grants are now combined into one. The objectives of this project are multi-disciplinary in character, involving determinations of carbon-14 in samples of known age for the purpose of establishing the radiocarbon time scale and determining dendrochronologically-calibrated radiocarbon ages. The various studies include: 1) Distribution of natural radiocarbon in bicarbonate of the deep oceans for the investigation of the movement of deep ocean water masses. 2) Distribution of artificial radiocarbon in the surface water of the Pacific Ocean for the purpose of investigating mixing through the thermocline. 3) Secular variations of the radiocarbon level in the atmosphere derived from measurements of carbon-14 in wood, dated from its tree rings, investigated as a geophysical parameter for the study of variations in the cosmic ray intensity and of changes in the terrestrial carbon distribution. 4) Measurements of carbon-14 in wood of known age for the purpose of establishing calibration data for the conversion of radiocarbon ages into true ages. Another aspect of the program is making measurements of tritium in ocean water and in precipitation. Emphasis will be placed on: 1) Measurements of interest in connection with the mixing rates of the oceans. 2) Measurements in connection with problems of general hydrology. 3) Measurements in connection with the problem of the pre-bomb natural tritium level and its variations.

SUPPORTED BY U.S. National Science Foundation

5.0791, REPAIR OF RADIATION-DAMAGED DNA IN HUMAN AND OTHER MAMMALIAN CELLS
J.E. CLEAVER, Univ. of California, Laboratory of Radiobiology, *San Francisco, California* 94122 (AT(11-1)-GEN)

The DNA of human cells which has been damaged by ultraviolet (UV) light is repaired by excision of the damaged regions and synthesis of a replacement region (excision repair). We will determine the size, genomal distribution, and integrity of the repaired regions in human cells and study the connection between the failure of excision repair in skin and subsequent actinic carcinogenesis in the human hereditary disease xeroderma pigmentosum. An animal model for this disease is being sought amongst inbred Hereford cattle which show a high incidence of actinic cancer of the eye. Excision repair is more complex in rodent than in human cells, but with repair in the latter serving as a heuristic model we will ascertain the biological importance of excision repair in rodent cells. We will then isolate mutant cell lines in culture which are analogues of xeroderma pigmentosum cells. Using these mutants we will perform somatic hybridization between excision repair deficient rodent cells and normal human cells to locate the excision repair genes on a particular human chromosome.

Results: We have found that excision repair of UV damage in human fibroblasts isolated from the skin occurs by the following enzymatic sequence: (1) an enzymatic break is made in UV-damaged DNA, (2) the UV damage is excised, and (3) a replacement region is synthesized. Cells from human patients with xeroderma pigmentosum are homozygous for a gene which causes a defect in step (1) of the excision repair system. This defect renders the cells three to ten times as sensitive as normal cells to killing by UV light.

5.0792, STUDIES OF ENDOGENOUS SULFHYDRYL GROUPS
J.W. HARRIS, Univ. of California, Laboratory of Radiobiology, *San Francisco, California* 94122 (AT(11-1)-GEN)

Our earlier observation that the reduced glutathione (GSH) content of mammalian cells varies according to their position in the cell cycle has been pursued with reference to the relationship between cellular GSH and cellular radiosensitivity. Present research is directed to three major questions: (1) Does GSH play a role in radiation injury and repair? (2) What specific functions does GSH serve in the economy of mammalian cells, e.g., with respect to macromolecular synthesis or mitosis? (3) Do protein sulfhydryl and disulfide groups contribute to cyclic radiosensitivity? These studies involve assay of GSH in synchronized cells and are facilitated by two reagents that are specific oxidants for low molecular weight thiols (e.g., GSH): methyl phenyldiazenecarboxylate and diazenedicarboxylic acid bis (N,N- dimethylamide). These reagents can completely and reversibly oxidize cellular GSH to the disulfide without affecting protein thiol groups, and they are being used to test the so-called 'mixed disulfide' hypothesis of chemical radioprotection. These studies are presently confined to cellular systems in vitro, but may be extended to in vivo systems.

Results: The bulk of endogenous cellular GSH does not play a prominent role in cellular radiosensitivity, at least at doses below 1000 R. Although GSH clearly protects enzyme SH groups against other oxidants (e.g., molecular oxygen), our results do not support a radioprotective role for endogenous GSH. There is some evidence that GSH may participate in repair of radiation damage, but this has not yet been firmly established.

5.0793, NEUTRON DOSE BELOW 500 KEV IN A CRITICALITY ACCIDENT (PART OF A COORDINATED PROGRAMME ON NUCLEAR ACCIDENT DOSIMETRY) (ABBREV)
W. CROSS, Atomic Energy of Canada Ltd., *Chalk River, Ontario, Canada*

In a criticality accident an important fraction of the neutron dose may be delivered by neutrons with energies between 30 and 500 keV. Because it is not feasible for individuals to wear dosimeters that measure the dose from these neutrons, this must be determined either from more comprehensive, installed monitors or estimated from measurements on neutrons of higher and lower energies, using some assumptions about the spectrum. In order to

develop the latter approach, we are studying data on the spectra of neutrons escaping from a variety of reacting cores and moderating and shielding materials. The conventional approximation of an unmoderated fission spectrum and '1/E' component is often seriously in error. Both measurements and calculations of spectra in this energy region, made for reactor physics purposes, have improved considerably in the last few years, and the results are generally in good agreement. From these results it appears that, in several important criticality situations, the escape spectra depend primarily on the moderating material (and to a much smaller extent on its geometry and thickness) and that simple calculations will determine these spectra with adequate accuracy for estimating fast neutron doses from neutrons below 500 keV. The objective of our work is to develop a simple and rapid method for estimating the dose delivered by such neutrons, from a knowledge of the moderating materials and from dose measurements made at higher and lower energies. Such estimates should help to reduce the uncertainty in the neutron dose delivered to individuals exposed in a criticality accident to the recommended value of less than 25 percent.

5.0799, DEVELOP ELECTROMAGNETIC HAZARD METER
R.R. BOWMAN, U.S. Dept. of Commerce, Natl. Bureau of Standards, *Boulder, Colorado*

Objectives: To extend the development of a new type of E-M hazard meter for use by the Navy on board ships. In FY 70 we developed a prototype meter that has unique characteristics even though it is not yet optimized. It has nearly perfect isotropic response; a dynamic range of 0.2 mW/per sq. cm to 2000 mW/per sq. cm; is broadband from 3 GHz to some as yet undetermined frequency below 1 GHz; has a 90 percent response time of less than 300 microseconds accurately measures fields with arbitrary polarization, multipath components, and re-active near-field components; does not perturb the field being measured; is virtually burn-out proof and is small, lightweight, inexpensive, rugged, and battery operated (low-drain). EM hazard meters with such capability are urgently needed in both the military and civilian areas. The present effort is to extend the frequency range to 6 GHz or more, improve the response time to less than 30 microseconds, improve the sensitivity, and improve and simplify the circuitry. This development will have great impact on research into the effects of EM fields on humans and other biological subjects as well as vastly improving survey measurements of hazardous EM fields. The meter is also very useful for many measurements for EM capability.

Approach: To fully realize the capabilities of this new type of meter, radical changes are necessary in the telemetry lines used to transmit the signal from the sensor to the instrument case. However, time and funds will not permit this development. Instead, the present type of telemetry line will be re-designed and optimized to allow an anticipated improvement of at least ten times in the response speed of the instrument. New circuitry will be developed to handle the increased signal speed. Also, the sensor size will be reduced by a factor of two by using ultra-miniature beam-lead diodes and a new design.

Outputs Expected: Greatly improved instrumentation for research into the biological effects of EM fields and for survey measurements of hazardous EM fields. Indirect: Instrumentation for some electromagnetic compatibility measurements (for instance, ordinance detonation problems on board ships); more effective control of EM pollution.

SUPPORTED BY U.S. Dept. of Commerce - N.B.S.

5.0800, HIGH FREQUENCY ELECTROMAGNETIC HAZARD MEASUREMENTS
R.R. BOWMAN, U.S. Dept. of Commerce, Natl. Bureau of Standards, *Boulder, Colorado*

Objective: (1) Develop probes and the associated instrumentation and measurement techniques required for a variety of tests involving the exposure of monkeys to high intensity pulsed EM fields. These tests are being conducted by the USAF School of Aerospace Medicine (USAFSAM) in order to determine the biological hazards to personnel exposed to strong EM fields. The needed instruments are not available commercially. (2) Provide technical consultation to USAFSAM in support of their overall study program. As a result of this work, NBS will enhance its ability to perform EM field measurements under difficult near-field conditions and considerable knowledge of the biological effects of EM radiation will be gained.

Approach: During FY 70 both fixed and portable E-and-H field probes were developed for measuring pulsed EM fields from 200-2000 v/meter over the frequency range 10-30 MHz to an accuracy of 1 DB. USAFSAM has requested that we modify these probes to measure up to 10,000 v/meter. This will be accomplished by modifying the plug-in capacitive divider network of the fixed probe and by reducing the sensitivity of the portable probes. We will also study the feasibility of constructing a phantom dosimeter and a miniature implantable probe for measuring the fields inside a body. The main technical problem will be the development of a suitable transmission line or telemetering

scheme to extract the information from the probe. Consultation will be provided on the design of the USAFSAM experimental apparatus and a theoretical study of possible resonance effects in people may be undertaken.

Outputs Expected: Specialized field strength measuring instrumentation and a greater understanding of the potential hazards of EM radiation.

SUPPORTED BY U.S. Dept. of Commerce - N.B.S.

5.0801, GAMMA-RAY SPECTROMETRY

J.A. PITKIN, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

Area(s) to which the work listed herein pertains: U. S.

Airborne and ground gamma-ray spectrometer surveys measure the components of natural terrestrial radioactivity and apply their relative distributions to geologic studies. These studies emphasize aiding geologic mapping; however, the application of spectrometer surveying to mineral exploration, both radioactive and nonradioactive, is being investigated.

Principal tools will be computer-produced contour maps of both radioelement and radioelement-ratio quantities. Initial studies to be made in areas of well-known geology and geochemistry, and later extended into less well known areas as experience is gained.

Long range goal is to establish gamma-ray spectrometer surveys as a meaningful geologic tool in most geologic provinces.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

5.0802, RADON PROGENY INHALATION STUDY

K.J. SCHIAGER, Colorado State University, School of Veterinary Medicine, *Fort Collins, Colorado* 80521 (AT(11-1)-1500)

Objectives: To investigate the relationships between the physical characteristics of airborne radon progeny in uranium mines and their deposition patterns in the human respiratory tract; to evaluate methods of measurement and control of inhalation exposures to uranium miners.

Scientific Background: Radon progeny nuclides have been found to exist as submicron aerosols in uranium mine atmospheres; upon deposition in the tracheobronchial tree, these aerosols may produce substantial alpha-particle exposures and are believed to be the cause of the excessive incidence of lung cancers observed in uranium miners.

Procedures: Analyses of aerosol particle-size distributions in uranium mine atmospheres, under various working conditions and ventilation patterns, will be made with diffusion tube batteries and a variable gradient thermal precipitator which is being developed. The exposure conditions in a mine will then be correlated with patterns of aerosol deposition in the respiratory tract determined by in vivo gamma- ray counting of subjects exposed either in actual mine spaces or in a laboratory exposure chamber.

Results: Measurements of radon concentrations and radon progeny concentrations and particle-size distributions were made during various operating and shut-down conditions along a complete ventilation route in an operating mine. Seven locations, from the air inlet shaft to the exhaust vent raise, were studied. Variations of exposure conditions along the air course were investigated as a function of the time of day and the nature of the mining operations being performed.

5.0803, RADON PROGENY EXPOSURE CONTROL IN BUILDINGS

K.J. SCHIAGER, Colorado State University, School of Veterinary Medicine, *Fort Collins, Colorado* 80521

The overall objective of this research is to devise and evaluate methods for treating or modifying structures so as to eliminate, or at least significantly reduce, the radon progeny inhalation exposures to occupants of the buildings caused by uranium mill tailings used as fill under or around the buildings. The types of structures to be used for the evaluation are typical of commercial and residential buildings found in Grand Junction, Colorado. The exposure control methods to be evaluated will range from simple, inexpensive methods to complex methods just short of demolition of the buildings. This study is expected to provide methods for eliminating any biologically significant exposures to people who live or work in buildings having abnormally high radon progeny concentrations as a result of the mill tailings used in construction.

5.0804, STUDIES OF APPLICATIONS OF RADIOISOTOPES FOR PROCESS CONTROL AND POLLUTION ABATEMENT

R.A. MICHELSON, Whyco Chromium Company Inc., *Thomaston, Connecticut* 06787 (AT-(30-1)-4008)

Whyco Chromium Company, Inc., under Contract No. AT(30-1)-4008, is undertaking the study of the feasibility of using low-level tracer radioisotopes as the measuring parameter in a chromium recovery unit, utilizing a cation exchange system for the removal of metallic impurities from chromium-plating baths. A radioisotope, such as Zn-65, will act as a metallic contaminant and be retained on the ion exchange resin. Both loading of the resin and eluting from the resin will be controlled by the use of such a radioisotope tracer. The advantages of using such a tracer has greatly improved operation of the ion exchange bed plus minimizing the amount of acid necessary to elute the bed, thereby effecting a savings in operation. This technique was proven to be feasible in a previous contract and was proven to be economically sound and having a cost advantage. The present system will apply the principles to a 400 gallon per hour evaporative system utilizing a cation exchange resin of from eight to sixteen cubic ft. capacity.

5.0805, BIOLOGICAL INDICATORS OF RADIATION INJURY

Z. DIENSTBIER, Univ. Karlova, *Prague, Czechoslovakia*

In agreement with the conclusions of the Panel on Biochemical Indicators of Radiation organized by IAEA and by WHO in June (Paris) a separate study of deoxycytidine excretion by urine, chromosomal changes in bone marrow and the activity of lysosomal enzymes in blood serum after irradiation will be carried out. Various kinds of animals will be used in order to prove the specificity of these changes and the dependence on the dose.

Within the course of the year these changes will be under observation in the same species of animals in order to compare their sensitivity after the application of individual radiation doses. The results will be compared also with hematological changes after irradiation because of the fact that these are elaborated in most details. Due to the possibilities, the changes indicated above will be further studied in individual cases in chosen, locally irradiated patients.

5.0808, RADIATION PROTECTION AND MEASUREMENT

L.S. TAYLOR, Natl. Coun. on Rad. Protectn., *Washington, District of Columbia* 20008

It is proposed that the work for the period 1/1 to 12/31/70 will be a continuation of that in which the Council was engaged during 1969, which work is described below: 1. Basic radiation protection criteria. 2. Specification for radium substitute. 3. Protection against neutron radiation. 4. Monitoring methods and instruments. 5. Incineration of radioactive waste. 6. Shielding against accelerator produced radiation. 7. Exposure from patients with radioactive materials in their bodies. 8. X-ray protection in dental offices. 9. Radiation protection in veterinary practice. 10. Dosimetry models for strontium. 11. Radiation protection in the use of small neutron generators. 12. High energy X- ray dosimetry. 13. Medical X and gamma-ray protection. 14. Radiation exposure from consumer products.

5.0809, THEORETICAL DOSIMETRY AND RADIOLOGICAL PHYSICS

M.J. BERGER, U.S. Dept. of Commerce, Natl. Bureau of Standards, *Washington, District of Columbia* 20234

Theoretical studies and calculations in dosimetry, radiation effects, and penetration of electrons and photons. Included are: calculations pertinent to absorbed-dose calibrations; determination of the response functions of solid state detectors; development of cavity- chamber theory; dosimetry of gamma and beta rays from internally administered radionuclides; microdosimetry calculations for electrons and photons; investigation of charged-particle track structure for the evaluation of radiation effects; determination of radiation quality (spectra, LET distributions, etc.) in irradiated media; transmission of electrons through shields; production of bremsstrahlung and photoneutrons in thick targets. The results will find application in medical dosimetry, manufacture of radiation detectors, and shielding of materials and people against radiation.

SUPPORTED BY U.S. Dept. of Commerce - N.B.S.

5.0810, RADIATION SAMPLING IN ANTARCTICA

A. SCHWEBEL, U.S. Dept. of Commerce, Natl. Bureau of Standards, *Washington, District of Columbia* 20234

This project is a continuation of the environmental radiological survey of the glacier area on which the nuclear reactor located at McMurdo Bay, Antarctica, empties its low level radioactive waste.

Twenty sampling sites will be selected. Twice yearly, 3 samples at each point, taken from varying depths, will be submitted for analysis.

All samples will counted for gross gamma emitters and a report submitted 30 days from receipt of the samples at NBS.

Selected samples will then be analyzed for specific radionuclides by gamma ray spectroscopy using solid state detectors. A rough estimate of the nuclides found will be submitted 60 days from receipt of samples. A final report based on a computer analysis of the data will be submitted 90 days after receipt of the samples.

A radiochemical assay of selected samples for such radionuclides as ^{90}Sr will be performed as necessary. Such analyses will be completed 120 days after receipt of the samples.

SUPPORTED BY U.S. Dept. of Commerce - N.B.S.

5.0811, CELLULAR PREDICTORS OF RADIOSENSITIVITY

H.L. CROMROY, Univ. of Florida, Graduate School, *Gainesville, Florida* 32601 (DAHC20-69-C-0291)

Technical Objective: Continue research with the objective of identifying biological indicators in food-web species which would serve as predictors of their radiosensitivity.

SUPPORTED BY U.S. Dept. of Defense - Army

5.0812, VISUAL CELLULAR STIMULATION BY HIGH ENERGY QUANTA

W.W. DAWSON, Univ. of Florida, School of Medicine, *Gainesville, Florida* 32601 (AT-(40-1)-3599)

The project will identify the retinal layers and cellular units responsible for the transduction of X-ray quanta into afferent information as transmitted by the optic nerve. It will examine further the relationships between retinal radiation pathology, local ischemia, vasomobility and the electroretinogram b-wave. It will explore the generality of the retinal transducer so that a beginning may be made toward the formulation of a body of theory which will treat ionizing ray induced changes in other portions of the nervous system.

Results to data: (1) Tests with physiologically equated X-ray and light stimuli produce distinct adaptation curves. (2) Mammalian eyes in the neuroblast stage of receptor development exhibit equivalent responses to X-ray and light stimuli. (3) Cone and rod receptors can atrophy under cold stress.

SUPPORTED BY U.S. Atomic Energy Commission

5.0813, TRITIATED HYDROGEN IN THE ATMOSPHERE - OF A NEW ULTRA-SENSITIVE TECHNIQUE FOR ENVIRONMENTAL SAMPLING IN NATURE AND INDUSTRY (ABBREV.)

H.G. OSTLUND, Univ. of Miami, School of Marine Science, *Miami, Florida* 33149 (AT-(40-1)-3944)

With our newly developed system, tritiated hydrogen in the atmosphere can be sampled in 5 to 40 minute intervals. The sampling can be performed at the laboratory or with a mobile unit, operated in an automobile or an aircraft.

With this system we want to monitor the atmospheric HT and HTO contents at two fixed stations in the United States. We want to establish if there are synoptic, vertical, and geographical variations in the HT concentrations. Background information will be collected on present environmental tritium levels in the vicinity of the Turkey Point nuclear power plant, now under construction on the shore of Biscayne Bay, Florida. Our input to the IAEA-WMO Global Tritium Network will be continued.

Results: Research work to start 15 May 1970. In previous contract year the sampling method was developed. It is based on adding tritium free hydrogen as carrier to the air, and catalytic combustion and absorption of the water on a Pd-Molecular Sieve catalyst.

5.0814, STUDIES IN THE USE OF IONIZING RADIATION AS STIMULI

J.C. SMITH, Florida State University, Graduate School, *Tallahassee, Florida* 32306 (AT(40-1)-2903)

Conditions under which animals make both immediate and delayed behavioral reactions to beta, gamma and X-rays will be explored. Three types of experiments will be conducted. 1. A pigeon, rat or monkey can be trained to suppress some ongoing response such as lever pressing by using X-rays as a warning stimulus for electric shock. This X-ray detection has been thought to depend solely on olfaction, but recent evidence indicates that vision also plays a role. Using anosmic animals, the conditions under which an animal can 'see' X-rays will be studied. 2. Gamma rays are aversive to the rat, i.e., if a preferred taste solution is presented and sampled during irradiation, this solution is avoided on subsequent presentations. This year we will determine the time intervals necessary for the pairing of the taste substance and the gamma rays, i.e., how long does the rat have to have access to the fluid (one lick or many minutes), how long the exposure (exposure rate) and the interaction of these times. In addition, a detailed analysis will be made on the development of the aversion by the use of lick measuring circuits and a computer. 3. Work will

continue studying the response of the eye of the moth Heliothesis Zea to beta and gamma rays and light. Some behavioral work will be conducted, but most of the data will be collected using the electroretinogram.

Results: Radiation perception has been shown to be mediated by the olfactory sense and the visual sense. In addition, there seems to be some radiation detection mediated by the humoral system with the abdominal area most sensitive. Exposure rate thresholds for X-ray detection are as low as 3-8 mr/sec in rhesus monkeys. A moth has been shown to respond to a pulse of X-rays to a total exposure of 0.25 mr.

SUPPORTED BY U.S. Atomic Energy Commission

5.0815, USE OF IONIZING RADIATIONS AS STIMULI

J.C. SMITH, Florida State University, Graduate School, *Tallahassee, Florida* 32306 (AT-(40-1)-2690)

Work has been conducted demonstrating the conditions under which animals can elicit an immediate reaction to the onset of an X-ray beam. It has been shown that both the visual and olfactory system are involved in this 'ionizing radiation perception' in pigeons, rats and rhesus monkeys. In addition, work has been conducted showing an immediate response by the moth to beta, gamma and X- rays.

It is proposed that work be continued studying the perception of X- rays by living organisms. Specifically, the proposed work will be divided into two areas: 1. Further studies of the role of vision in X- ray detection and, 2. further studies of the use of ionizing irradiations to condition aversions to taste solutions.

1. It has been shown that the anosmic rat cannot detect X-ray in the presence of high illumination. Rats will be made anosmic by ablation of the olfactory bulbs and will be trained to respond to X-rays in total darkness. Illumination levels will be manipulated and X-ray exposure- rates will be determined at each illumination level. In addition, these anosmic rats will be trained for X-ray detection in various monochromatic illuminations in an effort to ascertain which wavelengths most inhibit the X-ray detection. It is hoped that these studies will help in the understanding of how this X-ray detection is mediated by the visual route. 2. Solutions such as saccharine, are avoided by the rat if they have been previously presented one time in the presence of a sublethal X or gamma ray exposure. Animals exposed to water in the presence of the ionizing rays or animals which are sham exposed drink the saccharine in large quantities. Studies will be continued in our effort to understand this rather prompt aversive aspect of irradiation. The maximum time interval between ingestion of taste substance and exposure which still results in aversion will be determined. Efforts will be made to determine the number of licks of the taste substance and the absolute total X-ray exposure which is required to produce the aversion. Attempts will be made to relate these aversion studies to the typical anorexia noted in radiation therapy patients.

5.0816, RADIOACTIVE TRACER STUDIES OF SOIL AND LITTER ARTHROPOD FOOD CHAINS

D.A. CROSSLEY, Univ. of Georgia, School of Agriculture, *Athens, Georgia* 30601 (AT-(40-1)-3859)

Soil and litter arthropods contribute to breakdown and decomposition processes of dead organic matter in soils, but their importance remains poorly understood. Radioactive tracer techniques permit the measurement of mineral and energy transport along soil arthropod food chains. Input-output models are used to describe the accumulation of radioisotopes in links of food chains, as a means of estimating rates of trophic exchange among biota. Laboratory studies are comparing radionuclide excretion patterns of soil arthropods with those previously reported for above-ground herbivorous arthropods. Field research is centered on granitic outcrop ecosystems of the Georgia piedmont, which are known to accumulate concentrations of fallout radionuclides. Microcosm studies using pine needle litter or soil from granitic outcrop 'island communities' are utilized in describing transient behavior of radioisotopes in arthropod food chains.

Results: A set of samples of soils and biota from granitic outcrop ecosystems has been prepared and is awaiting analysis. Studies of radionuclide turnover by microarthropods have demonstrated comparatively low assimilation and slow excretion of radiocesium.

5.0817, RADIATION LEVELS FROM RADIOISOTOPE THERAPY PATIENTS

A.F. DRATZ, U.S. Veterans Administration, Hospital, *Atlanta, Georgia* 30329

Our study of radiation levels in the rooms of patients following oral I-131 therapy has been completed and a manuscript for publication is being prepared. Ambient radiation level measurements were corrected for decay to the time for I-131 administration, and expressed in mr-cm squared/mCi(adm)-hr dose rate units to normalize for the dosage administered and distance from the point of maximum activity. A highly significant correlation was found to exist between 24 hour thyroid uptakes done before therapy and dose rate measurements taken one to four days after therapy. Linear regressions of dose rate on thyroid uptake for both one day and pooled 2-4 day data indicated that if 100% of the I-131 were concentrated in the thyroid, the ambient radiation level (with 95% confidence limits) would be 2200 plus or minus 850. These regressions also indicated that if the thyroid uptake is 0%, the radiation level would differ significantly from zero, having mean values of 615 and 245 units, respectively, for the one day and pooled 2-4 day data. When allowance is made for geometry, these activity levels represent at least 40 and 16%, respectively, of the administered dose. These non-thyroidal iodine levels acquire additional importance when one considers the fact that patients with thyroid carcinoma and low uptakes usually get the highest administered doses.

Radiation level measurements taken shortly after I-131 administration had a mean and 95% confidence limits of 1600 plus or minus 865 dose rate units. These radiation levels are lower than those observed at later times near patients having high thyroid uptakes due to the difference in the relative distribution of I-131.

A nomogram incorporating these data has been designed. It provides a simple means for predicting, prior to therapy, what the radiation levels will be near the individual patient. Such predictions can obviate undue restrictions on both bedside care and isolation of hospitalized patients. They also will provide a more specific basis from which to make recommendations to the families of those patients not hospitalized for I-131 therapy.

5.0818, TRACING RADIONUCLIDES IN HUMANS AND ANIMALS BY HELICAL SCANNING

J.I. ANDERSON, U.S. Atomic Energy Commission, Health Services Laboratory, *Idaho Falls, Idaho*

The object of this investigation is to provide a more accurate method for measurement of quantity and distribution of various types of radioactive contaminants in the body, and to utilize this method to determine the fate of these contaminants as a function of their physical and chemical states and mode of entrance into the body.

Previously animal experimentation has been used for establishing most of the criteria for the calculation of internal dose from radioactivity in men. The purpose of this study is to determine better parameters for this calculation from results of actual human exposures. Gamma emitting nuclides in various states will be traced in humans and animals by helical scanning and rectilinear scanning. Large areas of the body will be scanned by detectors that rotate around the body to determine the sites of increased gamma-ray intensity. Once these positions on the body are determined, section scans will be done with high-resolution focusing collimaters to further localize the nuclides in specific organs of the body. The results will be a determination of translocation of radioactive elements and their associated materials in the body from the blood stream, pulmonary system and digestive system.

SUPPORTED BY U.S. Atomic Energy Commission

5.0819, THE DETERMINATION OF PLUTONIUM 239 IN LUNG TISSUE BY ACTIVATION ANALYSIS

D.G. OLSON, U.S. Atomic Energy Commission, Health Services Laboratory, *Idaho Falls, Idaho*

The detection limit for plutonium-239 can be lowered significantly by fissioning the plutonium and measuring the activity of a specific short-lived fission product. For example, 20 disintegrations per hour of plutonium-239 irradiated in a neutron flux for 18 hours will yield 1000 disintegrations per minute of zirconium-95. A large share of the plutonium released to the atmosphere has been high-fired and will not dissolve in body fluids; therefore plutonium taken into the lungs may remain there for long periods of time. Such a system might provide a method of monitoring lung levels arising from sources such as fallout.

The lung is decomposed with acids and the plutonium separated from the remaining inorganic salts by liquid extraction. Plutonium is then precipitated and collected on bismuth phosphate. The phosphate precipitate is dried on a polyethylene film which is then irradiated in a neutron field. After irradiation the sample is decomposed in acids and zirconium separated out for counting. The number of plutonium target atoms is then calculated from the known neutron flux, cross section, fission yield and irradiation time. Preliminary work using elk and deer lung tissue is in progress.

SUPPORTED BY U.S. Atomic Energy Commission

5.0820, SEQUENTIAL RADIOCHEMICAL DETERMINATION OF RADIUM-226, 228, ACTINIUM-227 AND THORIUM-230 IN ENVIRONMENTAL AND PROCESS WASTE SAMPLES

D. PERCIVAL, U.S. Atomic Energy Commission, Health Services Laboratory, *Idaho Falls, Idaho*

A procedure has been developed for the sequential determination of radium-226, 228, actinium-227, and thorium-230 which permits their detection in a single sample at 0.1 to 0.001 of the concentration guides specified by federal regulations for uncontrolled areas. The increasing concern over possible pollution of the environment with these radioactive wastes from the uranium mining and milling industries makes the development of such a procedure most timely. The capability of performing several different analyses on a single sample provides a significant reduction in cost and analysis time.

An initial separation of the three elements from gross sample constituents is achieved by carrying them on lead sulfate precipitated from a system with high sulfuric acid and potassium sulfate concentrations. Subsequent separation of radium, actinium, and thorium from one another is simply and rapidly achieved by dissolving the lead sulfate with a complexing agent. Radium isotopes are separated from the solution on a small quantity of barium sulfate from which radium-226 and/or radium-228 are determined. Actinium-227 and/or thorium isotopes are then separated directly from the solution by extraction into an organophosphorous reagent under easily controlled pH conditions. The method is versatile since any one or more of the radionuclides may be excluded from the analysis by omitting certain independent steps, thus shortening the working time. Final studies on accuracy, precision, and the effects of both chemical and radiochemical interferences are presently being conducted. Determination of the radionuclides involves the use of alpha scintillation detectors, alpha spectrometers, beta counters, gross gamma counters and radon scintillation cells. The procedure has been tested on air dusts, up to 1000 ml of aqueous and up to 1 g of mill tailing or ores. Application of the procedure has recently been extended to 10-g soil samples and future efforts will be made to include vegetation, urine, feces, blood, tissue and bone ash.

SUPPORTED BY U.S. Atomic Energy Commission

5.0821, THE DETERMINATION OF PLUTONIUM IN SOIL

C.W. SILL, U.S. Atomic Energy Commission, Health Services Laboratory, *Idaho Falls, Idaho*

The sensitive and reliable determination of plutonium in soil is becoming increasingly important because of the public attention being focused on current radioactive waste burial practices and the public health impact of releases of plutonium to the environment. Because of the high sensitivity required, large samples must be used which introduces certain difficulties. Plutonium oxide is an extremely refractory material, particularly when heated strongly, and requires very powerful methods of attack for its complete and reliable dissolution. Reliability requires that a method be used that gives complete decomposition of the siliceous matrix with complete elimination of insoluble material and that guarantees complete conversion of the plutonium to a soluble monomeric ionic form capable of undergoing chemical reactions characteristic of plutonium before any separations are attempted. Any procedure giving less than complete sample decomposition is almost certain to give low and erratic results for plutonium when applied to these complex materials. At best, the reliability of the determination would remain in doubt. Most available analytical procedures applicable to adequately large samples depend on selective leaching with acids to remove plutonium from the insoluble matrix. Use of a tracer such as plutonium 236 is obviously of no assistance in correcting for the quantity of plutonium remaining undissolved.

Results: The present procedure has been designed to permit total decomposition of soils using the combined potassium fluoride and pyrosulfate fusions with subsequent volatilization of both fluoride and silica. The large alpha-emitting ions present in the solution are then precipitated on barium sulfate and combined with those present in the barium sulfate indigenous to the sample. The entire problem then reduces to one of separating the plutonium from the single compound sulfate for which several excellent procedures are available.

SUPPORTED BY U.S. Atomic Energy Commission

5.0822, INSTRUMENTATION FOR IN VIVO DETERMINATION OF INSOLUBLE PLUTONIUM IN THE LUNG

M. WILHELMSEN, U.S. Atomic Energy Commission, Health Services Laboratory, *Idaho Falls, Idaho*

The objective is to research and develop instrumentation for the in vivo detection, identification and quantitative determination of radioactive plutonium in the human lung. Such instrumentation is needed since more people in the atomic energy industry are working with plutonium and since determination of dose is essential to the control of personnel in hazardous areas.

As isotopes of plutonium are alpha emitters with about 4 percent of the alpha-particle events producing X-rays in the 10 to 20 KeV energy range, the basic problem is one of detecting and counting the low energy X-rays at intensities lower than maximum permissible lung-burden levels. Because of the low X-ray field and high absorption by the chest-walls, an extremely sensitive detecting system is required.

Results: Special self contained gas proportional counters have been designed and purchased from a company which custom-built them according to specifications. A small computer has been programmed to enhance data gathering and processing. Plotting, recording and printing peripheral units have been interfaced to the systems. Evaluation of the system is in progress. The immediate objective is to build a practical operational detector if the system proves satisfactory as expected.

SUPPORTED BY U.S. Atomic Energy Commission

5.0823, GROSS ALPHA DETERMINATION IN ENVIRONMENTAL AND BIOLOGICAL SAMPLES

R.L. WILLIAMS, U.S. Atomic Energy Commission, Health Services Laboratory, *Idaho Falls, Idaho*

The objective of the present research is to develop procedures which can be used to determine the alpha activity in

all environmental and biological samples. A quantitative as well as a qualitative analysis is desired for all alpha emitters from radium to californium, including polonium and bismuth.

An increasing interest in determining smaller and smaller amounts of alpha activity in samples has led to this investigation. The basic problem in analyzing samples that have a very low alpha activity is that the sample size must increase, thereby increasing the problems of decomposition and interferences in subsequent chemical separations.

The decomposition consists of wet ashing with nitric and perchloric acids to remove organic materials, followed by a combination of potassium fluoride and sulfate fusions to dissolve siliceous materials and refractory compounds with simultaneous volatilizations of hydrogen fluoride and silica. The alpha activity is carried out of solution on barium sulfate with individual elements being separated or a gross alpha obtained by selective oxidation or reduction. The barium sulfate is deposited uniformly on a vinyl metricel filter, covered with a zinc sulfide phosphor and counted in a scintillation counter. After counting, the barium sulfate is dissolved, the alpha activity electro- deposited, and an alpha spectrum obtained, thus producing both a quantitative and qualitative alpha analysis of the original sample.

Results: Methods for using up to 10 grams of soil, bone, blood, feces, urines, ores and liquid effluents are being developed for alpha analysis. A method is presently under investigation which would deposit the alpha emitters uniformly on a plate as the hydroxide. This hydroxide precipitation would allow scintillation counting as well as alpha spectrometry without further treatment. Samples of up to 1000 milliliters of liquids and 50 milligrams of solids (soils, sediments and ores) have been analyzed with a recovery of better than 99.95%.

5.0824. SOLID STATE RADIATION DOSIMETRY

J. KASTNER, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

Solid state detectors of small dimensions could prove useful as receptors of microdosimetric information, especially in vivo.

An effort has been made to correlate the spectrum of the light from thermoluminescent materials with various kinds of ionizing radiations. It has been determined that the spectrum of LiF is different for alpha rays than for electrons.

Results: Electro-optical equipment was designed and assembled in conjunction with a UV laser to carry out sensitive fluorescent decay studies on a variety of radiophotoluminescent material. It is possible to use time discrimination to reduce the intrinsic background luminescence of silver doped glass.

SUPPORTED BY U.S. Atomic Energy Commission

5.0825. LOCALIZATION OF LOW CONCENTRATIONS OF GAMMA RAY EMITTERS IN MAN

L.D. MARINELLI, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

Localization of gamma-ray emitters is essential to the clarification of effects produced by internal emitters. Its realization in vivo by means of time-of-flight techniques has been investigated by measuring at the ends of a scintillating rod the difference in time of arrival of light from scintillations produced by gamma-radiation anywhere along the rod.

The principles of light transmission by plastic rods and of the time resolution ensuing from scintillations within it have been investigated. The influence of the following factors has been studied: a) type and dimensions of plastic rods, b) the type of photomultiplier, and c) the fraction of the light pulse utilized. Some difficulties have been experienced in the electronic stability of a multi-rod system. The possibility of using very fast liquid scintillators has been considered and to this end, the optical properties of various solutes have been studied.

A beginning has been made in the problem of determining the radioactivity in vivo from the scintillation distribution in the rod. The properties of various experimental parameters (including collimation) entering into the pertinent Fredholm's equation are being investigated.

Results: Fairly satisfactory resolutions have been obtained with lengths up to 3' and cross sections of 2' with either a 8575 or a C31000D photomultiplier. Some satisfactory solutions to Fredholm's equation have resulted.

SUPPORTED BY U.S. Atomic Energy Commission

5.0826. FLUX AND SPECTRUM OF FAST NEURTONS IN NATURAL ENVIRONMENT

B.G. OLTMAN, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

Instrumentation and techniques necessary to determine quantitatively the neutron component of the environmental radiation to which man is exposed are being developed. The range of neutrons below about 2 MeV is being explored by means of hydrogen gas counters and by Li6 loaded scintillators. The thermal neutron flux is being measured by means of etched-tract sandwiches consisting of either U-235 and mica or Li6/B10 and plastic foils. The effect of soil and water on neutron environment is being evaluated and compared with theoretical prediction. Based on our results, we have proposed a passive soil moisture meter.

SUPPORTED BY U.S. Atomic Energy Commission

5.0827. SINUS DOSIMETRY IN RADIUM POISONING CASES

R.A. SCHLENKER, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

Sinus carcinomas in radium cases appear to result from the bombardment of sinus epithelium by alpha particles from underlying radium-bearing bone. In order to evaluate the dose rate in sinus epithelium, the energy distribution of alpha particles emitted from the surfaces of sinus bone samples is measured in vitro using semiconductor detectors. The in vivo energy distribution is determined from the in vitro distribution by using assumptions about the behavior of radium and its daughter products in bone. The dose rate to the overlying epithelium is calculated from the in vivo energy distribution.

Results: Preliminary results are that the dose in sinus epithelium averaged throughout the time of radium burden is greater than 1 rad/day, and the total dose from the time of initial burden to death is greater than 10,000 rads.

SUPPORTED BY U.S. Atomic Energy Commission

5.0828. RELATIVE BIOLOGICAL EFFECTIVENESS

W.K. SINCLAIR, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

This project concerns the establishment of the relative biological effectiveness of various ionizing radiations of differing physical properties and their rise in developing theories of radiation action. Information is collected on various endpoints in various test systems and results related to various physical parameters, primarily linear energy transfer (LET), for determining mechanisms of action. In addition, specific investigations with monoenergetic neutrons and with fission neutrons are undertaken in test systems such as (1) testes weight loss in the mouse, (2) mammalian cells in culture using survival, division delay and chromosome aberrations as endpoints, (3) lethality in the mouse, (4) lethality in Tribolium larvae, (5) growth inhibition on seedlings of Hordeum.

Results: Computations of LET spectra and various energies of neutrons and californium 252 have been made. Contributions have also been made to the determination of which physical parameter to use in describing the variation of biological effectiveness with physical properties of the radiation. RBE studies in all of the test systems indicated above have been conducted at one or another neutron energy or spectrum and some unnusual features noted which indicate that RBE studies in a wide range of endpoints over a broad neutron energy range (and LET range) could be most informative.

5.0829, PHYSICAL AND PHYSIOLOGICAL COMPONENTS OF RADIATION EFFECTS IN CELLS
R.B. WEBB, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

Parallel studies are being made on the dormant bacterial endospore and nondormant vegetative cells to distinguish physical and chemical events from metabolic processes in X-ray effects on biological systems. The dormant bacterial endospore is unique in that it shows an extremely low level of metabolic activity, even in the fully hydrated state, until germination is induced. Modification of the radiation response of the dormant endospore by physical and chemical treatments likely affects chemical and physical events rather than metabolic processes.

Oxygen enhancement, nitric oxide enhancement and protection, carbon monoxide sensitization, protection by sulfhydryls and alcohol in the X- ray inactivation of the spore of 'Bacillus megaterium' and the nondormant cells of various bacteria are studied over a wide range of controlled hydration levels. Complete dose response curves are obtained using the ability of the cell to produce a visible colony as the primary biological end-point.

Results: At equilibrium aqueous vapor pressures below 5 torr cells of 'Staphylococcus aureus' show a pattern of response to X-rays very similar to that of 'B. megaterium' spores, suggesting that inactivation mechanisms are the same in both systems. The two systems differ somewhat in their X-ray response above 5 torr. Both nitric oxide and carbon monoxide substantially increase the X-ray sensitivity of 'S. aureus' at hydration levels above 5 torr, when the gas is present during irradiation. In this range nitric oxide has only a small sensitizing effect on the spore. Carbon monoxide has no effect on the spore. These results implicate metabolic processes in the sensitizing effects of carbon monoxide and nitric oxide on the X-ray response of 'S. aureus'.

5.0830, DOSIMETRY
F.S. WILLIAMSON, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-eng-38)

Evaluates the absorbed dose to biological specimens in common exposure situations for X and gamma rays and neutrons, so that standard factors may be derived to determine absorbed dose in these circumstances. The goal is to assure that informaton needed for a given experiment may be obtained from a single measurement. While calculations can establish a relation between absorbed X- and gamma-ray dose and exposure (rads/R), uncertainties become numerous in larger animals. Chemical dosimeters in polyethylene containers simulate the range of exposure volumes, and doses are determined as a function of volume. Maximum and minimum doses, as a function of volume, are measured from small vials in front and behind each vessel. Absolute values for neutron absorbed dose rate will be attempted by calorimetry; calibration of our ionization chambers against Pu-Be and Po-Be (or Am- Be) standards; against calibrated tissue-equivalent chambers of the Rossi type; and by comparison of Hurst counters, HF3 counters, and gel chambers, at necessary representative points. Studies of depth-dose distribution in tissue-equivalent phantoms of various sizes are studied and phantoms correct in both geometry and composition. The distribution of absorbed dose due to gamma rays from internal emitters in large animals is examined theoretically, starting with the geometrical factor approach and modifying for various conditions of scatter.

Results: Major effort has been directed at completion of the modified JANUS biological reactor for neutron toxicity studies. The reactor operated at low power (December 1969) and at full power--200 MW (March 1970). Magnesium ionization chambers of 0.05 cc collection volume with argon gas filling will be used in conjunction with tissue- equivalent version to resolve neutron and gamma-ray depth doses within mouse phantoms. Monte Carlo computations of neutron and gamma-ray depth doses and LET distributions in mouse phantoms have been completed.

5.0831, PRACTICAL HIGH SENSITIVITY THERMOLUMINESCENT DOSIMETRY
R.M. JOHNSON, U.S. Veterans Administration, Research Hospital, *Chicago, Illinois* 60611

Results: The results of this project have been to develop an instrument capable of measuring the light output from irradiated crystals of various insulating materials (calcite, LiF, CaF2, Li2, B204, and commercial thermoluminescent dosimeters now available). This light output has been proved proportional to the amount of ionizing radiation received. The proportionality has been shown here to hold over a temperature range of irradiation from liquid nitrogen temperature to room temperature.

The apparatus developed may be used with a broad range of physical formats for the active material including loose powder, silicone rubber discs, extrusions, pressings, crystal chips or commercial packaged glass tubes with internal material. This equipment is usable therefore for measurement of X or gamma ray doses in body cavities for therapy purposes or for measurement of the lower doses encountered in routine work with radioisotopes or diagnostic X-rays.

Presentations: The original instrument design conceptions were reported at a meeting of the Radiological Society of North America and the later work with a range of phosphors at cryogenic temperatures was reported at the Midwest Chapter Meeting of the American Association of Physicists in Medicine.

Terminated due to the resignation of the investigator.

SUPPORTED BY U.S. Veterans Administration

5.0832, TOTAL-BODY COUNTING FACILITY
D.B. CHARLESTON, Univ. of Chicago, School of Medicine, *Chicago, Illinois* 60637 (AT(11-1)-69)

The scope of this project embraces the development of the total- body counting facility with a flexible quantitative imaging device and its use in metabolic studies in laboratory animals and human beings. These include investigations of factors that stimulate hyperplasia of the parathyroid glands such as pancreatic inflammation and thiazide diuretics; investigations of calcium kinetics in various disorders of calcium metabolism, retention and dosimetric studies on developmental radiopharmaceuticals.

A single linear camera scintillation detection system will replace the 4 separate detectors presently in use for whole-body scanning as soon as the necessary funds are available.

Results: Studies on the metabolism of calcium showed that ablation of the thyroid gland in rabbits abolishes the hypocalcemic action of glucagon; that prolonged administration of thiazide diuretics to dogs produces hypertrophy and hyperplasia accompanied by increased serum calcium, decreased serum PO4 and increased Se75 uptake by the glands; that there is a marked decrease in urinary Ca and PO4 in dogs when thiazides are administered.

5.0833, PHYSICAL AND BIOLOGICAL INVESTIGATIONS OF HIGH ENERGY RADIATION DIRECTED MAINLY TOWARD THERAPY
L.H. LANZL, Univ. of Chicago, School of Medicine, *Chicago, Illinois* 60637 (AT(11-1)-69)

The purpose of this project is to evaluate the physical factors and biological effects of high energy radiations, especially electrons from the linear accelerator and to compare them with the more conventionally used X-rays and gamma rays. New methods of treatment planning are worked out.

Radiation dosimetry, computer uses, radiation protection and estimation of bone mineral changes are all part of the program.

Present problems involve installation of a carbon calorimeter for absolute calibration of radiation beams; manufacture of a patient- simulator and treatment planning device; installation of a simulator for treatment of large treatment fields such as those required for Hodgkin's disease.

Results: A remote terminal for calculation of dosimetry data has been acquired by lease and placed into service. An automatic contour measuring device for use with the cobalt-60 machine has been placed in routine service in the clinics. Further dosimetry studies for Hodgkin's disease have been carried out.

5.0834, THE PHYSICAL BASIS OF IONIZING-RADIATION ACTION

R.L. PLATZMAN, Univ. of Chicago, Graduate School, *Chicago, Illinois* 60637 (AT(11-1)-2100)

The objective of this research is the theoretical calculation and interpretation of yields of the initial ('primary') events in the absorption of various ionizing radiations by matter. These events are equally crucial for the physical, chemical, and biological action of the radiations. The work will start with 'electronic' radiations and a few representative varieties of matter. The first stage for each medium is assembly of a complete set of cross-sections for all relevant inelastic processes (excitation and ionization) induced in the atoms or molecules by electron impact, at all electron velocities. These will be obtained from analysis of optical data (oscillator-strength distributions) and of experimental cross-section determinations, together with theoretical calcualation. The electron degradation- spectrum will then be calculated. Initial yields will be calculated therafter from the cross- sections and the degradiation-spectrum. The first media studied will be selcted from among such simple gases as He, Ne, Ar, H2, CH4, and H2O. With degradation spectra that include the contribution of glancing collisions, as these will, the factors that determine the role of the degradation spectrum in establishing the qualitative and quantitative character of radiation effects will be sought. New knowledge of the primary events will eventually be applied toward elucidating the early temporal stages in the response of the medium to its exposure to radiation.

5.0835, DEVELOPMENT AND APPLICATION OF MULTICHANNEL SCANNING

E. KAPLAN, U.S. Veterans Administration, Hospital, *Hines, Illinois* 60141

Purpose: The selenated amino acids selenocystine and 75selenomethionine are under study to evaluate their localization and quantitative distribution to better understand the physiology and pathophysiology of these compounds. Plan: To determine effective biologic half life of the two selenated compounds using the whole body counter; to determine body distribution when comparing intravenous versus oral administration; to utilize dual channel subtraction and energy modulated color display to scan pancreas, myocardium and brain; to determine localization of selenocystine in the hypothalamus; to compare distribution of 75selenomethionine with distribution of 75selenomethionine labeled peptides. Results: The biologic half life of 75selenomethionine has been determined as a three phase curve consisting of 8 hours, 17 days and 93 days. The radiation exposure, whole body, for 250 Ci dose is determined as 1.63 rad. The I.V. versus oral route results in very similar distribution. After G.I. absorption is complete, the pancreas can be effectively scanned using the dual channel technique referred to. Selenocystine when injected into the carotid artery of the dog with 2.5% saline results in hypothalamic concentration of 12 to 1 as compared with the other areas in the brain. This has been visualized by scintiscanning. Preliminary comparison of selenomethionine distribution compared to selenomethionine peptides results in difference in quantitative localization.

5.0836, RADIOPROTECTIVE AND TUMORICIDAL EFFECTS OF TWO NEUROTROPIC DRUGS

J. LEVAN, U.S. Veterans Administration, Hospital, *Hines, Illinois* 60141

A number of substances classified as stimulants or depressants of the central nervous system (CNS) have been reported to possess radioprotective properties. While studying the effects of Magnesium Pemoline (M.P., 5-phenyl-pseudo-hydantoin), a mild CNS stimulant, on conditioned avoidance response using X-irradiation as an unconditioned stimulus: we observed significant radio-protection in mice. Further experimentation showed up to 40% survival in several groups of mice exposed to lethal whole-body X-irradiation: while none of the control animals survived 14 days. More significantly, an 18%/30 day survival was observed when M.P. was given shortly after lethal irradiation. We also found that M.P. had a cytotoxic effect on Ehrlich tumor cells, thus prolonging the life span of the tumor bearing animals.

Since M.P. is still an experimental drug in the U. S. we investigated the radioprotective potency of a chemically related compound already listed in the U.S. Pharmacopeia, namely: Diphenylhydantoin (DPH). DPH, in contrast to M.P., has an anticonvulsant, and depressive CNS effect. Laird and Fonner have reported a protective effect of DPH in mice exposed to high doses of irradiation which causes CNS death in the immediate period following exposure. We were able to demonstrate in our initial studies that DPH afforded a 60% survival at 30 days when given before 75 or X-irradiation, while no control animals survived. And similarly to the described tumoricidal effect of M.P., Ehrlich tumor bearing mice treated with DPH survived longer than untreated controls.

We propose to study the mechanism of radioprotection afforded by M. P. and DPH and evaluate their tumoricidal potential by studying preselected criteria as determinants of survival. The residual viability of the treated tumor cells will be tested by transplantation to an untreated group of mice.

Moreover, it was observed that both M.P. and DPH were overall more cytotoxic to leukemic than to normal lymphocytes. As expected, the survival of treated and untreated cells decreased with increasing doses of X- irradiation. But the initial results of combiningg DPH and X- irradiation showed a synergistic toxic effect on normal lymphocytes: while DPH treated leukemic cells seemed to be more radioresistant than control leukemic cells.

5.0837, SERUM OSMOLALITY AND INTRACRANIAL PRESSURE

A.P. REMENCHIK, U.S. Veterans Administration, Hospital, *Hines, Illinois* 60141

Application of the whole body counter has provided a means to quantify small amounts of radioactivity in the human body. This activity may indicate naturally occurring radionuclides, contamination from fallout or a deliberate administration of a tracer dosage of radionuclide to determine its absorption, elimination or metabolic behavior in specific context. This may be accomplished without trauma to the patient and does not require the collection of the particle excretions.

The specific studies proposed at the low level counting facility of this hospital are concerned with the employment of this system for more precise definition of several relevant problems exemplified below: 1. The study of vitamin B12 metabolism in Addisonian pernicious anemia and that associated with immunoglobulin deficiency. 2. The study of thyroxine metabolism and its partition between the vascular, extravascular, and cellular compartments. 3. The study of body content of potassium in congestive heart failure and hypertension. 4. The study of the effect of chronic hemodialysis upon trace mineral, iron and calcium metabolism. 5. The study and definition of individuals at risk for neoplastic disease.

5.0838, SPECIAL PROBLEMS IN NUCLEAR INSTRUMENTATION AND MEASUREMENT OF W IN GASES

F.R. SHONKA, Saint Procopius College, Undergraduate School, *Lisle, Illinois* 60532 (AT(11-1)-323)

Work has been completed on the isotope ratio for hydrocarbon gases as a function of alpha-particle energies in the range 5.8 - 1.6 MeV. For the hydrocarbons methane, ethane, acetylene, and ethylene there was found to be a very small increase of the order of 1% - 3% in the isotope ratio as one decreased the alpha-particle energy from 5 to 1.6 MeV.

The principle area of interest is the formulating of the materials which simulate muscle, bone etc. for all types of nuclear radiations and the construction of ionization chambers for precision measurements of radiation dose. These ionization chambers vary in ionizing volumes from 0.01 ml, used principally in measurement of high energy beams, to 16 liters, used for measurement of background and environmental radiation. This year our major advance had been made in the welding of the conducting plastic materials. These methods include; 1. heating of the parts to be welded under pressure in a closely fitted mold, 2. a torch blowing superheated gas instead of a flame, 3. the so called 'flying seal' method, similar to that used in glass blowing, 4. resistive welding by passing an electric current through the joint to be welded, 5. percussive welding by discharge of condensers through the joint to be welded, 6. ultrasonic welding, and 7. friction welding. Friction and sonic welding are our most useful methods.

5.0839, RESEARCH WITHIN THE FRAMEWORK OF A COORDINATED PROGRAMME ON NUCLEAR ACCIDENT DOSIMETRY

P.N. KRISHNAMOORTHY, Bhabha Atomic Research Centre, *Bombay, Mahrashtra, India*

Investigations will be continued on the use of appropriate foils for both area and personnel monitoring systems for accident dosimetric purposes.

Work on a foil-cum-plastic track recorder system for covering a large part of the intermediate energy neutron range which is already underway, will be continued.

Several chemical dosimetric systems for accident dosimetric purposes have already been developed. These systems are being tested under field conditions. Further investigations on the energy dependence, neutron response and time dependent stability characteristics will continue. In addition, investigations on the suitability of other chemical systems for accident dosimetric purposes are underway.

A number of indigenous glass and TLD systems which are being developed are being investigated for suitability for use in accident dosimetric systems. Some promising results have already been obtained. The reader systems for these dosimeters are also being locally designed and fabricated.

Studies have been initiated on activation analysis of appropriate elements present in the body such as sulphur in hair and nail, and sodium in the blood.

Some work has also been initiated in the promising area of TSEE systems to investigate its potential for accident dosimetric purposes.

5.0841, ISOLATION OF A FACTOR PREVENTING X-RAY INDUCED LEUKEMIA

M.E. HODES, Indiana University, School of Medicine, *Indianapolis, Indiana* 46202 (AT(11-1))

Fractionation of commercial Cohn fractions on DEAE-cellulose and Sephadex in order to isolate RLP, the radiation-leukemia protection factor, continue. The fractions are characterized by polyacrylamide gel electrophoresis and immunoelectrophoresis.

Whole serum, in addition to its leukemia-preventing properties, is able to reverse certain biochemical abnormalities that follow exposure to 200-300 r doses of X-ray. This ability is not shared by serum albumin and certain other serum proteins. The various fractions prepared for RLP testing are also being assayed for their ability to reverse these biochemical abnormalities. Particular attention is being paid to alpha-2-macroglobulin, a protein reported to have both leukemia- preventing and chemotherapeutic effects.

5.0844, DIRECT INTERNAL RADIATION DOSIMETRY OF RADIOPHARMACEUTICALS BY IMPROVED NEEDLE TYPE FLUOROGLASS DOSIMETER

M. HO, Univ. of Tokyo, *Tokyo, Japan*

Present internal radiation doses by radiopharmaceuticals have been calculated based on assumptions and the development of direct sensitive method is desired. Our group investigated the possibility of such direct in vivo measurement of internal radiation and, under the contract, is now performing the improvement of fluoro dosimetry.

In the first year new silver activated phosphate glass with smaller energy dependence and predose than the conventional one has been developed. Dimension was 1 mm and 6 mm in length. Because of its extremely small predose it enables one to measure such a low radiation dose as 3 m rad, provided that new equipment for this measurement is to be developed.

This new instrument was also constructed in the first year. By this the glass rod is able to be stimulated by the ultra violet light (365 mu) quite strongly. Most important improvements were the adoption of the ellipsoidal reflecting mirror as well as special mercury lamp.

Further improvement of dosimeter glass with higher sensitivity, lower energy dependence, smaller predose is being planned in the second year.

5.0846, EVALUATION OF THERMOLUMINESCENT DOSIMETERS AS A HEALTH PHYSICS TOOL
O.R. CZERWONKA, U.S. Veterans Administration, Hospital, *Louisville, Kentucky* 40202

Report on Major items of equipment to be used in this project: 1. A cobalt-60 irradiator facility was constructed adjacent to Animal Research Building No. 12. Construction was completed in February, 1969. The installation of a Bar-Ray Model M-FC, cobalt-60 unit capable of housing a maximum of 1000 curies of cobalt-60 was completed in April, 1969. To date this facility is pending final approval by the Atomic Energy Commission. 2. A Madison Research Thermoluminescent Dosimeter Reader System with Recorder and other accessories, including a variety of Lithium Fluoride Thermoluminescent Dosimeters have been received and presently are being standardized and calibrated.

Plans for Future Allied Research and Estimated Timing: 1. A complete survey of entire VA's film badge personnel monitoring methods will be made and a study for replacing current film badges with T.L.D.'S will be made and a report with recommendations will be completed. 2. Thermoluminescent Dosimeters will be standardized and selected for use in making dose determinations on all VA Hospital patients treated at the University of Louisville Radiation Center. Compilation of research data will include skin dose, tumor dose, vital organ dose and comparative data of T.L.D. vs present conventinal methods for patients receiving radiation therapy. 3. Thermoluminescent Dosimeters will be selected and standardized for use in personnel monitoring of occupationally exposed personnel. 4. Various items and tools will be developed for holding T.L.D.'S at precise sites within the human body, and for determining radiation field uniformity, isodose curves and primary beam outputs. 5. Possibility of working a mail order T.L.D. service into the regional medical program will also be explored. This service would be strictly centered around tumor dose and vital organ dose determinations of radiation therapy patients, and the results compiled and also submitted to the referring therapeutic radiologist. 6. A publication or report on the cobalt irradiator facility will be prepared during the coming year.

There has been a curtailment of research activity during this reporting period due mainly to the construction of facilities and the procurement of major equipment to be used for this research project. However, most equipment has been installed and is presently being standardized.

5.0850, THE MODULATION TRANSFER FUNCTION OF X-RAY SYSTEMS
R.H. MORGAN, Johns Hopkins University, School of Public Health, *Baltimore, Maryland* 21205

The aim of this research is the development of a standard method for the measurement of the spatial modulation transfer functions of radiological systems and/or system elements. Currently, methods for the measurement of this parameter yield results which are inconsistent from one laboratory to another. Because (a) the information transfer capability of a radiological system, (b) the extent to which quantum fluctuation may restrict this capability and (c) the patient exposure requirements of medical X-ray procedures are markedly influenced by modulation transfer function values, it is important that improved methods yielding reproducible MTF values be developed as soon as possible. Precise MTF data are a basic requirement of the design of systems which give maximum diagnostic information at minimum levels of patient exposure.

Recently, the International Commission on Radiological Units established a Task Group to stimulate research in methods to measure the spatial modulation transfer functions of radiological systems and, from this research, to develop an international standard by which such measurements may be carried out with a high level of reproducibility. This project constitutes one part of this international effort.

In this project, the factors which cause inconsistency in current methods of MTF measurement will be examined systematically and quantitatively. From the information gained from these studies, it is expected that within a three-year period enough data will be at hand to permit the formulation of the needed international standard.

5.0853, ELECTROMAGNETIC RADIATION MEASUREMENT METHODS AND CALIBRATION
G. ANDERSON, U.S. Environ. Protection Agcy., Twinbrook Research Laboratory, *Rockville, Maryland* 20852

Priority objectives of this program are to: 1) Develop laboratory exposure-calibration facilities for the electromagnetic spectrum bands of 1-10 MHz, 100-400 MHz, and 1-10 GHz as well as a field measurement system for these same frequencies. 2) Determine theoretical estimates of population exposure from electromagnetic radiation sources based on available data. 3) Develop and evaluate the use of liquid crystals, microthermocouples, and infra-red emission sensors as a means of determining absorbed dose from electromagnetic field exposures in phantoms, i.e., the eye and the skull. 4) Provide nuclear instrumentation such as the development and evaluation of the suitability thermoluminescent dosimetry for environmental radiation surveillance. 5) Theoretical solution of plane wave interaction with a finite slab geometry for various complex permittivities and thermal properties. 6) Begin development of an electric field probe for direct measurement of field strength in the phantom system.

In order to formulate meaningful population exposure standards for electromagnetic radiation, it is essential that current background be established. A means of interpreting these values will then provide a baseline for biological effects studies as well as future exposure measurements. Since standards are based on the evaluation of the dose- effect relationships, it is imperative that the biological effects research be derived from a sound dose measurements program.

Engineering-physics techniques will be applied in the area of electromagnetic radiation measurement. The range of project activity will encompass areas of applied dosimetry, theory, calibration, and facility support. Specifically, methods will be developed and evaluated from fundamental bases, keeping in mind the theoretical limitations and the engineering approximations involved. Estimates of uncertainty will be established. This program will produce a description of a unique controlled environment exposure facility, theoretical and experimental exposure considerations from RF pollution, a method for using liquid crystals for nonionizing radiation dosimetry in biological systems, and a quantitative assessment of errors and artifacts involved in using TLD for environmental surveillance of nuclear facilities.

5.0855, RECOVERY PROCESSES IN AN AMEBOID CELL
J.B. LITTLE, Harvard University, School of Public Health, *Boston, Massachusetts* 02115

The basic objective of this research program is to gain further understanding of the nature and importance of intracellular recovery or repair processes in irradiated cells, particularly as they may affect radiosensitivity at lower doses. The cell we are studying is an ameboid cell belonging to the genus Hartmannella of small free-living amoebae. The gamma-ray survival curve for these cells shows a very prominent shoulder compared to the slope of its linear portion, yielding a threshold dose of 600,000 rads, but a D-subzero of only 27,000 rads. The ultraviolet irradiation survival curve, on the other hand, is nearly a simple exponential function of dose with a very small shoulder. Split-dose experiments suggest that these cells possess a highly effecient repair mechanism for gamma radiation damage; the effects of 500,000 rads are largely repaired within 6 hours after exposure, and by 24 hours the cells respond as if they had received no prior irradiation. Current experiments are designed to further examine the kinetics of the recovery from radiation damage, and to determine more precisely the nature of the repair process. The inter-relations between the effects of ultraviolet and gamma radiation will also be studied.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0856, ABSORBED DOSE DUE TO INTERNAL RADIATION EMITTERS
G.L. BROWNELL, Mass. General Hospital, *Boston, Massachusetts* 02114

The aim of this project is to investigate advanced methods of dose calculation and to compare the results of these calculations with experimental observations. Gamma-ray dose calculations are based principally on Monte Carlo methods of gamma-ray diffusion. Several existing programs will be extended to permit calculation of gamma-ray dose for a wide variety of geometrical conditions and for inhomogeneous media and for interfaces.

The development of a special Monte Carlo program providing spectral information will permit a wider range of application than has been possible in the past.

The experimental verification of dose calculation methods has been largely lacking in the past. Experiments will be performed to confirm Monte Carlo calculations of dose in various configurations including nonhomogeneous media and media containing interfaces.

5.0857, NEUTRON ACTIVATION ANALYSIS
J.C. CARDARELLI, U.S. Veterans Administration, Hospital, *Boston, Massachusetts* 02130

We have been continuing our activation analysis research in two directions since our last report. Because of the closing of the nuclear reactor at the Army Materials and Research Center in Watertown, Mass., we have been forced to use the nuclear reactor facility at M.I.T. This nuclear reactor offers a higher neutron flux enabling us to determine more sensitive amounts of Iodine-128. Hence, in conjunction with our investigation of insulin tagged compounds with stable iodine we are now able to investigate stable iodinated compounds of serum such as T-3 (thyroxine) which had been studied in our laboratory for many years by chemical means. This nuclear activation analysis technique affords us a great luxury due to its hypersensitivity as compared to the ordinary chemical determinations.

Preliminary studies of thyroxine measurements show that this method of analysis is feasible, however work is being done to improve and facilitate the method.

5.0858, MANUAL OF ACCELERATOR RADIATION PROTECTION
J.G. MARTIN, U.S. Army, Natick Laboratories, *Natick, Massachusetts*

Technical Objective: There exists within the Army a severe need for the establishment of accurate and comprehensive guidelines for the safe operation of accelerator facilities. The Army is not unique in this need, state after state has been enacting legislation regulating the uses of radiation-producing machinery. Even with these new laws, the ability of personnel to find easily usable guidelines is severely lacking. Capabilities exist at NLABS to produce a manual which would provide guidelines and promote radiation protection throughout the nation.

5.0859, COUNTER MEASURE STUDIES AGAINST VULNERABILITY OF PERSONNEL AND MATERIALS TO TACTICAL LASER IRRADIATION
J.A. SOUSA, U.S. Army, Natick Laboratories, *Natick, Massachusetts*

5. RADIATION

Technical Objective: Evaluate tunable laser devices for possible surveillance of army materials from natural background. Analyze the mechanisms of spontaneous and stimulated emission in dye systems and to investigate the possibilities of quenching such mechanisms. Dyes that luminesce in the ultraviolet or near-infrared region and that remain non-luminescent to the observer in visible light will be investigated.

5.0860, TOOTH COLLECTION FOR RADIOACTIVE NUCLIDE STUDY

H.L. ROSENTHAL, Washington University, School of Dentistry, *Saint Louis, Missouri* 63130

Deciduous teeth of children born between 1948 and the present are being collected for measurements of strontium-90 content. Correlations between sound and carious teeth, teeth of children who were breast fed versus teeth of children who were bottle fed, and teeth of children living in other areas of the world are being studied. Additional studies of strontium-90 content of human fetal bone and tooth buds are in progress as are studies of nuclide content of permanent teeth (bicuspids).

The data obtained are being correlated with the dietary strontium- 90 burden of the mother and the children. These correlations show a linear relationship between tooth strontium-90 and dietary nuclide burden. With due regard to discrimination factors and time of tooth formation, the equations make it possible to predict the strontium-90 burden of children from the nuclide concentration of commercial milk sources.

5.0861, RADIATION DOSIMETRY

A.J. BLOTCKY, U.S. Veterans Administration, Hospital, *Omaha, Nebraska* 68105

Techniques for the utilization of phosphate glass rods in determining gamma dosimetry in an 18-KW Triga reactor have been developed and results compare favorably with thermoluminescent dosimetry. Fast and thermal flux measurements are obtained by the use of threshold detectors, making it necessary to use separate detectors to simultaneously measure the gamma and neutron dose in the reactor.

Since the Yakota glass used in the glass rods contains 33.5 weight % phosphorous, the reaction P-31 (n, alpha) P-32 can be used to determine the thermal neutron dose and P-31 (n, p) Si-31 to determine the fast neutron dose above 2.5 Mev. Thus, by reading the gamma dose on the fluorometer and counting the activity of the P-32 and Si-31 on a radiation counter, the various components of the radiation can be determined with one detector.

Recent work by E. Piesch (1) has indicated that the measurement of the Cerenkov effect of induced beta radiation by a liquid scintillation counter offers advantages over other methods of detection since the measuring geometry is better, and the background lower thereby enabling the detection of lower flux. An additional advantage of utilizing the Cerenkov effect for the detection of gross beta radioactivity is that emitters having energies below 1 Mev are not measured and consequently the beta activity of P-32 (E max equals 1.7 Mev) and Si-31 (E max - 1.5 Mev) can be determined without any influence by low energy spurious radiation components.

The use of the Cerenkov effect for counting will be investigated and a procedure developed for measuring the alpha, thermal and fast neutron dose with one director.

5.0862, HIGH ALTITUDE RADIATION ENVIRONMENT STUDY

M. BARON, U.S. Air Force, Weapons Laboratory, *Albuquerque, New Mexico* 87117 (000578)

This project is being conducted to measure the radiation environment at SST cruising altitudes and at various latitudes using active and passive dosimetry and radiation spectral measuring instrumentation. The information obtained will be used to assess the biological effects of ionizing radiation in the SST and to develop realistic standards for radiation exposure and procedures for SST operations in order to provide maximum protection to the air crews and the flying population.

The 4 HARIS units procured under contract FS-65-24 are employed in RB-57F aircraft which are currently operating from both Kirtland AFB, N.M. and Eielson AFB, Alaska. Radiation measurements are also made at lower altitudes but at high latitudes employing other jet aircraft. Alert/Scramble missions were authorized in 1968 for recording data for measuring solar protons at high altitude. Data are being reduced and analyzed by means of a computer program at Kirtland AFB. The results of these measurements will be used by radiation biologists in order to advise the Federal Air Surgeon on radiation biology measures to be taken in case of critical dose levels. A Standing Committee on Radiation Biology Aspects of the SST was established in 1967 which provides guidance in conducting the HARIS project and advice to the FAA on the application of the results obtained. Data were obtained from about 60 flights. An aircraft is now being operated out of Alaska on a special assignment to insure an improved opportunity to obtain information at polar latitudes during solar flare conditions. NASA is cooperating in funding for this effort. Data collection should be completed by 1970.

5.0864, CALIBRATION OF RESPIRABLE DUST SAMPLERS FOR INHALATION HAZARD EVALUATION

H.J. ETTINGER, U.S. Atomic Energy Commission, Health Division, *Los Alamos, New Mexico* 87544 (W-7405-ENG-36)

Properly calibrated 'respirable' dust samplers are required to evaluate the hazard from inhalation of radioactive or toxic particles. Depending on aerodynamic size, particles will either be trapped in the upper respiratory tract and rapidly clear from the body, or deposit in the lower respiratory tract and undergo long term body retention. While several standards have been adopted defining particle sizes which constitute an inhalation hazard, air

samplers measuring this hazard had not been adequately calibrated. Several two-stage air samplers designed to separate particulates into one fraction representing material trapped in man's upper respiratory tract, and a second fraction which penetrates to man's lower respiratory tract, were calibrated using monodisperse test aerosols in the size range of 2 to 10 microns.

Results: Calibration data for the two cyclone samplers used to estimate 'respirable dust' show that initially recommended operating procedures will underestimate potential inhalation hazards. Proper sampling flow rates should be approximately one half those recommended by previous calibrations based on microscopic particle size.

5.0865, BASAL METABOLIC RATES AND EXCRETION OF RADIONUCLIDES

J.E. FURCHNER, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

In the absence of data derived from humans, data derived from experimental animals have been used in this laboratory to estimate radiation protection guides. Such estimates are derived from extrapolations based on the assumption that the excretion rates of the elements in question are related to the basal metabolic rates of the various species. Because basal metabolic rates are found to be a power function of body weight, extrapolations from the retention-excretion parameters of experimental animals are made on the basis of body weight. The purpose of this project is to determine if artificially-induced alterations in basal metabolic rates (e.g., oxygen consumption) are accompanied by proportionate alterations in the excretion rates of test radionuclides.

Results to Date: Triiodothyronine administered via the drinking water to Sprague-Dawley rats, RF mice, and African white-tailed rats had no perceptible effect on the exretion rate of cesium-137.

SUPPORTED BY U.S. Atomic Energy Commission

5.0866, FALLOUT CESIUM-137 IN A NORMAL POPULATION

J.E. FURCHNER, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

Measurement of temporal changes in cesium-137 body burdens of local control subjects is continuing on a weekly and monthly schedule with a total of 40 subjects. Data for this project have been collected without interruption since 1956. Radiation doses are calculated for the sample based on the measured cesium-137 burdens for monthly or quarterly increments. The data are used to establish a relation between dietary levels and body burdens and to test models for the time-course of activity in a normal population. Whole-body radioactivity measurements are made in a large-volume liquid scintillation counter of almost 4 pi geometry. Gamma-ray spectrometry is used occasionally to detect the presence or to confirm the absence of gamma-emitting isotopes other than cesium-137 and naturally-occurring potassium-40.

Results: A parent-daughter model gave a reasonably accurate description of cesium-137 body burdens during the period of rapid increase, the 1964 peak, and the subsequent decrease. The model needs further modification to describe a relatively stable body burden of approximately 2 to 3 nCi in the measured population.

SUPPORTED BY U.S. Atomic Energy Commission

5.0867, CHARACTERISTICS OF A WITHIN-STRAIN RADIATION RESISTANCE FACTOR

J F. SPALDING, Univ. of California, Los Alamos Scientific Lab., *Los Alamos, New Mexico* (W-7405-ENG-36)

The relationship between radiation resistance and other phenotypic and genotypic traits in the mammal is of considerable interest and is extremely useful to an understanding of the mechanisms involved in radiation injury and repair kinetics. A within-strain radiation resistance factor has been isolated and preserved in an RFM colony of mice. Investigations are being carried out to determine the possible relationship between radioresistance and activity, life span, and reproductive efficiency. The genetic inheritance of this radiation resistance factor is also under study.

Results: The factor for radiation resistance has been shown to be effective at the bone marrow level, dominant to sensitivity, consistent with a single gene hypothesis, and inversely related to voluntary activity.

SUPPORTED BY U.S. Atomic Energy Commission

5.0868, THE CYCLING OF MICRONUTRIENTS IN GEOCHEMICAL AND BIOLOGICAL SYSTEMS

W.H. ALLAWAY, State University of New York, U.S.D.A. Soil & Wa. Cons. Div., *Ithaca, New York* 14850 (SWCW22-AA-4)

OBJECTIVE: Identify and characterize the processes involved in the movement of trace elements from soils to plants to animals, to ascertain the factors influencing the rate and pathways of these movements and to evaluate procedures for their control.

APPROACH: The chemical forms of trace elements in rocks and soils are determined. Factors affecting the uptake of trace elements by plants and the translocation, chemical forms and metabolism of these elements within plants are studied. The absorption and excretion by animals of different forms of trace elements in the diet are measured, and the extent and pathways of recycling of excreted trace elements through soils and water back into biological systems are evaluated.

PROGRESS. A survey was made of regional variations in the zinc content of plant tissue with the objective of evaluating the possibility of endemic differences of Zn in the human population. There is a growing body of evidence that the supply of Zn to the human population is marginal for optimum rates of wound healing. The survey of Zn in plants revealed a small but distinct regional pattern of variation in the Zn content of plant tissue. In general, the Great Plains and the South had the lowest level, 25 to 33 ppm Zn, in alfalfa. This is compared with 33 to 45 ppm Zn in alfalfa from the Northeast and North Central States. In an earlier study, a somewhat similar geographic pattern in the concentration of Zn in the blood of residents of different parts of the U.S. was noted - i.e., people residing in the Northeastern U.S. had generally higher levels of blood Zn than did residents of the Southeast. This suggests that even small differences in levels of Zn in plants from different regions may possibly be reflected in differences in the level of Zn in human diets. Experiments to test the value of dietary selenium (Se) in the protection of intact animals from damage due to free radicals generated by ionizing radiation have been conducted in cooperation with the Cornell Animal Science Department. Although radiation protective effects of Se noted to date have not been pronounced, they do indicate that more definitive effects may become evident in experiments that provide a sensitive measure of radiation damage.

5.0869, THEORETICAL ASPECTS OF MICRODOSIMETRY

A.M. KELLERER, Columbia University, School of Medicine, *New York, New York* 10032 (AT-(30-1)-2740)

The theory of energy straggling which is central in the analysis of microdosimetric functions has been further developed. A new computer program uses Fourier-analysis to derive straggling distributions for arbitrary absorber thickness from a distribution for a given thickness. The program can also derive the underlying collision spectrum if a straggling distribution is known with sufficient accuracy. Fourier- analysis is also used in a technique to derive LET-spectra from pulse height spectra obtained in proportional counters. The problem of chord- length distributions resulting from the random traversal of convex bodies has been solved by a computer program which is applicable to arbitrary shapes of the traversed body and to arbitrary angular distributions of fluence. A systematic listing of distributions for circular and square cylinders and of their moments is now available. The study of the distribution of segment lengths in a body has been extended to tracks which are neither straight nor infinite, and it has been possible to generalize the so-called theorem of CAUCHY on the mean traversal length to the general case. Methods of pattern

analysis are presently being applied to the problem of track structure. These studies indicate that probability distributions of the distance between collision events may offer an alternative to the microdosimetric functions. Part 3 of 5.

5.0870, DOSIMETRY OF IONIZING RADIATION, RADIATION BIOPHYSICS AND RADIOBIOLOGY
H.H. ROSSI, Columbia University, School of Medicine, *New York, New York* 10032 (AT-(30-1)-2740)

It is the primary objective to establish the connection between energy absorption and biological effect. Theoretical research includes stochastic theory, reaction kinetics and the development of biophysical models; physics research includes dosimetry, microdosimetry and radiological physics, including experimental and theoretical research on electron diffusion in gas mixtures and performance characteristics of proportional counters. The biophysical research is concerned with radiation effects on opacification of the murine lens, aberrations in Tradescantia stem hairs, and genetic effects in both Drosophila and Zea mays. Biological research includes effects of radiation on mammalian cells in tissue culture, including effects on resting phase cells and continuous irradiation of cultures; and radioembryology of the mouse. A Van de Graaff accelerator is being developed for this research with appropriate modifications and the initiation of general dosimetry systems. Other radiation sources employed in this research include X- rays, gamma rays, alpha rays, Cf-252 sources, and heavy ions.

SUPPORTED BY U.S. Atomic Energy Commission

5.0871, RADIOACTIVITY STUDIES
M. EISENBUD, New York University, School of Medicine, *New York, New York* 10016 (AT(30-1))

This is a continuation of a program of research that has been underway for several years. The studies involve measurement of naturally occurring radionuclides in the environment and human tissues and the investigation of the transport of the heavy radionuclides following ingestion or inhalation by experimental animals. The accumulation of stable elements in bone is also being studied under this contract.

Results: The results to date are summarized in the September, 1969 progress report number NYO-3086-8.

SUPPORTED BY U.S. Atomic Energy Commission

5.0872, BIOLOGICAL AND CLINICAL DOSIMETRY
J.S. LAUGHLIN, Sloan Kett. Inst. Cancer Res., *New York, New York* (AT(30-1))

The further dosimetric evaluation of neutron beams produced by a small cyclotron for radiobiological and clinical applications is proposed. This will include the continued development of a tissue equivalent calorimeter and its application to the calibration of other dosimeters as well as the determination of the neutron spectra and Linear Energy Transfer distributions for a variety of reactions.

Ultra-high dose rate dosimetry studies will be continued using the 30 nanosecond and dual channel 3 nanosecond 600 KeV field emission pulsed electron sources. They will be used to study dose rate dependence of thermoluminescent dosimeter materials in the range from less than 10 to the 11th power rads/sec to greater than 10 to the 13th power rads/sec. Monitoring techniques for the 3 nanosecond pulse source will be extended to measure beam energy fluctuations.

Arrays of lithium drifted germanium diodes will be constructed in an orthogonal strip geometry and tested for use in a semiconductor gamma camera.

The energy spectrum of fast neutrons generated by a cyclotron will be obtained from measurements of secondary protons using a lithium drifted diode.

Results: Preliminary dosimetry evaluation of a variety of neutron spectra produced by a small cyclotron for dosimetric and radiobiological studies has been accomplished utilizing tissue equivalent ion chambers, thermoluminescent dosimeters and activation techniques. Dose rates obtainable are adequate for absorbed dose microcalorimetry and radiobiology research.

The current transformer monitor system developed for the 30 nanosecond electron source has been improved significantly.

The use of specially constructed miniature in vivo silicon diode probes will be extend to radiation dose measurements in the urethra and nasopharynx.

A monitor system for the 3 nanosecond field emission electron source has been developed using a beam current pick-up loop. The correlation between this monitor and a Faraday cup has been demonstrated to an accuracy of plus or minus 1 percent. drifting of germanium diode have been completed. These include construction of conventional and special cryogenics. Specially constructed miniature silicon diode probes have been employed successfully in vivo as radiation dose monitors.

5.0873, RADIATION DOSE FROM DIAGNOSTIC ISOTOPE PROCEDURES
E.M. SMITH, Soc. of Nuclear Medicine, *New York, New York* 10017

The objective of the Medical Internal Radiation Dose Committee is to estimate the absorbed dose received by patients from various radiopharmaceuticals used in nuclear medicine. To date the Committee has published three separate Supplements to the Journal of Nuclear Medicine. These Supplements have contained pamphlets on the formalism for absorbed dose calculations, energy build-up factors, absorbed fractions for photon dosimetry including those for simple geometrical shapes and those for various organs of a heterogeneous phantom. In addition, the nuclear and decay scheme data for 24 radionuclides of medical importance was published. A fourth Supplement to be published in February, 1970 contains the decay scheme and nuclear parameters for thirty additional radionuclides. During the early part of 1970 a Supplement was to be published containing absorbed dose estimates to humans from mercury-197 and mercury-203 as labeled chlormerodrin and selenium-75, as l-selenomethionine and technetium-99 as pertechnetate ion, various isotopes of iodine administered as the iodide ion, as well as several other radiopharmaceuticals. Additional reports on absorbed fraction data for both photons and monoenergetic electrons as well as for the beta spectra for various radionuclides will be published. The committee is working on the collection of biological data for many different radiopharmaceuticals, and the absorbed dose to humans from each of these radiopharmaceuticals will appear in separate pamphlets. The work of the MIRD committee is open ended, and will continue as long as new radiopharmaceuticals are developed.

5.0874, RELATIONSHIP BETWEEN THE PHYSICAL PROPERTIES OF INHALED AEROSOLS AND RESPIRATORY DEPOSITION
A.J. BRESLIN, U.S. Atomic Energy Commission, Health & Safety Laboratory, *New York, New York* 10014

Measurements of respiratory deposition as a function of particle size and other variables are being made both under controlled conditions in the laboratory and in occupational environments. These measurements are obtained to check the validity of current lung models and to extend the range of empirical data.

Predictions of the fate of inhaled radioactive particles in the respiratory system and calculations of internal dose depend on specific knowledge of the influence of the physical properties of particles on deposition. Moreover, quantitative knowledge of these influences is needed to design field instruments that accurately measure the hazard of occupational dust exposures.

The development of methods for generating homogeneous aerosols in sizes from 0.1 mu to 10 mu and the availability of reliable methods for the rapid measurement of the aerosols makes it feasible to perform deposition studies simply and efficiently. Complementary measurements in the actual work atmospheres provide a means of confirming laboratory findings.

Results: Respiratory deposition of radon daughters has been measured in the laboratory and in uranium mines. A pilot study proved the feasibility of measuring respiratory deposition and excretion of inhaled uranium dust.

SUPPORTED BY U.S. Atomic Energy Commission

5.0875, CHARACTERISTICS OF URANIUM MINE ATMOSPHERES
A.J. BRESLIN, U.S. Atomic Energy Commission, Health & Safety Laboratory, *New York, New York* 10014

The radiological characteristics of mine air and the physical properties of radon daughters and other aerosols are being measured in uranium mines to provide more reliable procedures for monitoring occupational exposures, improved monitoring instrumentation, and more accurate estimates of internal dose received by miners. Radiological characteristics under investigation include the magnitude and variation of radon gas concentration, working level, radon daughter ratio and ore dust concentration. Aerosol properties being measured are the particle size distribution of radon daughters and condensation nuclei, the unattached fraction of radon daughters, and the relationship between unattached fraction and the concentration of condensation nuclei. Instrumentation of several types has been developed to achieve convenient and reliable measurements in mine environments. Measurements are performed in representative mines in each of several geological formations to cover a variety of mining conditions.

Results: Radiological characteristics of nine uranium mines were intensively surveyed. The particle size distribution of radon daughters in a uranium mine was reported.

SUPPORTED BY U.S. Atomic Energy Commission

5.0876, INSTRUMENTATION AND METHODS FOR THE MEASUREMENT OF RADIOACTIVE AIR CONTAMINANTS
A.J. BRESLIN, U.S. Atomic Energy Commission, Health & Safety Laboratory, *New York, New York* 10014

Instruments and methods for the measurement of radioactive air contaminants are developed when needed for specific research objectives at the Health and Safety Laboratory or for more general applications in the AEC program. Early products of this effort were portable air sampling instruments of various types for use in industrial hygiene surveys at feed materials plants. Present efforts are focused mainly on instrumentation for use in uranium mines. A simple field method for the measurement of radon gas (two-filter method) was developed and has been used extensively in uranium mine studies. For determination of the particle size of radon daughters, several compact, highly efficient diffusion batteries were developed and are presently used both in the laboratory and in the field. In another approach to measuring the particle size of radon daughters, a differential diffusion filter is under development, consisting of a cylinder containing a series of identical filters, all operating in the diffusion regime. The particle size distribution can be obtained by a mathematical analysis of fractional penetration through the successive filters.

Results: Several radon dosimeters developed by other groups for monitoring the exposures of uranium miners have been evaluated with respect to accuracy and durability.

SUPPORTED BY U.S. Atomic Energy Commission

5.0877, MONITORING OCCUPATIONAL EXPOSURES TO RADIOACTIVE AIR CONTAMINANTS
A.J. BRESLIN, U.S. Atomic Energy Commission, Health & Safety Laboratory, *New York, New York* 10014

Increased accuracy and efficiency in measurements of occupational exposures to air contaminants is being sought through investigations of the temporal and spatial variation of atmospheric concentrations, measurements of the physical properties of radioactive air contaminants, and the evaluation of monitoring instruments. In particular, the physical properties (size, density, charge) of the contaminant influence the site and magnitude of internal dose. A systematic study of concentration variation in typical occupational environments is planned to derive relationships of sampling frequency and location to the error in an estimate of exposure. From this information, monitoring procedures can be devised for specific circumstances from objective criteria.

Measurements of particle size and other properties of air contaminants in work environments can be used to check the validity of assumptions in MPC calculations.

The reliability, accuracy and precision of available sampling instrumentation are evaluated in the laboratory and actual occupational environments.

Results: Several papers on the influence of instrumental error and of environmental variance on the accuracy of exposure monitoring were published.

SUPPORTED BY U.S. Atomic Energy Commission

5.0878, ANALYTICAL INSTRUMENTATION FOR MEASUREMENT OF ENVIRONMENTAL SAMPLES
R.T. GRAVESON, U.S. Atomic Energy Commission, Health & Safety Laboratory, *New York, New York* 10014

The identification and measurement of radionuclides in the environment requires specialized equipment for sample analysis. Since the levels of activity normally are low, the instrumentation must have unusually high sensitivity and low background.

Standard high resolution spectroscopy has been established for qualitative and quantitative isotopic identification, but special shielding and guard logic techniques are being developed to achieve low background. Thin detectors, anti-Compton guard detectors, and dual detectors for Compton acceptance are being developed to minimize the obscuring effects of higher energy interactions.

Developmental activities include the application of scintillation, solid state, and gas proportional detectors to the measurement of trace radioactive elements in soil, air, and biological samples.

Results: Two lithium drifted germanium detectors have been installed in graded shielding for low background operation. On one unit, a large scintillation anticoincidence guard rejects Compton induced events. This increases the usual 33 to 1 Peak-to-Compton ratio of the coaxial detector to 195 to 1. Both units have been interfaced to a small digital computer for data acquisition and display, and for output which is compatible with computer center format.

SUPPORTED BY U.S. Atomic Energy Commission

5.0879, INSTRUMENTATION FOR FIELD OPERATIONS IN RADIOLOGICAL PHYSICS
R.T. GRAVESON, U.S. Atomic Energy Commission, Health & Safety Laboratory, *New York, New York* 10014

Environmental radiation measurements require instrumentation which will operate reliably under difficult field conditions. The project objectives are to develop experimental equipment for determining the characteristics of penetrating radiation and of air-borne particulates.

The short half-life of radon daughter products requires that the measurements be carried out in the field. Personal air samplers, alpha counting systems, and aerosol particle size separators are being designed for experiments in characterizing the atmosphere and exposures in uranium mines.

Detectors for cosmic-ray and environmental gamma flux analysis also are provided. As the measurement systems become more complex, extensive data must be recorded and battery-operated magnetic tape storage equipment is being developed to provide simultaneous recording of time- correlated information. Also, this technique will use computer compatible methods and allow simplified data reduction on return to the laboratory.

Results: A miniaturized field scaler and a battery-operated alpha spectrometer using a semi-conductor detector have been developed for use in uranium mine surveys. Cosmic-ray experiments have been provided with a group of instruments developed for operation on high altitude balloon flights. These include a highly stable electrometer for the measurement of ionization chamber currents and a charged particle detector system. The data is recorded on self-synchronized impulse driven strip-chart recorders developed for this application.

5.0880, NUCLEONIC TRANSPORT STUDIES
J.E. MCLAUGHLIN, U.S. Atomic Energy Commission, Health & Safety Laboratory, *New York, New York* 10014

5. RADIATION

We develop calculational and measurement techniques for nucleonic cascades in matter to aid in radiation shield design and in determining the response of detectors, the propagation of cosmic-rays in the atmosphere, and depth-dose curves in tissue.

Analytical solutions to the Boltzman equation are obtained by the straight-ahead approximation at high-energies, and by polynomial approximations at low energies. In addition, the use of the LASL discrete ordinates code (DTF-IV) is planned to study nucleonic cascades over a very wide range of energies (10 to the minus 2nd power to 10 to the 13th power eV). Neutron yield and shield transmission measurements are made to provide benchmark data.

Results: Calculations of ionization from cosmic-rays have been compared with balloon-measurements over a wide range of elevations with good results. The components contributing to cosmic-rays at sea-level have been computed and will be published.

Two-dimensional nucleonic cascade calculations have been carried out for comparison with measurements made at the Stanford Linear Accelerator of the cascade in tin. Extension to depth dose curves in tissue from hadrons at cosmic-ray energies is planned.

SUPPORTED BY U.S. Atomic Energy Commission

5.0881, ENVIRONMENTAL RADIATION STUDIES

J.E. MCLAUGHLIN, U.S. Atomic Energy Commission, Health & Safety Laboratory, *New York, New York* 10014

We investigate the properties of ionizing radiation in the environment that are significant for human population exposure and develop techniques for quantitative analyses of complex low-level radiation fields.

Experiments require the measurement of cosmic-ray ionization, particle flux, and dose rate in the atmosphere; thermoluminescent dosimetry for determining the exposure of individuals to environmental gamma radiation; and the study of the distribution of naturally occurring and artificially-produced radionuclides in the environment. The related transport calculations are important in the data interpretation.

Future environmental radiation studies include: (1) a correlation of all experimental and calculational results into a comprehensive analysis of the significant properties of cosmic radiation within the atmosphere, (2) field studies of population exposure to environmental radiation in selected areas, (3) development of techniques for the detection and quantitative analysis of levels of radioactivity around nuclear facilities.

Results: Balloon flights have been made with ionization chambers, and an ionization profile in the atmosphere has been obtained which is in general agreement with our nucleonic cascade calculations. Monte Carlo calculations of the electromagnetic cascade have provided quantitative estimates of wall perturbations in these chambers.

Procedures for measuring personnel doses with LiF dosimeters down to 1.5 mR have been developed, and several such dosimeters have been tested.

SUPPORTED BY U.S. Atomic Energy Commission

5.0882, GLOBAL DISTRIBUTION AND INVENTORY OF SR-90 AND OTHER FISSION PRODUCTS

H.L. VOLCHOK, U.S. Atomic Energy Commission, Health & Safety Laboratory, *New York, New York* 10014

Since 1959, about 140 stations have been collecting monthly precipitation which is analyzed for Sr-90 and Sr-89. The collectors are either high-walled stainless steel pots or funnel-ion exchange columns. The global fallout rate distribution of radiostrontium and deposit increments, for assessing the fallout inventory, are derived from this project.

Deposition of Pu-238 from the SNAP-9A satellite re-entry in April 1964 is measured monthly in New York City, Melbourne, Seattle and Rio de Janeiro.

Soil sampling is carried out near nuclear installations when there is a need to inventory the integrated amount of a specific radionuclide that may have been released either routinely or accidently.

Results: In the first half of 1969, about 150 kilocuries of Sr-90 were deposited on the earth's surface, about 54% of which was in the northern hemisphere. The cumulative burden of Sr-90 in the northern hemisphere decreased as radioactive decay continued to exceed the fallout rate; in June 1969 the deposit was about 9.5 MCi. In the southern hemisphere the deposit was gradually increased, reaching 2.7 MCi in June.

5.0883, DEVELOPMENT STUDIES IN LOW LEVEL RADIOCHEMICAL ANALYSES AND TRACE STABLE ELEMENTS IN BIOLOGICAL AND ENVIRONMENTAL MATERIALS

G.A. WELFORD, U.S. Atomic Energy Commission, Health & Safety Laboratory, *New York, New York* 10014

This program develops radiochemical, radiometric, and other methods of analysis to determine the levels of radionuclides and stable elements in man and his environment. This program is required to increase sensitivity, accuracy, and precision of existing methods and provide methods where they do not exist. This is accomplished by investigating and applying both classical and new techniques to low level radiochemical and trace element analysis.

Newer analytical techniques and instrumentation are periodically investigated for our application. Presently, some of these are atomic absorption spectrophotometry, ion exchange in mixed solvent systems, gas chromatography, paper and electro chromatography, X-ray spectrometry, Cerenkov counting methods, and stable element determination using radio- reagents.

Results: The stable alkaline earth metals have been determined sequentially in a variety of biological matrices. A method for leaching and determination of small amounts of the plutonium isotopes in kilogram quantities of soil has been developed. Stable lead has been documented in air and biological material in New York City.

Carbon-14 and tritium (tritiated water) have been documented in New York City air. A method for gas counting using a thin plastic beta phosphor has been developed. High resolution Ge(Li) gamma ray spectrometer systems, recently installed, confirmed the introduction of cobalt-57 and cobalt-58 into the stratosphere by foreign nuclear tests.

5.0884, CHEMICAL DOSIMETRY

H.L. ANDREWS, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT(30-1)49)

Objective: To determine the usefulness of some organic halogen compounds as chemical dosimeters for ionizing radiation and for microwaves.

Scientific Background: Organic halogen compounds are known to be sensitive to radiolysis by ionizing radiations. The usual reaction leads to the production of hydrocholoric acid with a resulting sharp change in the electrical properties of the aqueous solution. Indicators have been incorporated into the solution to give a visual indication of the pH change and hence of the radiation dose. The addition of a gelling agent permits a three-dimensional visualization of a radiation beam. Previous work with chloral hydrate-methyl rad-agar systems showed promise but lacked the desired sensitivity.

Procedure: To determine the capabilities of the system it is necessary to optimize the proportions of the three components after having selected the most suitable indicator and gelling agent. A limited number of indicators were selected and compounded with a series of agents such as styrene and acrylamide which gel by polymerization. Results were uniformly disappointing because the radiation sensitivity of these polymers was poorer than the agar gels previously used. It seems unprofitable to pursue this work further. It remains to explore the possibility of using the organic halogens as a detector of microwave radiation. A segment of a toroid is filled with the solution and the circuit is completed with a diode rectifier. A D.C. current will be produced and this will produce electrolytic products in an amount proportional to the integrated field intensity.

RESULTS: The results of the gel systems have been disappointing. Any gelling agent tried reduces the system sensitivity to an unacceptable level. The original agar gel appears to be the most satisfactory, in spite of its variable characteristics from batch to batch.

Suitable electrode materials have been found for the microwave dosimeter, and dose-yield measurements are in progress.

5.0886, CONTROL OF ION CONTENT OF CELLS

G.G. BERG, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT(30-1)49)

OBJECTIVE: This study is aimed at understanding the 'molecular pumps' which transport sodium, calcium, and strontium out of living cells and potassium and cesium into cells, and are directly involved in handling a number of ions that may cause damage either by radioactivity (cesium-137, strontium-90) or by chemical toxicity (lead, beryllium). Knowledge of the performance parameters of these pumps contributes to our ability to predict the accumulation of environmental contaminants by all kinds of living organisms. SCOPE OF THE STUDY: (1) Control of monovalent cations: The red cell ghost is used as a model system for a study of uptake of potassium by cells. Potassium transport in many-celled organisms may be regulated through endogenous production of selective pump-blocking inhibitors, and traces of such inhibitors have been discovered in human white cells in this laboratory (Weed, et al., 1963). We will determine the properties of the white cell factor and the mechanism of inhibition of the sodium-potassium pump by this factor. (2) Control of divalent cations: The red cell ghost and the 'inverted' ghost are used as model systems for a study of active transport of calcium out of the cytoplasm. Questions under consideration are (a) which ATPase enzyme is part of the pump, (b) what is the selectivity of the pump for calcium over strontium, and (c) what is the action of lead on the pump. (3) Field study of cation transport: Organisms living in Springville Reservoir in West Valley, New York are continuously exposed to significant concentrations of cesium-137 and strontium-90. We will collect and classify exposed plants and animals (especially phytoplankton and zooplankton) and measure the levels of potassium, cesium, calcium, strontium, and their isotopes in relation to ambient concentrations. First problem is to measure cesium/potassium and strontium/calcium ratios in various species (scintillation counting, sodium iodide well counting, atomic absorption spectrophotometry).

Results: A study of mechanisms of precipitation of lead salts in lead-ATP systems was brought to completion. A white cell factor with glycoside-like properties was discovered in human blood. 'Sodium pump' and 'calcium pump' ATPase were studied in mammlian cells and a functional zinc as a tissue-specific pump inhibitor was demonstrated.

5.0887, AN INVESTIGATION INTO THE PHARMACOLOGICAL PROPERTIES OF ANTI-IRRADIATION DRUGS

V. DISTEFANO, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT)

The broad objectives of this research have been to develop antiradiation drugs which are as free as possible from undesirable side effects. Attention has been given to mechanisms of action on whole animal, organ, organelle and enzymatic levels. Particular emphasis has been placed on the effects of a prototype antiradiation compound, mercaptoethylguanidine (MEG), on catecholamine biosynthesis, storage and release. Under the appropriate conditions, the stimulation by MEG of catecholamine release and synthesis appears to account for a significant increase in the radiation protectivity of this agent. Preliminary studies have shown that MEG inhibits the conversion of the precursor dopamine (DA) to norepinephrine (NE) in isolated adrenal catecholamine storage granules. On the other hand, MEG stimulates markedly the formation of NE from DA when preparations of dopamine beta oxidase (DBO) are used. These studies will be extended to include the effects of other protectant thiols related to MEG as well as some of the thioates wich have been shown to be effective in radiation protection. Attempts will also be made to resolve the discrepancy between the effects of MEG on NE synthesis by whole granules and isolated DBO by varying the constitution of the media used in the two systems. The further development of appropriate microanalytical procedures for the determinations of catecholamines and precursors will continue.

Results: Last year it was shown that MEG releases catecholamines from perfused hearts and adrenals; catecholamine biosynthesis is stimulated in the heart. MEG depresses norepinephrine synthesis from dopamine in isolated adrenal chromaffin granules; stimulation of the transformation of dopamine to norepinephrine is observed when dopamine beta oxidase from granules is used. Resolution of this difference will be the the object of work in the coming year.

5.0888, THE MEASUREMENT OF BIOLOGICAL DAMAGE AND ITS RELATIONSHIP TO 'IN-TISSUE' ENERGY ABSORPTION

H.D. MAILLIE, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT(30-1)49)

Techniques for determining the deposition of energy throughout irradiated animals (including humans) must be developed. Current methods are limited to physical techniques. However, such devices do not lend themselves to the measurement of dose in extremely small loci. The hematopoietic centers in the intramedullary spaces of small animals would be representative of such loci. In addition, accidental human exposures have occurred where depth dose distribution is extremely difficult to interpret due to the lack of adequate physical monitoring devices. This project is directed at examining the response of a biological system to graded doses of ionizing radiation. In particular, in small animals exposed to X-irradiation, the intramedullary doses are determined with small thermoluminescent dosimeters in representative carcasses. Live animals of the same species and of approximately the same size are then exposed in a fashion identical to that used for the carcasses and, at an appropriate time following exposure, the status of the hematopoietic system is examined using Fe59 bone uptake. Quantitiative changes in other physiological systems following irradiation will also be examined.

To date, the rat exposed to X-irradiation has been extensively investigated. Other species exposed to X and gamma rays as well as neutrons will be examined in the future.

Results: The uptake of radiation in the bones of irradiated rats decreases with increasing dose following a curve made up of several exponentials. This is probably due to the differences in radiation sensitivity and iron uptake among the various red cell precursors.

Similar types of response have been noted using 80 kVp, 250 KVp and 1000 kVp X-rays. It is felt that, using the Fe59 uptake

method, the dose to each individual bone can be estimated to plus or minus 15 percent.

5.0889, GENERAL STUDIES IN THE TOXICITY OF RADIOELEMENTS
J.N. STANNARD, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT(30-1)49)

This project is aimed primarily at the assembly of biomedical information critical to the setting of and possible revision of maximum permissible body burdens of radioisotopes and the derived concentrations in air and water. Experimental work is being done through other projects at Rochester and elsewhere. It ties closely to the functions of the principal investigator as Chairman of Committee 34 of the National Council on Radiation Protection and Measurements.

Results: This is essentially a new enterprise in its present form. Some effort will still be needed to write up and publish work on the toxicity of radioprotective agents carried out in the past.

5.0890, NAVY ENVIRONMENT--RADIOISOTOPE STUDIES
W.A. MCKINLEY, Rensselaer Polytechnic Inst., Graduate School, *Troy, New York* 12181 (N00014-68-C-0384)

Technical Objective: The research will contribute data and understanding of the Navy environment resulting from radiation. Study of radioisotope decay schemes and the slowing down of electrons in matter will generate solutions to shielding problems.

SUPPORTED BY U.S. Dept. of Defense - Navy

5.0891, INFLUENCE OF RADIATION QUALITY AND DOSE RATE ON EARLY AND LATE EFFECTS IN CELL-RENEWAL SYSTEMS IN THE MAMMAL
J.L. BATEMAN, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

This study is conducted to obtain and evaluate experimental data for the development of theories of radiobiologic action. Quantitative information is collected systematically on suitable biological (cell) systems exposed to graded doses of ionizing radiations of selected quality, whose precise physical characteristics are determined by microdosimetric measurements. Clarification of the functional relation of radiation quality and physical modifying factors is fundamental to these considerations. Specific determination of the macro- and micro- distribution of dose in the intact animal and in organs of interest enable continued evaluation of both early and late mammalian radiation effects on the basis of dose-response relationships established for particular cell populations. Studies may deal with either somatic or genetic effects. Exposures of biological material to monoenergetic fast neutrons have been important in these investigations and were initiated on the 3-Mev Van de Graaff generator in the BNL Physics Department. Further work will utilize the Van de Graaff generator, recently modified for radiobiological studies.

Results: An experiment completed this year avaluated lens radiosensitivity to 250 kVp X-rays versus age at exposure. At three to four months sensitivity was found to be several times that at birth or at twelve months, which closely parallels the findings of several other investigators with radio-lethality.

A second experiment utilizing lens opacification compared split versus single doses at several different total doses. Not only were the single doses more effective than the same dose split at 24 hours, but were approximately equal to half the dose followed at 24 hours by the full dose, suggesting the first exposure may have caused an accumulation of lens epithelial cells in a resistant phase of their cycle.

5.0892, RADIOLOGICAL PHYSICS
J.W. BAUM, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

Interaction of radiation with matter and fundamental dosimetry concepts are investigated. Emphasis is placed on studies which improve our knowledge and understanding of the mechanisms and space and time relations of energy deposition and degradation in irradiated tissue. Studies of dose in sub-cellular sized regions of tissue are used for correlation with available data on biological effects and to further our insights into possible mechanisms of radiobiological damage. Theoretical models relating microdosimetry, LET, and biological effects are being developed in an effort to explain variations of RBE with LET, oxygen tension, dose rate and other factors; to understand mechanisms responsible for radiation induced tumors; and to determine if a threshold dose exists for various effects.

The 3 foot long cylindrical ionization chamber with internal movable probe chamber was used to obtain LET results for He-4 beams of 1, 2, and 3 MeV obtained from the Van de Graaff accelerator. (Results for proton beams of these energies were obtained last year.)

The repair model for cell inactivation by radiation was developed further. It was shown that this model correctly predicts that extrapolation numbers (n) may vary with LET and for suitable ratios of target parameters a minimum n may occur at intermediate values of LET. At very large values of LET the model predicts that n should be greater than or equal to 1.0.

Analysis of pulse height data from a Rossi-type LET spectrometer generally depends on an assumed triangular distribution from mono-LET particles. For sources with large divergence, this assumption is no longer accurate. For example, a point source located on the inside wall of the detector would produce a rectangular pulse-height spectrum. Tests were made to determine the importance of this parameter using Pu- Be neutron sources. Average LET was in error by more than 10% for source to detector distances of less than a few detector diameters.

SUPPORTED BY U.S. Atomic Energy Commission

5.0893, HEALTH PHYSICS
J.W. BAUM, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

Emphasis is placed on the development of new methods of dosimetry for analysis of accelerator radiation fields of complex composition.

The output from a tissue-equivalent (TE) Rossi-type LET spectrometer contains the necessary information for measurement of dose, dose equivalent and quality factor in fields containing mixed types of ionizing radiations. The development of practical portable survey instruments based on a Rossi detector requires elimination of the multichannel analyzer and gas flow system. A simple electronic system was described earlier which satisfactorily replaces the analyzer. The system employs an electrometer and two biased amplifiers to provide pulse weighting for quality factor. Output can be read directly in rad/hr or rem/hr.

Elimination of the gas flow system required studies of contaminates released by the plastic walls of the detector into the counting gas. The principal contaminants found were water vapor and oxygen. For a typical 4 inch diameter detector filled to 20 mm Hg pressure with TE gas, we have demonstrated that these effects can be minimized by (a) employing a few grams of P_2O_5 desiccant to continuously remove water vapor and (b) thoroughly outgassing the chamber after construction. After the chamber had been used for several months, only small changes were exhibited. These were attributed to small pressure increases attributed to diffusion of air through the chamber walls. The 0.6% change in pulse size per day which results can be compensated for by periodic adjustments of the high voltage. Apparent QF for Pu-Be neutrons changed by only 0.2% per day during a 112 day test. It is therefore concluded that gas purity and gas pressure changes can be adequately controlled in sealed detectors employed in portable spectrometers and survey meters. Refilling on a monthly or bi-monthly basis should be adequate for most survey situations.

5.0894, IN-VIVO MEASUREMENT OF RADIONUCLIDES IN MAN
S.H. COHEN, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

The sensitivity, precision and accuracy of the whole-body counter permits the measurement of the long-term biological turnover of various elements in man using low levels of tracer. Knowledge of these turnover rates is required for the assessment of the radiation hazard to man from Sr90 and Cs-137.

Both the absolute levels and spatial distribution of various radionuclides in man are determined. These measurements employ an empirical technique, using an 'on-line' computer to correct for the variable counting response to both geometry and attenuation of gamma photons in individual subjects.

A stochastic model was fitted to long-term strontium retention in a group of men. This model is derived from both a causal path analysis and a maximum likelihood function.

The burdens of Cs137 in a selected population of ten staff members have been measured at monthly intervals for the past 9 years. These data provide information as to the changes in the level of radioactive fallout in the environment. In addition, 450 of the BNL staff have been counted and their absolute levels of Cs137 and K40 measured as a function of age and sex.

As part of a study of grossly obese children, the whole-body K40 was measured in 35 children in order to determine their lean body mass. The total cell mass is correlated with total fat cell mass and other parameters in these children (in collaboration with Knittle).

SUPPORTED BY U.S. Atomic Energy Commission

5.0895, IN VIVO MEASUREMENT OF RADIOACTIVE BODY BURDENS IN SELECTED POPULATIONS

S.H. COHN, Brookhaven Natl. Lab., *Upton, New York* 11973
(AT(30-2)GEN-16)

The technique of gamma-ray measurement by pulse-height analysis provides the most rapid and accurate determination of internally- deposited radionuclide abundance in man. Scintillation spectrometer pulse-height distribution data are analyzed to quantify the levels of cesium-137, zinc-65, potassium-40, and other radionuclides in Brookhaven personnel. In a large-scale study of this kind, constant effort is made to improve the automatic data-handling techniques and the computer analysis of the spectral data.

A 54-detector whole body counter utilizing an on-line computer was constructed and calibrated. The counter is unique in that it incorporates the following properties: high sensitivity and spectral resolution, an invariant response to both the spatial distribution of radionuclides and to body size. The counter also has the ability to provide data on the spatial distribution of rapidly translocating radionuclides in the body.

Results: The operational characteristics of this counter and its associated computer facility were studied, using point sources and distributed sources in a phantom. An empirical technique employing the computer was developed to correct for the variable response to both geometry and attentuation of gamma-photons by the human body. A series of clinical studies were carried out to provide data for the evaluation of the response of the system to variations in counting geometry, body size and weight, and to rapidly translocating radionuclides.

SUPPORTED BY U.S. Atomic Energy Commission

5.0896, IN-VIVO NEUTRON ACTIVATION

S.H. COHN, Brookhaven Natl. Lab., *Upton, New York* 11973

A technique for in-vivo neutron activation analysis of elements in the man has been developed. It is possible with a whole-body dose to the subject of less than 0.25 rad (from fast neutrons) to measure in-vivo whole-body concentrations of Ca, Na, Cl, I, N and P. In the initial effort of measuring the concentration of Ca (49Ca) in the whole body, the first step is to obtain a uniform thermal neutron distribution in order to expose the body uniformly to a standardized quantity of neutrons. The second step is to quantitatively measure the induced activity of 49Ca in the body with a whole-body counter. A 54-crystal whole-body counter and on-line computer is used in the second step to provide a measure of the induced activity independent of its location in the body and the size of the body itself.

Results: Thermal neutron flux densities generated in both tissue- equivalent and water phantoms have been investigated for a number of neutron sources. These have included PuBe, PoBe, and AmBe (alpha,n) sources, and 14-MeV neutrons from a neutron generator. Both the relative and absolute thermal neutron densities have been evaluated. Depth-flux curves obtained from the (alpha,n) sources using bilateral irradiations have given satisfactory curves similar to those generated by 14-MeV neutrons. The new whole-body counter has been used to measure absolute levels of induced 49Ca independent of its localization in the body and the size of the patient.

SUPPORTED BY U.S. Atomic Energy Commission

5.0897, COMPUTER APPLICATIONS

J.S. ROBERTSON, Brookhaven Natl. Lab., *Upton, New York* 11973
(AT(30-2)GEN-16)

The SDS Sigma 2 digital computer is expected to be linked via Brooknet to the central facilities' CDC-6600 computers during the next year. Implementation of this will require programming for communication between the two computers. This will extend the on-line data processing capabilities for the whole-body counter and the EPR systems and will give the Medical Department a remote control terminal for batch processing.

Results: The SDS Sigma 2 computer system has become fully operational for on-line data acquisition and data processing for the whole-body counter and the EPR systems within the limitations of its capabilities. New programs developed during the year include CALDOS for computing the dose rates from arrays of Californium-252 sources at any set of selected points in a 21 x 21 x 21 lattice. Calculations for Californium-252 differ from corresponding ones for radium sources because the attenuation factors for neutrons do not correspond to those for gamma rays.

SUPPORTED BY U.S. Atomic Energy Commission

5.0898, A COMPREHENSIVE APPROACH TO MAJOR FACTORS DETERMINING RADIOSENSITIVITY

A.H. SPARROW, Brookhaven Natl. Lab., *Upton, New York* 11973
(AT(30-2)GEN-16)

The goal is to determine whether radiobiological responses of various groups of organisms are dependent on common variables which would allow the radiosensitivity of different types of organisms to be put into a proper perspective with regard to each other. D sub 37 values of a large number of organisms (viruses to higher plants and animals) are being studied to see if the relative radiosensitivities of these organisms can be explained in terms of various chromosomal parameters and of target theory concepts. These parameters include chromosome and nuclear volume, nucleic acid content and concentration, and molecular weight of the nucleic acid. These variables are being related to the D sub 37 values and to each other. The fine structural morphology of nuclei and chromosomes of higher organisms is under study to see if there are any basic differences which could be useful in explaining relative radiosensitivities.

Results: Data based on the above parameters indicate the existence of eight groups of organisms. Species within each group were not necessarily related according to taxonomical schemes. It was found that: 1) within each group D sub 37 was inversely proportional to chromosome volume; 2) energy absoprtion per chromosome at D sub 37 was nearly the same for each of the organisms within each group but different for each group; 3) the ratio of chromosome volume to the theoretical target volume increased from group to group but was nearly the same for organisms within each group. For the small RNA viruses the ratio of the volume of RNA to target volume was approximately 1, hence, the volume of the radiosensitive target corresponds to the calculated volume of the RNA molecular weight. In other organisms the calculated target volumes were smaller than either the chromosome volumes or the calculated volumes of the DNA. Work under way suggests that certain mathematical transformations may improve the usefulness of the relationship for predicting radiosensitivities.

5.0899, RELATIONSHIP OF PLOIDY, CHROMOSOME SIZE AND RADIOSENSITIVITY

A.H. SPARROW, Brookhaven Natl. Lab., *Upton, New York* 11973
(AT(30-2)GEN-16)

5. RADIATION

The effect of increased ploidy on radioresistance was examined in whole plants (haploids to 20-ploids) and in single-meristematic-cell systems (diploid to 12-ploid). LD sub 50s for whole plants were determined from survival curves and D sub 37 values from terminal stamen hair cells or pollen of several Tradescantia species after exposure to appropriate amounts of super 137 Cs, super 60 Co gamma rays or monoenergetic neutrons. Interphase chromosome volumes (ICV) were determined for all species at the time of irradiation. Mean survival time varies greatly among species. The cellular basis of this variation is being sought.

Results: It was found that the LD sub 50 and D sub 37 values were inversely proportional to the corresponding ICVs. The absorbed energy per chromosome at specified end points for each species was relatively constant for each end point. In several genera investigated, high levels of ploidy 'per se' did not have a radioprotective effect but a small ICV was often, if not always, found in high polyploids. Thus the 'apparent' protective effect seen in some genera can best be explained in the light of a reduced target volume of the chromosome rather than as a consequence of genetic redundancy. However, the latter may influence mean survival time as well as variation in ICV. In cases where diploids and polyploids did not differ in sensitivities ICVs were very similar. So far there are no significant differences between auto- and allo- polyploids. Data on more species are being assembled.

5.0900, ENVIRONMENTAL BIOLOGY - METABOLISM AND PRODUCTION OF A FOREST
G.M. WOODWELL, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

The objective is measurement of the primary productivity of a forest exposed to a gradient of ionizing radiation. Primary productivity is especially useful in appraising effects of any disturbance because it integrates all the physiological processes of the system, providing a single measurement of function useful in both rapid and long-term analyses of function at the ecosystem level. Technical difficulties have prevented widespread use of productivity measurements in terrestrial vegetations. At Brookhaven National Laboratory techniques for measurement of productivity are being developed using both measurements of metabolism under field conditions and growth analysis techniques; gas exchange data, used as an index of metabolism, together with measurement of appropriate environmental variables are punched on tape, a process which allows rapid machine tabulation and correlation of data.

Results: From this work we know now: (1) that CO 2 measurements under field conditions can be used as an index of metabolic rates and, if maintained through long periods, can probably provide an index of productivity as well; (2) exposure to ionizing radiation reduced the efficiency of C fixation proportionately more than it depresses respiration, an effect which introduces one mechanism of death due to irradiation of plants as simply an unfavorable Ps/Rs ratio. This mechanism applies especially to woody plants. (3) That CO 2 fluctuations at night within the Long Island oak-pine forest are frequently great and regular enough to offer the possibility of measuring respiration of the total forest directly by simply monitoring CO 2 concentrations and temperature on a 50 ft. tower. (4) There is a reasonable possibility of developing a simplified sampling system for determining the productivity and nutrient inventory of other forests which have trees of similar form.

5.0905, INVESTIGATION OF THE THICKNESS OF BRONCHIAL EPITHELIUM
P.J. WALSH, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Natl. Insts. of Health, *Durham, North Carolina* 27709

The objective of this study was to determine the location of the basal cells in the bronchial epithelium of the tracheobronchial tree for purposes of dose estimation in the case of inhalation of alpha emitting radon daughters.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0906, OPERATE A RADIATION ALERT NETWORK
M. GEORGEVICH, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Collect daily air samples to determine radiation levels in all states and territories of the U.S. and alert other agencies, concerned with radiation health and safety, when high levels occur.

Approach: Collect air samples for gross-beta using a 0.5 m3/min air flow and a charcoal impregnated filter.

Goal: Analyze daily samples Monday through Thursday and composites on Friday through Sunday for gross-beta at 73 sites throughout the U.S. and its territories.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

5.0907, ANALYZE SELECTED HI-VOL SAMPLES FOR GROSS-BETA RADIATION
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To determine the gross-beta radiation in collected particulate samples.

Approach: The particulates collected on glass-fiber filters on the West Coast and in selected areas where nuclear power generation is projected are measured for gross-beta radioactivity.

Goal: To determine the gross-beta radiation in particulate samples collected at some 26 stations 26 times per year.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

5.0908, RADIOCHEMICAL METHODS AND MEASUREMENTS

B. KAHN, U.S. Environ. Protection Agcy., Natl. Environ. Research Center, *Cincinnati, Ohio* 45213

The objective of this program element is to improve and develop methods of radioanalysis for various media, particularly, air, water, soil, vegetation, and biologic material. In addition, effective techniques for measuring environmental radiation and for sampling environmental media containing radionuclides are to be developed and evaluated.

To assess the movement of radioactive materials in the environment and to evaluate their potential radiation exposure to man, samples of environmental media are collected for analysis of radioactive content, or direct measurements of environmental radiation levels are made in the environs of certain facilities such as nuclear power reactor installations. Efficient, accurate, and reliable analytical and radiation measuring methodologies are therefore of major importance in evaluating environmental radiation exposure to man.

Radiochemical procedures will be evaluated in the laboratory on environmental samples collected from selected sites such as at reactor installations and on laboratory control samples. This evaluation will be conducted for the purpose of refining or developing needed analytical procedures for determining radioactive concentrations in sampled media. Because of their growing use, nuclear power reactor installations primarily will be studied for their contribution to environmental radiation. Assessment and development of analytical means for determining the concentration of radioactive waste products discharged from reactors to the air and water in the environment will be based on samples of waste effluent collected from the reactor site. Environmental radiation levels may be evaluated by use of thermoluminescent dosimeters placed in the field and also on direct field measurements made by electronic instruments.

5.0909, ROLE OF 2-DEOXYGLUCOSE AND OTHER METABOLIC INHIBITORS ON THE RADIATION SENSITIVITY OF CULTURED MAMMALIAN CELLS

H.L. FRIEDELL, Case Western Reserve Univ., School of Medicine, *Cleveland, Ohio* 44106 (W-31-109-ENG-78)

The metabolic inhibitor 2-deoxyglucose is being used to alter the metabolism of Chinese hamster and Strain L cells before, during, and after irradiation of the cells with X-rays. The purpose of this study is to evaluate the role of metabolism in cell injury and recovery from X-radiation. As an extension of this work, environmental factors such as serum and pH will be examined for their possible influence on the effectivenss of metabolic inhibitors and similarly classed agents as radiation modifiers. Part 10 of 22.

5.0910, PULSED ELECTRON BEAM DOSIMETRY

E.C. GREGG, Case Western Reserve Univ., School of Medicine, *Cleveland, Ohio* 44106 (W-31-109-ENG-78)

Absolute beam currents and total delivered charge in a pulsed electron beam have been determined by means of an absorption calorimeter, Faraday cup and Toroidal beam transformer. All these methods agreed to better than 3% on an absolute basis. While these methods suffer from the disadvantage of requiring a vacuum for reasonable accuracy, they can be used as primary reference standards for other devices and techniques that may be used in air or phantoms. Devices under investigation are thermoluminescent LiF-loaded Teflon sheet and rods as well as silicon solar cells. The LiF-loaded Teflon sheet is the most promising for insertion in phantoms while the Toroidal current transformer is most useful for transmission monitoring of electron beams in therapy. We also plan to extend the electron energy range from 0.7 to 7 mev. Part 1 of 16.

5.0911, MERCAPTOCYCLOPROPYLAMINES RADIATION-PROTECTIVE AGENTS

D.T. WITIAK, Ohio State University, School of Pharmacy, *Columbus, Ohio* 43210

Our program is designed to study the synthesis of beta- mercaptocyclopropylamines and related systems and to evaluate these compounds in terms of their ability to protect mice from the effects of ionizing radiation. The proposal discusses theoretical reasons for the desirability of testing such compounds as well as a number of approaches to the stereoselective synthesis of cis and trans isomers of the types desired. It is expected that biological data obtained will be complementary to the work of others relative to the mechanism of action of low molecular weight omega-mercaptoalkylamines.

5.0912, CONCORDE RADIATION WARNING DEVICE TESTS

W. FRIEDBERG, U.S. Dept. of Transportation, Civil Aeromedical Institute, *Oklahoma City, Oklahoma*

This task will be conducted to (a) measure levels of radiation from galactic and solar sources by means of the Concorde radiation warning device, and (b) to compare the data recorded by the British instrument with those obtained by the High Altitude Radiation Instrument System (HARIS) manufactured by Solid State Radiations, Inc., Los Angeles, California. The information obtained will be used to evaluate the sensitivity, accuracy and reliability of the Concorde instrument, to validate its performance in relation to the HARIS package, and to determine its validity and usefulness for the inflight recording of radiation at SST altitude.

Present prototype equipment devices were developed at the Atomic Weapons Research Establishment, Berkshire, England. One of these instruments is on loan to the Office of Aviation Medicine for flight testing, preferably in conjunction with the HARIS package, using the USAF RB-57F aircraft. These aircraft which were previously operating from Kirtland AFB, N.M., are presently assigned to alert/scramble missions at Eielson AFB, Alaska. The operational plan for the deployment of the two aircraft and three crews is authorized by the 59th Weather Wing and monitored by personnel from the Air Force Weapons Laboratory at Kirtland AFB, N.M.

Accomplishments on this project include the following: 1) Concorde instrument modified so that it will operate as a hermetically sealed unit; 2) Rustrak recorder coupled to the Concorde instrument and the recorder modified so that it will operate in a cold compartment at SST altitudes; 3) Dose response relationships of the radiation detectors checked; 4) Aircraft shock-mounts modified so that the Concorde instrument could be installed in an RB-57; 5) Performed pull tests, temperature sensitivity tests and electrical tests to meet FAA standards and Air Force regulations; 6) Consulted with representatives of the Air Force, General Dynamics Corp., and Los Alamos Scientific Laboratory and obtained space for the Concorde instrument next to the HARIS package; 7) Missions are now being flown with the Concorde instrument out of Eielson Air Force Base. We recently received 21 data tapes and they are being analyzed.

5.0914, REMOVAL OF AM-241 FROM HUMANS WITH DTPA

A. BRODSKY, Univ. of Pittsburgh, School of Public Health, *Pittsburgh, Pennsylvania* 15213

The main objectives of this project continue into the fourth year to be aimed at improved understanding and quantitative description of the removal by chelation therapy of americium and plutonium from human cases under treatment. Results already obtained should lead to recommendations for improved treatment for removal of plutonium and transplutonium radionuclides, which are potentially carcinogenic when retained in the body for long periods of time. The studies in this project are particularly focused on an individual who worked with and inhaled americium oxide (Am_2O_3) prior to May, 1967, supplemented by data from other cases, in which both plutonium and americium were taken into the body. In May, 1967, this individual was found by in vivo scintillation counting to have a body burden of about 1.8 microcuries of Am-241, about 1 microcurie of which had already translocated to bone. Measurements of radioactivity in the whole body, body compartments, excreta, and blood showed that infusions of 1 gram DTPA per week were successful in removing more than half the initial body burden during the first two years following treatment. Radioactivity was removed most rapidly from soft tissues, particularly liver, once DTPA infusion was begun in September, 1967. Periods with changed treatment schedules indicate that 1 gram DTPA per week is (after 3-1/2 years) still enhancing the removal rate to about 5 times above that without treatment. Methods for separating chelated from unchelated americium in urine, and summaries of results obtained so far, are in publication. Further studies will aim at elucidating mechanisms of removal of americium and plutonium and development of quantitative models for purposes of risk estimation and treatment planning.

5.0915, ELECTROMAGNETIC POWER ABSORPTION MEASUREMENTS FOR RADAR HAZARDS ASSESSMENT AD SURVEILLANCE SYSTEMS

A.R. KALL, A.R.K. Corporation, *Willow Grove, Pennsylvania* 19090 (F41609-70-C-0031)

Technical Objective: The USAF requires information on power absorbed by man exposed to radiofrequency fields to determine safety/hazard levels and to develop airborne surveillance systems. Power absorbed from radiofrequency (RF) fields by mongrel dogs in the frequency ranges 0.5 - 30 MHZ and 3 - 12 GHZ will be measured in such a manner that conversion efficiencies to infrared radiation (IR) from the surface of the animal can be determined. The spectral distribution of the infrared energy radiated from the animal in the 2 - 20 micron band is to be determined with each exciting radiofrequency.

SUPPORTED BY U.S. Dept. of Defense - Air Force

5.0916, RADIATION DETECTORS FOR USE IN NUCLEAR/CRITICALITY ACCIDENT DOSIMETRY

R. SIWICKI, Inst. of Nuclear Research, *Otwock Swierk, Poland*

For work under risk of criticality an individual activation dosimeter was elaborated to enable rapid selection of the exposed individuals and preliminary dose estimation. The procedure is a laboratory one, and is not in routine use.

Systematic work will be carried out with a view to extend the range of methods in routine use: a) luminescent detectors, b) set of activation detectors for various neutron energy ranges, and c) measurements of biological material (i.e., sodium and sulphur activity). A trial will be made of accident dose assessment by evaluation of routinely used personnel dosimeters.

Methods of neutron dose determination by use of particle track detectors: a) neutron fluence measurement in various energy range, using particle track detectors in contact with fissionable materials, and b) use of atom recoil tracks in polymer foil material for neutron detection. The determination of the detection sensitivity. Preliminary analysis of possible leakage - spectra around water - water reactor and graphite critical assembly.

5.0919, ULTRA LOW LEVEL RADIONUCLIDE ANALYSIS

A.L. BONI, U.S. Atomic Energy Commission, Savannah River Plant & Labs., *Aiken, South Carolina* 29801

The objective of this program is to develop and use ultra low level methods for measurement of trace radioactive and associated nonradioactive materials in the environment of Atomic Energy facilities. The program includes research and development in: 1. Low level counting systems including computer-based programable gamma spectrometry, coordinated high resolution low background (Ge(Li)-NaI) detector systems, high resolution alpha spectrometry, and portable gamma spectrometry for field use. 2. Concentration and separation of radionuclides and trace elements from large volumes of river and ocean water using ion exchange and extraction systems. 3. Gas chromatographic separation and identification of radioactive and nonradioactive organic compounds in liquid effluents. 4. Use of atomic absorption to measure stable elements associated with their radioactive isotopes in environmental samples.

Results to date include establisnment of an ultra low level counting facility with low background counting chambers, on-line digital computer and high resolution, high efficiency, low background detector systems. Basic methods for the concentration of trace radionuclides from large volumes of water have been developed. Preliminary instrumental capabilities for their identification and quantitative measurement have been established.

5.0920, STUDIES IN IODINE METABOLISM

L. VANMIDDLESWORT, Univ. of Tennessee, School of Medicine, *Memphis, Tennessee* 38103 (AT-(40-1)-1643)

We will attempt to identify the iodinated compounds and their rates of turnover in normal and intensely stimulated thyroids of rats and hamsters. Preliminary data suggest that in rats fed a low iodine diet 20-30% of the thyroglobulin has a half-life of 1 to 2 hours. Animals will be used after equilibration of I127 and I125.

Endogenous SCN ion may partially regulate the availibility of iodine to the thyroid and we will measure the alterations in iodinated thyroidal proteins produced by the presence of SCN ion.

The intestinal contents of rats will be examined by paper chromatography to determine the break-down products of biliary thyroxine conjugates. We have shown that thyroxine is absorbed less readily than triiodothyronine and we will search for triiodothyronine production in the intestine.

The I131 from fall-out will be measured each week in animal thyroids from all continents except Africa. This simple procedure

is still an excellent index of biological contamination by fission products.

In rats fed low iodine diets, 20-30% of the thyroidal thyroglobulin has a half-life of 1 to 2 hours; 60% is insoluble and has a much longer half-life. 1% has a half-life longer than 60 days. The distribution of the slowest components has been demonstrated by radioautographs. Preliminary data suggest that SCN ion feeding will increase the quantity of iodine in the pool with the longest half-life.

Radioiodine fall-out has been measured in more that 60,000 animal thyroids during the past 16 years and the data published every 2 to 3 years.

5.0921, BIOLOGICALLY ORIENTED ORGANIC SULFUR CHEMISTRY

L. FIELD, Vanderbilt University, School of Arts, *Nashville, Tennessee* 37203

The chemistry of organic sulfur compounds is being studied, with emphasis on biological relevance. Substances being studied include thiols, aminothiols, sulfenyl derivatives especially iodides, thiolactones, disulfides, and collagen. Biological applications planned, and the relevant chemistry, are as follows: (a) Arthritis - Structural features of penicillamine involved in its diminution of the rheumatoid factor and reduction of rat skin tension are being studied. Mechanisms of these effects also are to receive attention. More effective counterparts of penicillamine will be sought using both derivatives and other thiols. (b) Sulfenyl Derivatives Related to Thyroid Function - Model compounds are being investigated in the hope of understanding the stability and reactions of protein-sulfenyl compounds (i.e. RSX), the nature of RSX reactions with antithyroid substances, possible correlations of antithyroid activity with either reactivity of the agents (to RSX) or stability of the products (RSSR'), and whether RSX can effect substitution of phenols. (c) Histoplasmosis - Numerous classes of sulfur compounds are being screened against H. capsulatum. Emphasis presently is on the chemistry and screening of acyl and related disulfides. (d) Disulfide Linkages - The chemistry will be studied of insertion and multiple-bond reactions with disulfides, of oxidation, of small-ring disulfides, and of unsymmetrical disulfides. In all parts, (a)-(d), appropriate products also are being tested as potential antiradiation drugs.

5.0922, CLINICAL AND HEMATOLOGIC STUDIES OF IRRADIATION - CLINICAL AND LABORATORY CHANGES AFTER TOTAL-BODY IRRADIATION

C.L. EDWARDS, Oak Ridge Associated Univs., *Oak Ridge, Tennessee* 37830 (AT-(49-1)-GEN-33)

This study is directed at developing better methods of total-body irradiation therapy and for assessing and treating accidental radiation injury. Coincidentally important information is obtained to more precisely define man's response to radiation at different dose rates. Some patients with chronic malignant disorders such as chronic leukemia and lymphomas are treated with whole-body irradiation exposure of 50 to 250 R at a dose rate of 1.5 R per minute (METBI), either as a single acute exposure or in daily exposures of 30 R. Others are treated with 100 to 250 R at 1.5 per hour (LETBI).

Results: Patients exposed to the lower exposure rate radiation (LETBI) had fewer gastrointestinal symptoms than those treated with 1.5 R/min (METBI) whether as a single acute exposure or fractionated into 30 R exposures daily. There appears to be a decided dose-rate effect when comparing the hematologic response of patients with chronic granulocytic leukemic to exposure of 100 R in LETBI compared with 50 R and 100 R exposures in METBI.

SUPPORTED BY U.S. Atomic Energy Commission

5.0923, NUCLEAR MEDICINE AND SCANNING - INSTRUMENTATION

A.C. MORRIS, Oak Ridge Associated Univs., *Oak Ridge, Tennessee* 37830 (AT-(40-1)-GEN-33)

The primary objective of this project is to provide the necessary engineering services and facilities for producing special electronic instruments needed in the Medical Division's clinical and research programs. The new devices are used to locate and measure radioactivity in patients, to monitor the physiologic variables of patients receiving total-body irradiation, and to interface remote instruments to an on- line computer. Current areas of interest include the computer analysis of radionuclide measurements and scans, computer interfacing of a gamma- ray camera system for improved analysis and read-out capabilities, an improved instrument for measuring red-cell fragility, a physiologic monitoring system for measuring radiation effects, and the development of a low-noise preamplifier for red-cell sizing studies.

Secondarily, our project maintains the large variety and number of electronic instruments used at the Medical Division.

Results: Constructed and Operating: whole-body counters (2), physiologic monitoring system, cell-sizing preamplifier, scintillation counter interface to computer 4 miles away, Analytrol densitometer interface to computer, scintillation scan color-recording rescanner, linear scanner, and an improved whole-body scanner.

5.0924, RADIATION DOSIMETRY RESEARCH

J.A. AUXIER, U.S. Atomic Energy Commission, Health Physics Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

The development of dosimetry theories, systems, and techniques for describing the radiation fields in which human exposures have occurred or might occur provides the general objective of this research. Efforts are made specifically to correlate the radiation field with observed biological effect. Theories and calculation are being tested with experiments to determine the dose and the recoil particle energy distributions within tissue equivalent phantoms irradiated by neutrons and gamma rays. With these studies and the refined estimates of air dose in Hiroshima and Nagasaki, it is possible to compute the dose for survivors in utero. Much emphasis is placed on the development of solid state detector systems. In particular, research is directed toward the use of polyester materials for the registration of alpha particles, heavy ions, and fission fragments, and toward the development of better compounds for use in thermally stimulated exoelectron emission studies. Spectrometry research countinues to play a large role in the overall program. Organic scintillators are being purified by zone refining techniques in order to improve the light output of the crystals and to provide good material with which to grow large crystals.

Results: On the basis of medical records of the Atomic Bomb Casualty Commission, the RBE of neutrons for inducing leukemia has been determined based on the current knowledge of the neutron and gamma air dose in both Hiroshima and Nagasaki. Calculations of depth dose and LET distributions in tissue equivalent phantoms were extended to study the dispersion of collimated, incident monoenergetic neutron beams within a cylindrical phantom, and for implanted Cf252 sources. Extensive measurements of neutron and gamma dose have been made near tissue bone interfaces in a tissue equivalent phantom when irradiated with fission neutrons. A very sensitive solid state dosimeter has been developed.

SUPPORTED BY U.S. Atomic Energy Commission

5.0925, HEALTH PHYSICS RESEARCH REACTOR AND MONOENERGETIC RADIATIONS FACILITY

J.A. AUXIER, U.S. Atomic Energy Commission, Health Physics Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

The Health Physics Research Reactor (HPRR) and its related facilities provide a versatile and efficient irradiation center in which dosimetry research and radiobiological research are conducted to the best advantage of each. A dose rate range of approximately 12 orders of magnitude without a change in spectrum or neutron-to-gamma radiation dose ratios is the major advantage of the HPRR. The experimental program covers areas in radiology in addition to the research in dosimetry, radiation physics, and shielding.

5. RADIATION

The major effort in the future will be directed toward more comprehensive documentation of dose and spectrum profiles throughout the exposure for a variety of experimental configurations so that preparation and experimental time for experiments can be shortened. Reactor power and neutron dose rate normalization techniques will be improved for more efficient operation.

The ORNL 3 MV Van de Graaff Facility has been obtained for dosimetry research, stopping power measurements, LET studies, and dosimeter development and evaluation.

Results: Each year, the HPRR is used to implement the experimental programs of about 20 organizations ranging from national laboratories to universities, in addition to its primary role in the ORNL Health Physics Division. Increased emphasis in the area of nuclear accident dosimetry has led to greater confidence in the average laboratory's ability to handle dosimetry of criticalities. Biomedical and health physics research has continued to increase as has the percentage of total irradiations utilizing the pulse mode.

SUPPORTED BY U.S. Atomic Energy Commission

5.0926, RADIOLOGICAL AND HEALTH PHYSICS INFORMATION CENTER FOR INTERNAL EXPOSURE

S.R. BERNARD, U.S. Atomic Energy Commission, Health Physics Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

The Center attempts to index under appropriate key words the significant data relevant to estimation of absorbed dose from radionuclides taken into the body. Included are purely physical data on decay schemes and absorbed fractions of photon energy for body organs, as well as shape, size, density, and elemental composition of organs of the body. Data are accumulated on uptake and residence times in various organs. To be applicable to man, the data on experimental animals require critical review and extrapolation, and this is done to a limited extent.

Results: Over 6600 reports are entered in the system and are indexed by some 1000 key woords.

SUPPORTED BY U.S. Atomic Energy Commission

5.0927, HUMAN CHROMOSOME ABERRATION YIELDS FOLLOWING CHRONIC RADIATION EXPOSURES

J.G. BREWEN, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

Human peripheral lymphocytes are being irradiated with Cs137 gamma rays over periods of time up to 72 hours. The doses employed range from 100-500 rads. The purpose of the experiments is to ascertain, as accurately as possible, the precise hazard to human somatic chromosomes from chronic radiation exposures. Exposure time will be increased until the yield of chromosome aberrations per unit dose no longer decreases significantly. Dose response curves will then be done at these exposure times and coefficients of aberration production calculated. From these coefficients it will be possible to make estimates of the abberration yields expected from very low chronic doses.

Results: Lymphocytes have been exposed to 200 rads over periods up to 24 hours. The yield of aberrations observed after a 24 hour exposure is only 25 per cent of the yield when the same dose is given in 3 to 60 minutes. Preliminary data on a dose response curve with a 24 hour exposure indicate the yield increases predominantly linearly with dose with a small two-track contribution.

SUPPORTED BY U.S. Atomic Energy Commission

5.0928, COMPARATIVE IN VIVO - IN VITRO RADIOSENSITIVITY OF MAMMALIAN PERIPHERAL LYMPHOCYTES

J.G. BREWEN, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

Chromosome aberrations induced by acute radiation exposures to marmoset peripheral lymphocytes are being studied. The radiation exposures are given to the cells after blood is withdrawn from the animal and the animals, themselves, are given whole body exposures following which blood is drawn. The irradiated animals will be monitored for over a year in order to study the kinetics of aberration loss. These studies will finally answer the question of whether cells in the living animal have a different radiosensitivity than cells in tissue culture.

Results: Sufficient 'in vitro' data has been collected to construct a dose response curve. The shape of the curve follows predominantly dose- square kinetics and the yields of aberration production are not significantly different from those obtained when human cells are irradiated.

SUPPORTED BY U.S. Atomic Energy Commission

5.0929, DUAL PURPOSE BLAST SHELTERS IN URBAN TRANSPORTATION SYSTEMS

G.A. CRISTY, U.S. Atomic Energy Commission, Oak Ridge National Lab., *Oak Ridge, Tennessee* 37831 (W-7405-ENG-26)

To develop information on the possible exploitation of major urban development and redevelopment projects on civil defense blast shelters with particular emphasis on underground transportation projects. The information developed will be limited to the 54 SMSAs having more than one-half million persons in the 1960 census and will generally be projected through the 1970-80 time frame. Projected data will also be developed for the number of freeway interchanges planned for these same SMSAs which could be used to incorporate blast shelters. The kind of information to be gathered includes: size and shape of the underground spaces which would be usable as shelters with some attempt to estimate shelter hardness. Comparison of the value of the space potential in these structures will be obtained by comparing the amount of space already available in the same area and by comparing the total number of such spaces with the population in each of five types of areas within each SMSA.

Results: Data has been received and processed for 31 of the 54 SMSAs. A progress report has been issued on the 31 cities. A total of over 5 million potential new blast shelter spaces were located and compared with the population within five area classifications. This compares with nearly 9 million PV-71-81 shelter spaces in the 100 largest SMSAs.

SUPPORTED BY U.S. Atomic Energy Commission

5.0930, RBE OF 60 MEV-PROTONS FOR LATE SOMATIC EFFECTS IN MICE

E.B. DARDEN, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

This is a joint AEC-NASA project set up to study RBE of protons with energies comparable to those found in proton spectra in space, particularly in solar proton events. Approximately 3200 8-week-old female RF mice were irradiated in replicates with single whole-body doses of either 60-MeV protons in the Oak Ridge Isochronous Cyclotron or with 300 kVp X rays. Thirty-day survivors were observed for late somatic effects. A complete necropsy, including cranial contents was performed on dead and moribund animals, and in two hundreds or more tissues obtained for histologic purposes with the intention of making a thorough study of the pathology.

Results: Preliminary results on all major portions of the work are available and suggest that the RBE of 60-MeV protons for life shortening, cataractogenesis, increase in body weight, and oncogenic effects is not greatly different from one, and probably a little less in most instances, in agreement with published findings on acute effects of the same radiation in these animals.

SUPPORTED BY U.S. Atomic Energy Commission

5.0931, CHEMICAL PROTECTION AGAINST IONIZING RADIATION

D.G. DOHERTY, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

The objectives of this program are to develop improved compounds to protect mammals against the damaging effects of ionizing radiation, improve assay systems for their evaluation and investigate their mechanisms of action. The problem of providing chemical protection to mammals against ionizing radiation has been intensively studied over the past 20 years and it has been

firmly established that prior chemical treatment can, in some fashion, reduce radiation damage in both 'in vitro' and 'in vivo' biological systems (mammals, bacteria, phage, DNA, enzyme systems). The radiation dose reduction factor has been raised from slightly better than one to nearly three, broad outlines for structures necessary for protective activity defined and several hypotheses as to their mechanism of action developed. However, the effective compounds in animals suffer some deficiencies such as low therapeutic index, low activity requiring a large dose for effective protection and restricted routes of administration. We propose to utilize and build on this acquired knowledge to develop more effective compounds, and study their modes of action both singly and in combination with other effective treatments such as post radiation bone marrow transplantation. The animal used will be the mouse and its three most important systems: bone marrow, intestinal and immune responses.

Results: We have extended our quantitative marrow cell response study to allogeneic and xenogeneic situations. Allogeneic marrow gave a triphasic response similar to syngeneic with an LD 50 200 r lower. Chimaerism was dependent on both cell and radiation dose. Xenogeneic required large cell doses and gave poor long term survival. With L. H. Smith we have developed an 'in vitro' bone marrow assay system for protective compounds which has the virtues of being relevant to the animals' survival, less complex and dependent on toxicity and easier to interpret mechanistically.

SUPPORTED BY U.S. Atomic Energy Commission

5.0932, CIVIL DEFENSE IN THE SOVIET UNION

J.S. GAILAR, U.S. Atomic Energy Commission, Oak Ridge National Lab., *Oak Ridge, Tennessee* 37831 (W-7405-ENG-26)

Objective: To investigate Soviet civil defense in all its aspects, largely through a thorough survey of the Soviet unclassified literature on the subject, to include, for example: (1) Aims and goals of Soviet civil defense, (2) Methods for reaching these objectives, (3) Extent to which implementation has taken place, (4) Nature and scope of the present program, (5) Degree to which civil defense is endorsed by Government and Party leaders, (6) Organization and administration of the program, (7) Education and training of the population, (8) Methods of warning the population, (9) Shelter construction, (10) Individual means of protection (such as gas masks and protective clothing), (11) Evacuation procedures, (12) Rural civil defense, (13) Drills and exercises, (14) Measures to protect essential industries, transportation, communication, power supplies, (15) Rescue and repair operations in stricken areas, (16) First aid measures for the injured, and (17) Means to prevent panic.

Results: A view of over 100 articles on Soviet civil defense indicates: Mandates from both Party and Government in recent years to strengthen civil defense have led to a substantial civil defense program with emphasis on the protection of essential workers by means of shelters and dispersal, and evacuation of everybody else to the country with provision of fallout protection. Some shelters have already been built in and near plants, and plans for evacuation are both elaborate and detailed. Civil defense instruction is compulsory and widespread with about 100 million Soviet citizens having received formal civil defense training. Manuals such as a 341-page rural CD handbook attest to the comprehensiveness of the program.

SUPPORTED BY U.S Atomic Energy Commission

5.0933, LET DISTRIBUTIONS OF IONIZING RADIATION

R.N. HAMM, U.S. Atomic Energy Commission, Oak Ridge National Lab., *Oak Ridge, Tennessee* 37831 (W-7405-ENG-26)

The biological effect of the absorption, in tissue, of a given amount of energy as generally assumed to be related to the linear energy transfer (LET) of the radiation. Consequently, for several years there has been an interest in developing an instrument by which the LET distribution of the radiation can be determined. Spherical proportional counters have been used in the past for this purpose, but the sphere is a particularly inconvenient geometry to use. A study of this problem has been undertaken in order to determine a more convenient and more reliable means for determining LET distributions of ionizing radiation. Monte-Carlo methods are being used to permit LET distributions to be determined from pulse height measurements made with counters of arbitrary geometries and also to allow other factors, such as angular distributions of the incident particles, to be taken into account. This work will permit the use of less expensive, more accurate, and easier to use equipment for monitoring purposes.

Results: Monte-Carlo calculations of the track length distributions of ionizing radiation in cavities of various shapes have been made. A Monte-Carlo method of unfolding LET spectra from pulse-height measurements made with energy proportional counters of various geometries has been developed. Good agreement has been obtained between spectra measured with both cylindrical and Rossi spherical counters.

5.0934, HASTY RURAL SHELTERS AND IMPROVISED LIFE-SUPPORT EQUIPMENT

C.H. KEARNY, U.S. Atomic Energy Commission, Oak Ridge National Lab., *Oak Ridge, Tennessee* 37831 (W-7405-ENG-26)

Objective is to design, build, and evaluate improved hasty shelters (that average rural Americans can build for themselves during an escalating crisis in 48 hrs. or less, that have radiation protection factors of at least 1,000, and that are capable of withstanding blast overpressure up to 10 psi) and also improvised life-support equipment needed by shelter occupants--including improvised shelter ventilating devices, a fallout monitoring instrument, lights, sleeping equipment, a bailing pump, etc. Because rural Americans today lack such knowhow in keeping with the dangers many of them would face (if a massive nuclear attack occurs, even as early as 1970), this updated civil defense knowledge is needed.

We are securing this practical knowledge by first designing and building several versions of each needed item, then having it built for several months of preliminary evaluation, then writing simple illustrated instructions to enable an average rural American family to build the most promising design, then having typical rural families build the item, instructed only by these written instructions. Thus the practicality of the design, the average man-hours of construction time, etc, are determined--always tied in with the abilities and tools of typical rural Americans and the availability of very common building materials. Field work to date has been confined to rural areas of Eastern Tennessee.

Results: Results to date include: (1) Invention of a shelter-ventilating device capable of pumping 500cfm through a typical fallout shelter, yet requiring only 0.05 hp. This is called the 'Kearny Ventilator' by OCD and the Army; military specifications have been approved and distributed, (2) Design and preliminary testing of improved trench shelters, lights, a bailing pump, a '15 cent' electrostatic monitoring instrument, and shelter furnishings.

5.0935, RADIATION-INDUCED MUTATIONS IN MICE

W.L. RUSSELL, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

The objective of this program is the exploration of the basic principles of radiation genetics in the mouse which will help in the evaluation of the genetic hazards of radiation in man. Estimation of these hazards, originally derived from work with 'Drosophila', is now based largely on the experimental findings with mice. This change in evaluation of risks was not merely a substitution of one set of quantitative values for another, it also involved major discoveries at the basic level. Perhaps the most important of these was the finding, from dose-rate studies, that repair of genetic damage can occur when the radiation dose is spread out in time. The discovery of this effect and its subsequent extensive exploration were made using the specific locus method for detecting gene mutations.

The current work is concentrating on an entirely different class of genetic damage, namely, chromosomal aberrations, in order to see if these follow the same pattern of repair. The particular aberration chosen for study, as an example of this class, is X-chromosome loss, which, in man, is the cause of the abnormality known as Turner's syndrome.

Results: Incidence of X-chromosome loss are being scored in the offspring of female mice exposed either to 400R of X rays, at approximately 80R/min, or to 400R of gamma radiation, at approximately 0.6 R/min, from a Cs137 source. The frequency at the low dose rate is significantly below that at the high dose rate, the current ratio being about 0.4. Thus, it would appear that the genetic hazard from this type of chromosomal aberration, like that from gene mutations, will be less at a low dose rate then at a high one.

5.0936, A COMPUTER METHOD FOR ANALYSIS OF DATA ON MOUSE REPRODUCTION

L.J. SERRANO, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

Objective: To develop a system using a computer to simplify analysis of data on productivity resulting from the operation of a breeder colony or from studies using reproduction as an experimental variable.

Reason: Although reproduction is a commonly used experimental variable in many fields of biology, few experiments can be compared satisfactorily. Although variables that influence fertility in the mouse may be similar to those affecting human fertility data on the biology of reproduction from breeding colonies are infrequently used. This is in part due to the complexity of reproduction, large amount of data usually collected, and the great number of calculations necessary to analyze the data.

Procedure: Utilizing our computer technology resources, we have developed a system for arraying the data in tables that facilitate analysis and permit correlations, groupings, and comparison of data that might not otherwise be feasible.

Test Object: Information from the large breeding colony in a low level radiation experiment and several reproduction experiments will provide the data base.

Results: Computer-prepared analyses have been compared with manually prepared analyses to test the accuracy and cost of the system. The computer system was found to be more accurate, much less expensive, and allows more extensive use of available data.

5.0937, RADIOLOGICAL AND HEALTH PHYSICS - ESTIMATION OF INTERNAL EXPOSURE

W.S. SNYDER, U.S. Atomic Energy Commission, Health Physics Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

Estimates of absorbed dose to body organs following intake by inhalation or ingestion are being developed. The studies supply estimates for consideration of committees of the International Commission on Radiological Protection (ICRP) and the National Council on Radiation Protection and Measurements (NCRP) with a view to revision of their recommendations on internal exposure. Procedures are available for estimating dose to lung or to the gastrointestinal tract on the basis of the ICRP lung model ("Health Phys. 12, 173, 1966"). Estimates of dose to bone and bone marrow are under development using the methods of Spiers.

Results: Special studies now substantially complete provide for estimation of dose to red bone marrow for photon emitters and to the bladder wall from radionuclides in urine. The dose distribution in the body from a large 'cloud' of a photon emitter (radioactive gas) is partially complete, and dose from beta emitters is in hand. Dose estimates for a number of radionuclides are in advanced stages of completion; these include tritium, the iodines, cesium, strontium, radium and plutonium.

5.0939, THEORETICAL RADIATION DOSIMETRY

H.A. WRIGHT, U.S. Atomic Energy Commission, Oak Ridge National Lab., *Oak Ridge, Tennessee* 37831 (W-7405-ENG-26)

An understanding of the various interactions that high energy particles (e.g., protons, neutrons, and pions) undergo with matter and, particularly, with tissue, is essential in assessing the hazards from these radiations. Detailed Monte-Carlo calculations, taking into account these interactions, are made in order to determine the spatial distribution of the absorbed energy as well as the relative contribution to the absorbed dose from various physical processes. The general concept of radiation dose is under study in order to try to understand the extent to which the purely physical properties of radiation are responsible for its biological effectiveness. Joint work with the Health Physics Group at CERN (European Organization for Nuclear Research) Geneva, Switzerland, is in progress on research problems in the dosimetry of high-energy pions and nucleons and one member of the staff is in Geneva this year. Calculations are made and the results compared with experimental measurements made with beams of pions and nucleons from the CERN accelerators.

Results: An initial study has been made in collaboration with the experimental Health Physics Group at CERN, Geneva, Switzerland, of the absorbed dose in tissue equivalent material due to beams of postive and negative pions. A new 'free-nucleon' model, which neglects the effects of nuclear structure and nuclear binding by considering the nucleons of the target material to be free, initially at rest, and uniformly distributed throughout the medium, has been used to calculate absorbed dose as a function of depth on a tissue slab.

5.0940, NUCLEAR SAFETY INFORMATION CENTER

F.A. GIFFORD, U.S. Dept. of Commerce, Air Reso. Atm. Turb. Dif. Lab., *Oak Ridge, Tennessee* 37830 (AT(40-1))

Objective: To provide the meteorological input to the Nuclear Safety Information Center (NSIC), which serves as the focal point for the collection, storage, evaluation, and dissemination of nuclear safety information. Provide consultant service to the Atomic Energy Commission and its contractors on specific questions, including air pollution, radiation protection, nuclear accidents, reactor hazards, and environmental quality. Prepare summary and state-of-the-art reports on these functions.

Procedure: Continuing review and abstracting of articles for the computer files of NSIC, and continuing preparation of reports and studies as required.

Results: Abstracting of meteorological articles averages 30 per month. Specific questions requiring a meteorological search average several per month.

5.0941, CORRELATION OF DEPTH DOSE DISTRIBUTION PATTERNS WITH BIOLOGICAL EFFECTS IN SWINE FOR CO-60 GAMMA RAYS, 14 MEV NEUTRONS AND FISSION NEUTRONS

L. WADE, Univ. of Tennessee, U.T. A.E.C. Agric. Res. Lab., *Oak Ridge, Tennessee* 37830 (AT-40-1-GEN-242)

There is at present, little or no information available on the relative biological effectiveness of gamma rays and neutrons in producing radiation damage to large animals. Research in this area has been hampered in part by the difficulties involved with determining the neutron dose to a specific target organ in a large animal.

Depth dose distribution patterns will be calculated by computer for each type of radiation and correlated with specific quantitative biological end points in swine which have already been irradiated at the VDRIF, the HPRR, and Project HENRE.

Results: Depth dose distributions were calculated by personnel at Health Physics Division, ORNL, for swine exposed to 14 MeV neutrons or a mixed fission neutron - gamma field. The

depth dose distribution for Co60 gamma irradiation was obtained by measurements with radiophotoluminescent glass rod dosimeters. An RBE of approximately 0.5 was calculated for fission neutrons and 14 MeV neutrons. Calculations were made of the dose delivered to the gastro-intestinal tract and bone marrow for each type of radiation field.

5.0943, WHOLE BODY RETENTION AND DISTRIBUTION MEASUREMENT OF RADIOISOTOPES IN MAN

F.J. PIRCHER, U.S. Veterans Administration, Hospital, *Houston, Texas* 77031

Results and conclusions: The following work was carried out: (1) Determination of sensitivity and resolution of the instrument through the measurement of LSF and through scanning of a slanted cylinder using a 19-hole 3-inch focused collimator and a 43-hole 5-inch focused collimator. (2) Measurements of systems dead time and derivation of correction factors. (3) Systematized phantom work using sources of 2- 1000 cc of volume containing CO-57, I-131, and Sr-85 to determine the effect of source-volume, activity, and geometry on counts per microcurie. (4) Determination of transmission co-efficients for Co-57, I-131, and Sr-85 using the systematized phantom and human subjects. (5) Further editing and modifications of the computer program.

The results indicate that the instrumental set-up and the computer program are such that it has become possible with the arrival of a large-sized table a few days ago to obtain good approximations of the actual distribution and retention of radioisotopes in men through in vivo measurements. This will provide useful information for clinical diagnosis, for dosimetry of internal radiation, for evaluation of radiopharmaceuticals and of accidental exposures to internal emitters.

Plans for future: Completion of the systematized phantom work, initiation of measurements with the Alderson phantom and resumption of the in vivo measurements in normal subjects and in patients receiving nuclides and/or labeled compounds for medical purposes.

5.0947, P-N JUNCTION DIODE DOSIMETRY WITH TEMPERATURE COMPENSATION

L.H. DEITERMAN, U.S. Veterans Administration, Center, *Temple, Texas* 76501

At this time essentially all of the goals as stated in the original protocol for this project have been accomplished. We have studied in detail the temperature dependence of the radiation induced photocurrent and photovoltage for both silicon P-N Junction diode and gold barrrier diodes. We have developed two different methods of overcoming this temperature dependence. They are: a) Thermistor compensation of the d.c. gain of the preamplifier. b) Load impedance compensation of each diode in photocurrent mode.

We routinely use these diodes as radiation detectors for high energy (E greater than 1 MEV) gamma rays and x-rays. In fact, we have been contacted by the Texas Regional Medical Physicists organization located at M.D. Anderson Hospital, Houston, Texas, concerning the routine use of these detectors to map all megavoltage radiation fields in preparation for computer dosimetry of X-ray therapy treatment planning.

The larger sensitive volumes provided by the gold barrier type of detector allows their use in radiation fields below one rad per minute. This added sensitivity is needed to measure the dose distribution around radium implants, cobalt-60 wire implants, etc.

We have constructed several of these P-N junction diode probes and by eliminating the effect of diode temperature we have a radiation detector which can be used in many environments in which heretofore their use was impossible.

5.0950, RADIATION SAFETY COMMITTEE (U-109)

J.O. JENSEN, Utah State University, Agricultural Experiment Sta., *Logan, Utah* 84321 (UTA00557)

OBJECTIVE: Oversee all work, research or teaching, involving ionizing radiations whether these arise from radioactive isotopes or X- ray machines. The Committee is concerned that these operations are carried out with safety to the operators, students, and the general public, and that they are in compliance with safety rules established by the U.S. government.

APPROACH: Periodic surveys will be made of laboratories in which ionizing radiation is used. This includes about ten laboratories using radioactive isotopes, three laboratories using X-ray eqpupment, and two laboratories using neutron moisture meters. In some of these the primary use of isotopes in in research and graduate instruction, while in other the primary use if in formal course work. Monthly film badge service in also provided to the laboratories as needed

PROGRESS: All project leaders and instructors who use sources of ionizing radiations file a description of their experiments with the committee. The committee may require a preliminary 'dry run' of the proposed experiment under the supervision of its representative, the Radiological Safety Officer, who may suggest safety precautions. The Radiological Safety Officer also makes periodic surveys of laboratories for radiosotope contamination and supervises the film badge service. Periodic surveys are made of laboratories in which ionizing radiation has been used. This includes about ten laboratories using radioactive isotopes, three laboratories using X-ray equipment, and three laboratories using neutron moisture meters. In some of these the primary use of isotopes is in research and graduate instructions, while in others the primary use is in formal course work. Monthly film badge and finger badge service is also provided to the laboratories as needed.

5.0951, RELATIONSHIP OF LOCAL RADIATION DOSE OF BONE-SEEKING RADIONUCLIDES TO DAMAGE

W.S. JEE, Univ. of Utah, School of Medicine, *Salt Lake City, Utah* 84112 (AT(11-1)-119)

The comparative toxicities of a single LVO chronic dose of a bone- seeking radionuclide Ra226, Ra228, Th228 and Sr90 ranging between 100 and .00068 mu c/kg upon the skeletons of adult beagles are being studied using techniques which will relate local radiation dose to resulting damage. The study was designed to determine the comparative toxicities of these radionuclides in beagles which will contribute information for extrapolation to define the maximum permissible dose of these various bone seeking radionuclides in man. Local radiation dose studies involved quantitative and qualitative autoradiographic techniques to define the initial deposition (non-uniform distribution of the radiation in contrast with the assumed uniform distribution derived from whole body retention), alterations in distribution with time (change in pattern and concentration due to internal remodeling), volume of cells at risk and loss of radionuclide from long term exchange. Radiation damage studies involved quantitative histopathologic techniques to determine incidence of bone tumors, abnormal bone tissues, changes in circulation and rates and patterns of internal reconstruction in selected cortical and cancellous bones. Microradiographic and quantitative histological studies are used to determine the characteristics of cortical and cancellous bones with age.

Results: Current activities have concentrated on improving methodologies for determining local bone dosimetey with a combination of two techniques: 1) alpha-particle or fission fragment registration in thin polymer foils by etching and 2) automatic counting of etched perforations by local evaporation of a thin metal layer with an electric spark. LVB bone section from dogs injected with 0.305 muCi of Pu 239/Kg was 3.2 pCi/cm squared and from a dog injected with 0.0148 muCi of Pu 239/Kg was 0.22 pCi/cm squared.

5.0952, RETENTION AND DOSIMETRY OF BONE SEEKING RADIONUCLIDES IN BEAGLES

R.D. LLOYD, Univ. of Utah, School of Medicine, *Salt Lake City, Utah* 84112 (AT(11-1)-119)

The retention of Am241, Pu239, Ra228, Th228, Ra226, Ra224, Pb210, and Sr90 in beagles injected as young adults has been determined for up to more than 14 years after injection. For all of these radionuclides except Pu239, measurements have been made by total-body counting. Distribution among the various organs and tissues has also been studied. Calculation of average skeletal radiation dose-rates and cumulative doses are based upon these retention and distribution measurements. The relationship between observed biological effects of the injected radioactivity and radiation dosage parameters is being investigated.

SUPPORTED BY U.S. Atomic Energy Commission

5.0953, SPECULATED RISK TO BONE AND LIVER FROM 239PU

C.W. MAYS, Univ. of Utah, School of Medicine, *Salt Lake City, Utah* 84112 (AT(11-1)-119)

The permissible body burden of 239Pu in radiation workers is 0.04 mu Ci. A literature survey indicates that the Pu reaching the circulatory system from occupational exposure may redeposit roughly half in bone and half in liver. For a constant 0.02 mu Ci 239Pu in bone and 0.02 mu Ci 239Pu in liver, the 50 year doses to man are 14 and 57 rads, averaged over these respective organs. Probabilities of radiation- induced tumors from these doses are estimated as follows: Bone Cancers- Threshold model-0%, Dose-rate model 1%, Lifespan dose model -5%. Liver Tumors- Threshold model 0%, Dose-rate model 2%, Lifespan dose model 10%.

The threshold model is based on radium-containing humans, whereas the dose-rate and lifespan dose models are extrapolated from our experience with 239Pu in dogs. These risks refer to adult, not childhood, exposures. The hazards to the lung from inhaled plutonium, and hazards to wound puncture sites were not estimated.

No tumors attributable to 239Pu have yet been reported in 37 humans exposed to plutonium who were studied by Wright H. Langham. These persons are estimated to contain 0.04 to 0.54 mu Ci 239Pu and average about 0.12 mu Ci. The dose-rate model and the lifespan dose model, respectively, predict 1 and 5 bone cancers and 2 and 10 liver tumors among these 37 individuals at 50 years burden time whereas the threshold model predicts zero. The threshold model would be favored if the trend of no observed tumors attributable to 239Pu continues, but radiation- induced cancers in humans are notorious for their delayed appearance, and 50 years of burden time has not yet elapsed.

Improved estimates of the actual risks to humans of internally- deposited 239Pu are urgently needed. The full utilization of nuclear power will depend greatly upon how well these risks can be evaluated.

5.0954, BONE CANCER INDUCTION BY RADIONUCLIDES INCIDENCE VS DOSE

C.W. MAYS, Univ. of Utah, School of Medicine, *Salt Lake City, Utah* 84112 (AT(11-1)-119)

Dose-response relationships have been reviewed for several bone- seeking radionuclides in dogs, rodents, and humans. This includes beagles injected with 239Pu, 228Th, 228Ra, 226Ra, or 90Sr at the University of Utah; rats injected with 90Sr by Y.I. Moskalev et al., mice injected with 90Sr or 226Ra by Miriam Finkel et al., dial painters and other humans containing 226Ra and 228Ra by R.D. Evans et al., and A. J. Finkel et al.; and German patients injected with 224Ra who are being followed by H. Spiess.

For the beta-emitter 90Sr, a sigmoid dose-response relationship is seen, characterized by a low-risk region in which few if any bone cancers have been induced. This suggests that considerable recovery from beta-irradiation is possible, provided that the dose-rate is sufficiently low.

For the alpha-emitters, data on 226Ra in humans supports a practical threshold, below which few if any cancers should be induced; while data on 226RA in mice support a linear relationship in which cancer induction increases in direct proportion to dose, provided that the dose is not excessive. The other alpha-emitter results, each considered separately, can rule out neither the linear nor the threshold models although taken collectively, the threshold model seems better supported. It is possible that in general, the most probable response at low dosage is a sigmoid relationship somewhere in between the linear and threshold models.

5.0955, EFFECTS OF RADIOSTRONTIUM IN MINIATURE SWINE

W.J. CLARKE, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

This study has as its main objective an increased understanding of the potential hazard of radiostrontium to large animals and man. The work is defining the biological effects of daily ingestion of Sr90 in miniature swine, a large animal species more comparable to man than the smaller laboratory animals. Approximately 160 animals are presently on daily feeding levels of from 1 to 625 muCi of Sr90. Nearly 1000 animals have been involved in the project since its inception in 1958.

RESULTS. Litters from the parent generation of swine, which ingested Sr90 from 9 months of age, showed no significant differences in litter size, percent stillborn, or birth weight between controls and animals ingesting up to 625 muCi per day. Among litters from swine exposed to Sr90 from conception (F1 generation), there were no significant differences in feeding through 125 muCi per day. There have been 73 cases of hematopoietic disorders in swine ingesting Sr90, and 2 in controls. Significant increases in these disorders have occurred only in the 125 and 625 muCi per day groups. Bone tumors have been seen in 7 animals of the 125 annd 625 muCi per day group.

5.0956, RADIATION DOSIMETRY

W.A. GLASS, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

This study is primarily concerned with determining how to measure radiation to obtain correlation with biological effects. This is done by conceiving physical quantities that may serve the purpose, studying the principles that relate them to others previously known, determining how they are to be measured, and establishing how useful they are in correlating biological phenomena. Theoretical methods exist for calculating the probability density of the energy losses suffered by a charged particle while passing through a small volume. This study has extended these methods to calculating densities of such quantities as the energy deposited in the volume, the ionization produced there by the particle, or the ionization after multiplication in a proportional counter. The problem to be overcome was that while the possible increments to the energy-loss are the same everywhere along the track of the particle, the possible increments to the quantities mentioned differ from point to point along the track. Formulas were developed to allow for the point-to-point variation. It was also shown that if the correct average of the possible increments along the track of the particle were used, the same fast numerical methods developed for the energy-loss calculations can be used for the other quantities. Additional ionization data for protons passing at different distances from the center of a small volume have been obtained for 4 MeV protons. The limitations of the proportional counter technique for microdosimetry measurements were critically evaluated. The conclusion is that proportional counters will probably be limited to volumes larger than about 0.2 micrometer diameter sites. Measurements of the heat defect for 1.7 MeV protons on several materials were made using calorimetric techniques. Studies were completed for linear polyethylene, polystyrene, and polystyrene plus 20% carbon. A twin calorimeter was assembled and used for measurements of absorbed dose.

5.0957, INTERNAL DEPOSITIONS OF RADIONUCLIDES IN MAN

A.J. HAVERFIELD, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

These studies are concerned with the continued development and improvement of internal dosimetry of radiotoxic materials in man. Included are diagnostic techniques for assessment of internal depositions, interpretive methods for arriving at required dose estimates, modeling of anatomical features and physiological processes associated with the respiratory system, techniques for measuring quantities of radioactive pollutants in working environments, and maintenance of a program of evaluation of tissue specimens obtained postmortem from radiation workers and environmental residents.

In relation to human inhalation testing of promethium-143 oxide, an aerosol generator was designed, fabricated and tested. Particle size studies were performed to determine particle size distributions as a function of aerosol concentrations and other operation parameters. Promethium-147 and samarium-145 chloride were injected into rats for subsequent analysis after sacrifice to determine if gross differences exist in the metabolisms of these materials. An investigation of 'in vivo' detection of promethium-147 in humans was made utilizing phantoms. Measurement of a 0.12 MeV gamma ray which occurs 4x10 to the minus 5 of the time results in a minimum detectable activity of about 5 muCi in the lung. Analysis of bremstrahlung from promethium-147 resulted in a minimum detectable activity of about 1 muCi in the lung.

RESULTS. Investigation continued on methods of producing plutonium-237 at an appropriate purity for human testing application in establishing a quantitative relationship between body burden and excretion of plutonium-239 primarily in the presence of a standardized regimen of chelation therapy. Two irradiation sequences were completed, neither of which produced plutonium-237 of the desired purity. A plutonium tissue monitor was designed and a prototype built and tested in the morgue of the local hospital. The device is for use by the pathologists in screening autopsy cases for gross findings of plutonium in liver.

5.0958, MECHANISMS OF ENVIRONMENTAL EXPOSURE

J.F. HONSTEAD, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

The purpose of this study is to identify and measure parameters of exposure pathways in the Hanford environment utilizing the monitoring and other environmental data generated in evaluating Hanford environmental dose. The study selects population segments of unique interest because of their diets, habits, or location and performs whole- body counting and diet surveys. The body burden data and diet information together with environmental sample analyses permit calculation of dose contributions from various pathways and the means of evaluating the validity of such calculations.

A special dietary questionnaire was developed to study seafood consumption in typical seafood producing communities along the Washington and Oregon coasts. Radioactive Zn65 is transported. The questionnaire used colored photographs of weighed seafoods to assist volunteers in communicating typical consumption levels. This questionnaire was used to obtain seafood consumption data from nearly 500 residents of two seafood production centers on the Pacific Coast. The volunteers were also measured in a mobile wholebody counter to determine their Zn65 body burdens from seafood consumption.

An effort was made to calculate the body burdens of Zn65 from each person's estimate of seafood consumption and the measured body burden. From the results, it was apparent that Zn65 consumed in different kinds of seafood contributed different body burdens, i.e., different fractions of Zn65 appeared to be absorbed. A regression analysis was programmed so that the resulting regression coefficients would represent the fractional uptake of Zn65 from oyster, clams, crabmeat and shrimp, the four seafoods representing most of the Zn65 ingestion in the communities. After computing body burdens, the file was sorted to include only those individuals for whom the measured-to-calculated Zn65n body burden ratio was between 0.5 and 2.0. This included about half of the total population studied. Each time a new regression analysis changed the apparent uptake fractions, a new iteration and resorting of the file took place until the fractional uptake values converged. The values obtained from all subjects in both communities studied gave the fractional uptake of Zn65 from oysters of 1 percent, from clams of 10 percent, from crabmeat of 5 percent and from shrimp of 22 percent. The fractional uptake values are in the inverse order of (Text Truncated - Exceeds Capacity)

5.0959, INHALATION STUDIES - KINETICS AND DOSIMETRY STUDIES

J.F. PARK, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

This project is concerned with studies of the deposition, retention, translocation and excretion of inhaled, primarily alpha emitting, radionuclides including 239Pu, 238Pu, 244Cm, 242Cm, 241Am, 241Pu, and 147Pm. Aerosols of various particle sizes and physical and chemical properties are administered to rats and dogs. Data from these studies are used to develop models describing the tissue or organ radiation dose, especially to lung and lymph nodes, for hazard evaluation and for interpretation of observed pathological effects.

RESULTS. Tissue distribution data were obtained from dogs exposed up to 4 years previously to aerosols of 147Pm203, and from a number of dogs sacrificed up to 9 years following inhalation of 239Pu02. The plutonium data indicate that tracheobronchial lymph nodes may attain 60% of the initial alveolar deposit; liver burdens may reach 15 to 20% at times up to 15 years after exposure; skeletal burdens rise to 5 or 6%. The lung washing technique combined with autoradiography was used to study the distribution of plutonium in macrophages. Further studies on dose distribution from individual inhaled plutonium particles were carried out using a computer simulation technique.

SUPPORTED BY U.S. Atomic Energy Commission

5.0960, INHALATION STUDIES - THERAPEUTIC REMOVAL STUDIES

J.F. PARK, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

The objective of this project is to develop and evaluate effective therapeutic procedures for accelerating the clearance of inhaled radionuclides. Studies are conducted on rats and dogs.

RESULTS: Forty therapeutic agents were tested in continuing studies of the therapeutic removal of inhaled 239PuO2 from the lungs of rats. Promazine HCl, Diuril, Phenergan, Progesterone, Diamox and Miltown appear to show some effectiveness. When animals were treated with these drugs in combination with DTPA the primary drug treatment seemed to make inhaled super 239PuO2 more available for chelation by DTPA. Lung washing studies on rats indicate that pulmonary lavage is an effective method for removing plutonium from the lung. Studies were started using lung lavage to remove inhaled super 239PuO2 from dogs.

5.0961, INHALATION HAZARDS TO URANIUM MINERS - RADIOCHEMICAL STUDIES

R.W. PERKINS, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

To ensure that the composition of exposure material at the point of inhalation by an animal in biological studies is properly known and that its behavior in the animals subsequent to exposure is properly determined, it is essential that technology for characterization and measurement of the inorganic, organic, and radioactive exposure constituents be developed. If the results of the animal experiments are to be placed in proper perspective, the compositions of the aerosol and materials deposited in the respiratory system and other organs must be compared for the experimental animals and uranium miners. The objectives of this study are to provide detailed characterization of the inorganic, organic and radiochemical compositions of the atmospheres to which experimental animals are exposed; to determine uptake, retention, and translocation of the materials in experimental animals; and to compare these experimental conditions with the actual conditions of the uranium miners.

RESULTS: A procedure for the continuous direct measurement of radon daughter concentrations in uranium and in experimental animal chambers as a function of particle size employing both gamma-ray and alpha-particle spectrometry for air concentrations of RaA, RaB, RaC, and RaC' was developed. Radium-226 in animal tissues was determined utilizing a scintillation measurement of Rn-222 plus its alpha-emitting daughters, Po-218 and Po214. Neutron activation analysis procedures have been developed for the analysis of tissues.

SUPPORTED BY U.S. Atomic Energy Commission

5.0962, RADIOISOTOPES AS PARTICLES AND VOLATILES

G.A. SEHMEL, Battelle Memorial Institute, *Richland, Washington* 99352 (AT)

The objective of this work is to theoretically and experimentally determine the interaction of particles and vapors with surfaces. An improved understanding of particles and vapor interactions with surfaces will permit better estimates and interpretation of particle deposition and retention in ducts, tubes, surfaces in the open air, lung passageways samplers, and delivery lines. An objective is to establish through theory and experiments fundamental relationships among variables controlling deposition, and to develop models which correctly relate the variables. An attendant objective is to develop improved techniques and experimental methods for generating, sampling, characterizing and utilizing particles and radioactive gases and vapors.

Experimental particle concentration profiles above deposition surfaces are needed to check the validity of deposition model assumptions. Monodisperse uranine particles are used in wind tunnel studies to measure deposition velocities as a function of average air velocity, friction velocity, and particle size.

Results: Particle deposition velocities to the 0.7 cm high grass are nearly constant at 6 cm/sec for particle sizes from 6 to 16 mu m for a friction velocity of 70 cm/sec. For an increase in friction velocity to 144 cm/sec, the deposition velocity increases to 9 cm/sec. Particle eddy diffusion coefficients were estimated for the region less than 1 cm above the grass surface. The results show that effective particle eddy diffusivities must be much greater than those that can presently be predicted.

SUPPORTED BY U.S. Atomic Energy Commission

5.0963, RADIATION INSTRUMENTATION - RADIOLOGICAL CHEMISTRY

N.A. WOGMAN, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

The scope of the study includes the development of radiochemical instruments and analytical technology and their

application in radioisotope studies at very low levels and in special matrices encountered in environmental samples; the use of neutron activation analysis techniques in defining the stable element versus radioelement behavior in the environment; application of the methods of physical chemistry and radiochemistry to obtain detailed definition of the routes described by natural, tracer, or waste radioisotopes in environmental systems; and elucidation of chemical phenomena which determine the preferred routes.

RESULTS: An all sodium iodide anticoincidence shielded total absorption spectrometer designed for low-level radionuclide analyses was fabricated from a 34cm-diameter by 34-cm-thick NaI(Tl) ingot which surrounds an 18cm-diameter by 22cm-thick NaI(Tl) principal detector. The sensitivity of the system for single gamma-ray emitters is greater than that of any NaI(Tl) or Ge(Li) multidimensional gamma-ray spectrometer. The use of a large Ge(Li) diode inside a NaI(Tl) crystal provides an improved sensitivity for the measurement of most radionuclides which decay by emission of two or more photons.

5.0964, INVESTIGATIONS OF THERMOLUMINESCENT RADIATION DOSIMETRY

J.R. CAMERON, Univ. of Wisconsin, School of Medicine, *Madison, Wisconsin* 53706 (AT(11-1))

It is planned to continue our investigations in both the practical applications of thermoluminescent phenomena and the fundamental physical processes that may help us to better understand these phenomena. We plan to investigate new phosphors which might be useful for fast neutron dosimetry and we will also evaluate any new proposed commercial TLD phosphors to determine their dosimetry characteristics. Special effort will be made to develop an integrating fast neutron dosimeter using optical techniques on hydrogenous materials. We propose to study photoexcitation fluorescence, metastable exciton phosphorescence properties and photoconductivity resulting from fast neutron induced damage centers in a variety of promising hydrogen-rich solids. In addition we will use a laser to study neutron induced defect and impurity states in solids by the Raman effect. Materials to be studied include cyclic hydrocarbons, simple grouped organic solids and ammonium based solids. We will use new high intensity UV sources for some studies. We plan to continue our applications of thermoluminescence to UV dosimetry.

SUPPORTED BY U.S. Atomic Energy Commission

5.0965, THE VALUE OF RADIOPROTECTIVE COMPOUNDS

R.I. WANG, Marquette University, School of Medicine, *Milwaukee, Wisconsin* 53233

From the results of studying the cardiovascular effects and capillary permeability it can be concluded that a mixture of radioprotective compounds exert different mechanisms of action. The employment of this mixture containing (5-HT) 5-hydroxytryptamine, 2- aminoethylisothiouronium (AET) and 2- mercaptoethylamine (MEA) becomes scientifically justified.

In chronic irradiation the limiting factor of the chemical mixture continues to be the high incidence of chemical mortality.

Attempts will be made to reduce this toxicity by employing similar pharmacologically active compounds with less toxicity or by using pharmacological antagonists in the hope of reducing the toxicity without lowering the radioprotective effect. Study to reduce toxicity will also be made by using lower doses of each chemical against various doses of X-rays, even as low as 100 R, given at different intervals.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

5.0966, STUDIES OF PROBLEMS RELATED TO CHEMICAL PROTECTION AGAINST RADIATION

A. HASEGAWA, U.S. Veterans Administration, Center, *Wood, Wisconsin* 53193

The radioprotective effect of a chemical mixture containing 2 mg. of 5-hydroxytryptamine (5-HT), 28 mg of 2-aminoethylisothiouronium (AET) and 17 mg. of 2-mercaptoethylamine (MEA) was investigated in rats. The mixture was administered intraperitoneally 10 min. before whole body X- irradiation. Control rats received saline before irradiation. The LD50(30) of the chemically protected rats was 1580 R whereas the LD50 of control rats was 860 R. The dose reduction factor was 1.83. The protective effect of this mixture was greater than that of any of its components.

The cardiovascular effects of the above mixture and its components have been studied in anesthetized rats and mice in order to elucidate possible mechanisms of radioprotective action. In rats, 5-HT (2 and 4 mg) produced a depressor response. A low does (28 mg) of AET produced no change but a high dose (70 mg) resulted in a 23% increase in blood pressure. The response to MEA (17, 34, 46 mg) was varied. The chemical mixture produced a marked decrease in blood pressure. In mice, 5 HT(0.8mg) produced a pressor response when the initial pressure was low and a depressor response when the initial pressure was high. AET(2 mg) and MEA(2.9 mg) produced pressor responses. The chemical mixture also exhibited pressor effects.

DESCRIPTION OF RESEARCH TASKS

6. NOISE

A. AIR TRANSPORTATION

Sources Such As Airports, Airplanes, and Related Equipment

6.0001, SOUND PROPAGATION AND ATTENUATION CHARACTERISTICS OVER A HEAVILY VEGETATED TERRAIN

S.P. PAO, Wyle Laboratories, *Huntsville, Alabama* (DAHC04)

Technical objective: To establish a clear definition of the type of mesurements required in the field for evaluating the actual propagation loss due to real ground cover. When helicopters are operated over a heavily vegetated terrain, the noise produced does not propagate with the same intensity as it would over flat open land. Attenuation of the sound by the terrain is thus an important part of the problem of helicopter detection by noise. This aspect of noise is being studied by using inexpensive models in the laboratory and performing analyses predicting field behavior.

SUPPORTED BY U.S. Dept. of Defense - Army

6.0002, SMALL TURBINE ENGINE NOISE REDUCTION

R.N. TEDRICK, Garrett Corporation, *Phoenix, Arizona* 85034 (F33615-71-C-1457)

Technical Objective: The overall objective of this program is to develop the technology base necessary to effectively reduce the noise signature of existing small turboprop and turbofan engines to acceptable levels for low altitude reconnaissance/surveillance and special operations missions. In this program, emphasis is placed on the application of sound suppression and attenuation techniques rather than internal engine design changes.

SUPPORTED BY U.S. Dept. of Defense - Air Force

6.0003, PROGRAM TO REDUCE THE NOISE SIGNATURE OF THE OH-6A HELICOPTER

H.W. FERRIS, Hughes Tool Company, *Culver City, California* 90230 (DAAJ02)

Technical Objective: To obtain the maximum reduction in external noise level of the OH-6A helicopter within the constraints of time and money as imposed by this contract.

SUPPORTED BY U.S. Dept. of Defense - Army

6.0004, PREDICTION OF NEAR-FIELD NOISE FROM FIGHTER, TRANSPORT AND OTHER MILITARY CONFIGURED VTOL AIRCRAFT

L.C. SUTHERLAND, Wyle Laboratories, *El Segundo, California* 90246 (F33615-69-C-1407)

Technical Objective: The near field noise environment associated with VTOL vehicles operating in the hover mode is of sufficient severity to result in structural fatigue, equipment malfunction, and degradation in ground and flight crew performance. The predominant source of this noise is the propulsion system. Methods of predicting propulsion system noise are lacking when the aircraft is in close proximity to the ground. This program will evaluate military VTOL aircraft configurations relative to their near field noise environment and will develop methods to predict the noise characteristics required to estimate structural response and internal noise levels. These predictions will allow the design of lightweight sonic fatigue resistant structure and insure that adequate standards of habitability are met from the acoustic standpoint thus decreasing potential causes of excessive maintenance and insuring conformance of aircraft crew stations with standards of acceptable noise.

SUPPORTED BY U.S. Dept. of Defense - Air Force

6.0005, THEORETICAL ACOUSTICS

R.K. COOK, U.S. Dept. of Commerce, Environ. Research Laboratories, *Boulder, Colorado* 80302 (000180)

The principle objective is an improved determination of sound propagation through the real atmosphere, including the effects of winds, temperature gradients, turbulent eddies, and reflection and scattering. The results will lead to a better quantitative description of the pollution of the environment of unwanted sound and noise.

A manuscript now being prepared for publication on the 'total' reflection of a sonic boom by a water surface will summarize current theoretical researches.

Infrasonic apparatus is being assembled for a detailed study of microbarom sound waves on the eastern seaboard, at two stations about 70 miles apart. The data on microbaroms will be correlated with surface wave and meteorological conditions on the Atlantic Ocean, and will be complemented by an improved theory for the influence of winds on the propagation of microbarom waves.

Quantitative expressions have been found for the two 'infinitely' large spikes of sound pressure which are at the leading and trailing edges of a sonic boom reflected from a water surface. The infrasonic station at Gaithersburg, Md. has been refurbished, and is now in readiness to record the direction of propagation, horizontal phase velocity, and sound pressure amplitude of microbarom sound waves generated by surface waves on the Atlantic Ocean. A temporary station is being set up at Fredericksburg, Va.

SUPPORTED BY U.S. Dept. of Commerce - E.S.S.A.

6.0006, OPTIMIZATION OF AUDITORY PERFORMANCE IN NAVAL AVIATION

C.E. WILLIAMS, U.S. Navy, Aerospace Medical Res. Lab., *Pensacola, Florida* 32512

Technical Objective: Optimize auditory performance in various naval aviation acoustical environments and minimize or eliminate various problems arising from the many forms of interaction between sound and man in naval aviation e.g., noise masking of acoustic signals of importance to the naval aviatior (speech, sonar, auditory warnings), auditory fatigue due to prolonged exposure to various flight operation noises, etc.

SUPPORTED BY U.S. Dept. of Defense - Navy

6.0007, METROPOLITAN AIRCRAFT NOISE ABATEMENT STUDY (LOGAN INTERNATIONAL AIRPORT)

P.A. FRANKEN, Bolt Beranek & Newman Inc., *Cambridge, Massachusetts* 02138 (000384)

Develop useful alternatives for achieving both preventive and remedial relief from aircraft noise exposure in the vicinity of a large metropolitan airport - Logan International Airport,

Boston, Massachusetts. Included are considerations of: basic causes, growth trends, and social-economic impact of aircraft noise exposure on individuals and communities near airports. The project will include preparation of alternative approaches for use by local, state, and Federal governments to guide them in land use development, airport development, and related aircraft operational procedures.

Develop a methodology for use by other airport and metropolitan planning officials.

Revised draft report in review by Government.

Document provided to SIE by the Highway Research Information Service

SUPPORTED BY U.S. Dept. of Transportation - N.A.O.

6.0008, DEVELOPMENT OF QUIET ENGINES FOR NAVAL AIRCRAFT PROPULSION

H.J. ALLEN, Curtiss Wright Corporation, *Rutherford, New Jersey* 07075 (N00019-69-C-0460)

Technical Objective. Reduce vulnerability of Naval observation aircraft by reducing the amount of noise emitted from the engine. Evaluate noise-reducing features, continue analytical and technical search for a low noise engine, and define an optimum power plant configuration.

SUPPORTED BY U.S. Dept. of Defense - Navy

6.0009, INVESTIGATION OF GEARBOX DESIGN MODIFICATIONS FOR REDUCING HELICOPTER GEARBOX NOISE

R.H. BADGLEY, Mechanical Technology Inc., *Latham, New York* 12110 (DAAJ02)

Technical Objectives: Using a computer program and analyzing procedures developed under a previous program, this study to reduce helicopter noise will focus its efforts on the dynamic behavior of the rotating components within the transmission and the manner in which the housing itself interacts with them.

SUPPORTED BY U.S. Dept. of Defense - Army

6.0010, WHOLE-BODY EFFECTS OF AIR FORCE NOISE ON PEOPLE

C.W. NIXON, U.S. Air Force, Aerospace Med. Res. Lab. 6570, *Dayton, Ohio* 45433

Technical Objective: A wide range of intense Air Force noise environments not only effect hearing but may interfere with motor performance, physiological functioning, thought processes and contribute to fatigue in personnel. This effort investigates types of noises and exposure conditions in which accomplishment of the Air Force mission may be threatened because of these adverse whole-body effects. Results are used to formulate exposure limitations and establish specifications for Air Force activities responsible for assuring that personal noise exposures are nonhazardous.

SUPPORTED BY U.S. Dept. of Defense - Air Force

6.0011, MECHANISMS OF NOISE GENERATION, PROPAGATION AND RECEPTION AS RELATED TO AIR FORCE BIOACOUSTIC PROBLEMS

R.G. POWELL, U.S. Air Force, Aerospace Med. Res. Lab. 6570, *Dayton, Ohio* 45433

Technical Objective: Many USAF operations (e.g. aircraft on the ground and inflight, engine test stands, escape systems, auxiliary equipment) produce high noise levels in areas where man must function. These levels frequently cause serious problems concerning communication, hearing loss, annoyance and performance. This work unit provides: (1) knowledge and engineering methods necessary to calculate these environments, and (2) quantitative information on the physical mechanics involved in the generation of speech and man's response to acoustic energy

SUPPORTED BY U.S. Dept. of Defense - Air Force

6.0012, QUIET PROPELLER CONCEPT EVALUATION

P.A. SHAHADY, U.S. Air Force, Aerospace Propulsion Lab., *Dayton, Ohio*

Technical Objective: The objective of this program is to evaluate the noise characteristics of various tail rotor configurations to determine the noise reduction potential of various new designs. Variables to be investigated include number of blades, blade to hub phasing angles and blade length.

SUPPORTED BY U.S. Dept. of Defense - Air Force

6.0013, CONTROL OF HUMAN EXPOSURE TO ACOUSTIC ENERGY GENERATED BY AIR FORCE ACTIVITIES

H.C. SOMMER, U.S. Air Force, Aerospace Med. Res. Lab. 6570, *Dayton, Ohio* 45433

Technical Objective: To investigate all avenues of potential value for controlling personnel exposure in the wide variety of usual and unusual acoustic environs of Air Force operations, and to control, within acceptable limits, the intrusion of noise into residential areas neighboring on Air Force activities. The continuous growth of Air Force noise problems, currently reflected in higher levels of intensity and more frequent exposures, significantly increases exposure of persons in or near Air Force activities to possible adverse effects of the acoustic energy. This effort is to provide the principles, devices and procedures necessary to control, within safe and acceptable limits, human exposures to the many types of noise encountered in Air Force activities.

SUPPORTED BY U.S. Dept. of Defense - Air Force

6.0014, AIR CREW PERSONNEL NOISE EXPOSURE

J.V. TOBIAS, U.S. Dept. of Transportation, Civil Aeromedical Institute, *Oklahoma City, Oklahoma*

Relatively little work has been done on the effects of aircraft noise inside new aircraft. Information on the determination of noise levels in helicopters, for instance, is quite limited and on noise levels in helicopters used commercially, even less data are available. Except for some measurements made on manufacturers, relatively little has been done on the determination of noise levels within cabins of commercial transport aircraft. Similar statements are true of general aviation aircraft. Further, although available measurements are reliable and accurate, they are frequently not as complete and thorough as might be desired, probably because the necessary analyzing equipment is not readily available. However, such data are important in the delineation of possible fatigue problems among people who fly regularly either as new crew members or as passengers. Further work is necessary to record noise levels in new and modified aircraft.(Text abridged)

SUPPORTED BY U.S. Dept. of Transportation - F.A.A.

6.0015, ACOUSTIC INTERFERENCE WITH COCKPIT COMMUNICATIONS

J.V. TOBIAS, U.S. Dept. of Transportation, Civil Aeromedical Institute, *Oklahoma City, Oklahoma* (000605)

In difficult transmission conditions, speech is often degenerated to the point of nearly complete unintelligibility. Particular problems arise during IFR conditions: the communication interference as a result of the weather may increase and the importance of correct interpretation of ATC instructions is simultaneously increased.

Normal communications - channel noise (AM, FM, and ambient) will be investigated for influence on speech intelligibility. These degenerated and masked signals will then be reinvestigated for relative intelligibility under several schemes of transmission improvement. Multiplex FM, infinite peak clipping, quantizing, differentiating, etc., will be used, and the best will be incorporated into an experimental system. The experimental series thus is designed to develop and evaluate a system which will transmit speech more intelligibly under a variety of adverse conditions.

Tests are nearly complete on the masking effects of noises comprising interrupted tones. Some delay was experienced in performing these tests because subjects who were originally exposed to the situation were unable to give accurate data. Several independent underlying causes were found and ultimately corrected. It is now practical to use the technique for determining the masking effectiveness of any signal that might serve to degenerate the quality of important transmissions. A report on the basic work leading to the development of this testing system will be prepared as soon as the final few data are collected. The rest of the experiments proposed will now be undertaken and should be relatively simple to complete.

Document provided to SIE by the Highway Research Information Service.

SUPPORTED BY U.S. Dept. of Transportation - F.A.A.

6.0016, INVESTIGATION OF HELICOPTER TRANSMISSION NOISE REDUCTION BY VIBRATION ABSORBERS, DAMPING AND CASE DESIGN

H. STERNFELD, Boeing Company, *Philadelphia, Pennsylvania* (DAAJ02)

Technical Objective: Conduct design studies to determine the relative effectiveness of different methods of noise attenuation as they apply to the CH-47 helicopter forward transmission noise.

SUPPORTED BY U.S. Dept. of Defense - Army

6.0017, INVESTIGATION OF NOISE GENERATION ON A HOVERING ROTOR

H. STERNFELD, Boeing Company, *Philadelphia, Pennsylvania* (DAHC04)

Technical Objective: To define the noise field generated by a rotor. Investigation of noise generation of a helicopter rotor is important for the army's effort to make its helicopters less noisy for more effective field operations. This research is important to the army in that it represents a long range effort to reduce army aircraft detection time.

SUPPORTED BY U.S. Dept. of Defense - Army

6.0018, INVESTIGATION OF LOW SPEED AERODYNAMICS AND NOISE GENERATION MECHANISMS FOR DESIGN OF QUIET RECONNAISSANCE AIRCRAFT

R. KROEGER, Univ. of Tennessee, School of Engineering, *Knoxville, Tennessee* 37916 (F33615-70-C-1762)

Technical Objective: From a military standpoint it is desirable that aircraft operate in such a way as to avoid detection. One means by which aircraft are detected is by the noise they generate and propagate to a receiver. The primary noise associated with aircraft is emitted from the propulsion system and from sources associated with the aircraft in flight. Within aircraft performance limitations, the propulsion system noise can be controlled. When these sources are minimized, the noise associated with flight then becomes the dominate factor in aural detection. The objective of this effort is to conduct an investigation of the noise associated with flight and determine methods of suppressing the noise radiated from these sources. These methods will be incorporated into design information required to design an aircraft from the standpoint of minimum aural detection for covert reconnaissance operations.

SUPPORTED BY U.S. Dept. of Defense - Air Force

6.0019, ENGINE AND PROPELLER NOISE

L.K. LOFTIN, U.S. Natl. Aero. & Space Adm., Langley Research Center, *Hampton, Virginia* 23365

The objectives of this work are accomplished by the following: (A) Identification and evaluation of the sources of noise that are significant under various operating conditions of jet engines (including exhaust jets, fans, compressors, and turbines) and propellers (with and without ducts), with a view toward noise reduction at the source by design. Such factors as jet velocity, temperature, density, and turbulence level; tip speed, number of blades, inflow angles, section characteristics, surface roughnesses wake interactions, etc. for propellers, fans, compressors, and turbines will be studied to determine their effects on the generated noise; (B) Noise reduction by means of the application of acoustic materials in the inlet, in the fan discharge ducts, in the main exhaust duct of an engine or by the application of jet exhaust noise suppressor; (C) Identification and evaluation of those factors significant in the attenuation of noise during propagation from air to ground or from ground to ground situations; (D) Development of adequate methods of prediction of noisespectra from aircraft power plants under various operating conditions and at various distances. This work will be accomplished by means of theoretical studies, by full- scale aircraft tests and by model tests in wind tunnels and special test cells. The investigator shown above is the Project Monitor whose telephone is 703-827-3285.

SUPPORTED BY U.S. Natl. Aero. & Space Adm.

6.0020, TURBOFAN

L.K. LOFTIN, U.S. Natl. Aero. & Space Adm., Langley Research Center, *Hampton, Virginia* 23365

Problem- To develop acoustic treatment designs for reducing the turbine noise and turbulence generated noise radiated from a jet engine tailpipe. Application- Although the acoustic treatment will be tailored to a specific engine, the design criteria will be presented in general terms so that it can be applied to current and future technology commercial fanjet engines. Approach- Contract for the design and development of an acoustically treated tailpipe for ground tests on a JT3D engine. Conduct noise measurements and engine performance analysis. The investigator shown above is the Project Monitor whose telephone is 703-827-3285.

SUPPORTED BY U.S. Natl. Aero. & Space Adm.

6.0021, PSYCHOACOUSTIC ASPECTS OF AIRCRAFT NOISE AND SONIC BOOM

C.H. NELSON, U.S. Natl. Aero. & Space Adm., Langley Research Center, *Hampton, Virginia* 23365

The objective of this work is to further the understanding of psychological and physiological effects of noise, to establish techniques for measuring subjective noise factors, and to apply psychoacoustic information to minimize the potential annoyance of noise on man by modifications of the noise characteristics. Studies will include subjective noise comparison tests, absolute judgement tests, sleep interference tests, auditory and non-auditory tests, startle tests, task performance tests, and acoustic-vibration tests. The tests will be accomplished in laboratories and under real life conditions of exposure to aircraft noise during flight. Special attention will be directed to bridging the gap between the flight exposure situation and laboratory tests. The tests will be complemented by survey studies (involving social, economic, and atttudinal factors) and by special analytical programs. The data obtained will be used to develop an information base having application to establishing international noise standards, to prediction of public reactions to future aircraft/airport operations, and to the evaluation of aircraft noise reduction approaches. The investigator shown above is the Project Monitor whose telephone is 703-827-3285.

B. SURFACE TRANSPORTATION

Trains, Automobiles, Tractors, Buses, Trucks, and Highway Noise in General

6.0022, IMPACTS AND ALLEVIATION OF TRANSPORTATION NOISE

R. HORONJEFF, Univ. of California, School of Engineering, *Berkeley, California* 94720 (000658)

Make specific contributions to existing knowledge about the impact of transportation noise on community, physical, social, and economic environment; further explore methods for reducing transportation noise by analyzing their effectiveness, impact on system performance, cost, feasibility, and economic desirability;

provide urban planners, transportation system planners and operators, acousticians, governmental agencies and others with better measures of the community cost of transportation noise, and with better techniques for noise alleviation.

Document provided to SIE by the Highway Research Information Service.

SUPPORTED BY U.S. Dept. of Transportation - N.A.O.

6.0023, STUDY OF THE NOISE PRODUCED BY TRANSPORTATION EQUIPMENT, DEVICES POWERED BY INTERNAL COMBUSTION ENGINES - STUDY OF COMMUNITY NOISE

K. ELDRED, Wyle Laboratories, *El Segundo, California* 90246 (68-04-0046)

As many sources of noise as possible will be identified and their current noise levels defined. In reporting the noise levels measured, the following information will be included: (1) Actual geometry of microphone placement (including directionality effects). (2) Sound pressure levels in 1/3-octave bands (if available) or octave bands. Reduction of spectral data to dB(A) and where possible data indicating attenuation of sound pressure level with distance. (3) Typical operating exposure (who, where, when, how long).

The human related problems associated with the subject noise sources will be identified. The coverage will be in the form of indicating the typical effects of noise. Where possible, the groups or organizations responsible for initiation of the noise abatement programs, i.e., government, industry labor organization, consumer, etc. will be identified.

The state-of-the-art of the application of noise abatement technology to the subject sources of noise will be assessed and trends will be identified. Existing noise standards and/or specifications relating to sources will be compiled. This reported information will include: (1) Reduction levels being achieved or anticipated in present programs. (2) Methods of approach. (3) Program pay offs. (4) Plans for further reduction of noise. (5) Determination of what noise reduction can be demonstrated on equipment for which minimal or no noise reduction technology is presently being applied.

A study of the total nature of community noise to determine the kinds of noise in the community and its effect.

SUPPORTED BY U.S. Environ. Protect. Agency - O.N.A.C.

6.0024, TRAFFIC NOISE NEAR HIGHWAYS AND THE EFFECTS OF DESIGN AND ENVIRONMENTAL VARIABLES

J.B. SKOG, State Div. of Highways, *Sacramento, California* 95814 (2R52082722)

The effects of design and environmental variables are being determined on the emanation of traffic noise from highways. Measurements are being made at discrete distances from highways in flat terrain, depressed section and elevated section. Other tests are being made in complaint areas involving special situations.

Document provided to SIE by the Highway Research Information Service.

SUPPORTED BY U.S. Dept. of Transportation - F.H.A.

6.0025, RAPID TRANSIT DESIGN & OPERATION STUDIES

UNKNOWN, San Fran. Bay Area Tran. Dist., *San Francisco, California* 94103 (000036)

Tests of equipment and facilities for the new BART system including sound and wind vibration reduction, propulsion and power supply etc. The end product is recommended design and construction criteria.

Document provided to SIE by the Highway Research Information Service.

SUPPORTED BY U.S. Dept. of Transportation - U.M.T.A.

6.0026, ESTABLISHMENT OF STANDARDS FOR HIGHWAY NOISE LEVELS

CLARK, Bolt Beranek & Newman Inc., *Van Nuys, California*

Acceptable ranges of highway noises are being developed to serve as a basis for adoption of standards. Those features of total highway and landscaping design are being determined which contribute significantly to the propagation or reduction of highway noise and a highway noise design guide (handbook) will be prepared for the highway engineer.

Document provided by Highway Research Information Service.

SUPPORTED BY U.S. Dept. of Transportation - Public Rds.

6.0027, NOISE ABATEMENT PROBLEMS

H.E. WEIHMILLER, Unknown Inst. Or Indiv. Grant, *District of Columbia* (000079)

Document provided to SIE by the Highway Research Information Service.

6.0028, TIRE SOUND GENERATION INVESTIGATION

J.F. HALLDANE, U.S. Dept. of Commerce, Natl. Bureau of Standards, *Washington, District of Columbia* 20234

Objectives: To determine through a study of tire sound generation whether the variations between tires can lead to an effective acoustical grading of tires. The project will be concerned with two areas of investigation: (a) the physical distribution and characteristics of sound generated by a representative range of commercial tires under various conditions, (b) a comparative assessment of the auditory responses to typical noises generated by tires.

Approach: A literature search will be conducted as well as a survey of the state-of-the-art in tire sound evaluation by visits to appropriate personnel and facilities. To determine the technical feasibility for a tire acoustical grading and auditory assessment program, a pilot study will be conducted by the Psychophysics Section of the National Bureau of Standards. Typical tire noises shall be taped and later compared both physically and psychophysically.

6.0029, SELECTION AND DEVELOPMENT OF ANTI-SKID SURFACES

PAREY, Lab. Cent. Des Ponts Chaussees, *Paris, France* (002415)

Following the program of measurement on existing surfaces, the research is now extended to the following problems: (1) Cement concrete surfaces on new roads by roughening treatments transverse or otherwise - giving acceptable noise and good roughness on existing roads by improvement by roughening by special coatings. (2) Asphaltic concrete surfaces - compositions which will be favorable to a satisfactory roughness and will be durable, and (3) Surface coatings - characteristics required of the binder, the aggregate and the laying.

SUPPORTED BY French Government

6.0030, NOISE AND VIBRATION OF OFF-ROAD EQUIPMENT

R.R. YOERGER, Univ. of Illinois, Agricultural Experiment Sta., *Urbana, Illinois* 61801 (ILLU-10-0327)

OBJECTIVE: Understand the mechanism of noise generation, structural transmission, and emission and the inter-relationship between design and operating parameters for the major contributors to the operational noise level of agricultural and industrial equipment and study the vibrational response of off-road vehicles and resulting operator environment when subjected to periodic and random inputs.

APPROACH: Consideration will be given to the functional components making major contributions to the sound power level of engine powered prime movers in an attempt to attenuate the sound as near to the source as possible. Exhaust, fan, structural, mechanical and intake noise are the major sources. A study of the mechanism of air movement under the conditions and general limitations of the engine cooling environment is to be undertaken. An analytical model of an exhaust system, considering the expan-

sion chamber as the primary noise reducing element, which can be used to predict noise attenuation, back pressure, flow profiles, and properties of the exhaust gases for given input conditions considering both steady and unsteady flow.

6.0031, TRAFFIC NOISE

UNKNOWN, Acoustic Society of Japan, *Tokyo, Japan* (2R52065214)

A method of estimating traffic noise under various traffic and road conditions is to be developed.

Document provided to SIE by the Highway Research Information Service.

SUPPORTED BY Japan Public Highway Corporation

6.0032, VENTILATION, ILLUMINATION, AND NOISE CONTROL IN TUNNELS

H. DATE, Japanese Ministry of Constr., *Tokyo, Japan*

Field tests and model tests in a laboratory will be conducted on ventilation, illumination and noise control which are special problems, in vehicular tunnels. Fundamental data will be obtained for rational scheme and design of tunnels.

Document provided by Highway Research Information Service.

SUPPORTED BY Japanese Government

6.0033, TRAFFIC NOISE

A. KANAIZUMI, Japanese Ministry of Constr., *Tokyo, Japan*

Noise levels of motor vehicle traffic, the relation between the noise and the type of pavement will be studied. The improvement of road design for better noise reduction will be developed.

Document provided by Highway Research Information Service.

SUPPORTED BY Japanese Government

6.0034, THE EFFECT OF A TUNNEL COVER ON SOUND ABSORPTION IN THE TUNNEL

UNKNOWN, Japanese Technical Development, *Tokyo, Japan*

The side wall of a tunnel is being covered with acoustic insulation to absorb the loudness of traffic noises. Its effectiveness is to be measured with before and after studies.

Document provided by Highway Research Information Service.

SUPPORTED BY Japan Public Highway Corporation

6.0035, A STUDY FOR RESEARCH AND REPORTING ON MASS TRANSPORTATION SYSTEMS (SUBWAYS) ACOUSTICAL ENVIRONMENT

P.A. FRANKEN, Bolt Beranek & Newman Inc., *Cambridge, Massachusetts* 02138 (000383)

Perform a study by reviewing available technical reports on the mass transit rail systems now in existence in foreign cities such as Toronto, Hamburg, London, Berlin, Paris, and Rotterdam. Select seven systems that appear to have the lowest noise levels. Make acoustical measurements and studies of these systems so as to complement existing data and provide additional data necessary to present a complete matrix of the acoustical environment. Analyze the results of the studies and tests and identify the parameters that define the systems acoustical environment. Rank the systems studied.

Document provided to SIE by the Highway Research Information Service.

SUPPORTED BY U.S. Dept. of Transportation - N.A.O.

6.0036, POLLUTION OF MICHIGAN URBAN ATMOSPHERES BY HIGHWAY GENERATED NOISE

P. MILLIMAN, State Dept. of Highways, *Lansing, Michigan* (2R52206494)

A study will be conducted to determine and characterize the sound spectra of highway noise. Experiments to validate the repeated correlation between the Zwicker method and human subjective response are to be conducted. Sound barriers are to be constructed using available materials and configurations to measure their effectiveness as absorbers and deflectors of highway generated noise. A computer program will be developed to predict the noise spectrum radiated from the highway under any given set of known conditions.

Document provided to SIE by the Highway Research INformation Service.

SUPPORTED BY U.S. Dept. of Transportation - F.H.A.

6.0037, TREES AND SHRUBS FOR NOISE ABATEMENT

D.I. COOK, Univ. of Nebraska, School of Engineering, *Lincoln, Nebraska* 68508 (WO1503)

OBJECTIVE: Determine reduction in highway traffic noise by tree and shrub barriers, most effective placement, pattern and density of vegetation to reduce sound, and whether sound transmission can be used as quantitative measure of windbreak density.

APPROACH: Study traffic noise transmission adjacent to and behind tree and shrub barriers. Record traffic noise for playback and analysis under varied environmental conditions and with various tree and shrub barriers. Test sound reduction by various types of belts as affected by season, species used, and belt density. Compare sound transmission with wind velocity data to determine whether a useful correlation exists for prediction of one effect by other. Develop recommendations for traffic noise abatement plantings.

PROGRESS: Studies of noise from trucks, buses, and automobiles show that trees can reduce noise up to 50 percent when used as a screen between highway and listener. No significant differences were noted between belts of different species compositions when height and density were similar.

SUPPORTED BY U.S. Dept. of Agriculture

6.0038, OPERATOR COMFORT, HEALTH AND SAFETY IN MOBILE AGRICULTURAL OPERATIONS

G.W. STEINBRUGGE, Univ. of Nebraska, Agricultural Experiment Sta., *Lincoln, Nebraska* 68508 (NEB-11-025)

OBJECTIVE: Obtain information pertaining to effect of present mobile agricultural equipment upon comfort, health & safety of operator; evaluate new developments with respect to operator comfort, health & safety and determine effect on humans of new designs; determine principal causes of accidents and make suggestions with regard to safety; develop criteria for future design of mobile agricultural machines.

APPROACH: Tabulate information from various sources to determine specific causes of tractor tipping accidents. Determine significance of tractor forward motion during a sideways upset. Devise a static upset procedure for experimental upsets of tractors. Experimentally upset tractors to secure data and establish criteria of design or operation which will tend to decrease such upset possibilities. Develop test procedures with which to evaluate upset stability of new tractors.

PROGRESS: Four tractor cabs were tested for their ability to withstand the side impact Swedish pendulum test and three tractor cabs were tested for rear impact resistance as provided in the Swedish pendulum test. Results of these tests indicated that deflections of the cabs tested were well within the limits set by the Swedish standards, the English standards, and the proposed SAE-ASAE American standards. One tractor with cab similar to those used in the pendulum tests was upset sideways in static roll-over down a 13 ft. high embankment of 3 to 2 slope and the movies of the upset compared with movies taken of the pendulum tests. Results of the comparison showed the cab had to withstand greater force and deflection in the actual roll-over than in the pendulum test. This comparison throws some doubt as to the adequacy of the proposed standards when applied to the cabs used on large American tractors. Noise tests were begun for the purpose of establishing the adequacy and dependability of the procedure to be used in determining the sound pressure levels of tractors tested at Nebraska. Experiments were also begun for

determining the possibility of using an air screen as a tractor cab for noise and temperature control for the tractor operator. A tabulation of tractor tipping accidents in Nebraska was continued. Results were essentially the same as in previous years.

SUPPORTED BY U.S. Dept. of Agriculture

6.0039, COLLECTION, PROPAGATION, CULTURE AND EVALUATION OF PLANT MATERIALS
J.O. YOUNG, Univ. of Nebraska, School of Agriculture, *Lincoln, Nebraska* 68503

This is a research project for the collection, propagation, culture and evaluation of plant materials for windbreaks, snow control, noise abatement, traffic guidance and control of glare for safety and landscaping on highway rights of way.

SUPPORTED BY U.S. Dept. of Transportation - Public Rds.

6.0040, SUPPORT OF SOCIETY OF AUTOMOTIVE ENGINEERS, INCORPORATED, NOISE RESEARCH STUDY
F.C. WALTERS, Soc. of Automotive Engrs. Inc., *New York, New York* (000386)

Obtain data which is correlatable to urban noise levels for use in transportation noise abatement research. This program is to gather, catalog, analyze and summarize available noise data in 3 areas relative to noise associated with the operation of tractors and related equipment. Specifically, the 3 areas are: (1) Definition of the physical characteristics of typical noises to which operators of such equipment might be exposed. (2) The tolerance levels of such operators, both with and without protection. (2) Degree of possible hearing damage and operator disorientation from exposure to variable noise.

6.0041, EFFECTS OF DIFFERENT FOREST TYPES AND CONDITIONS ON STREAM REGIMEN AND WATER YIELDS
R.E. LEONARD, State University of New York, School of Forestry, *Syracuse, New York* 12224 (NE1604)

OBJECTIVE: Determine the influence of climatic, edaphic, and other environmental factors on hydrologic processes in relation to forest types and conditions.

APPROACH: This cooperative project with the New York State University College of Forestry is determining the reflection of solar radiation by a conifer forest; conducting a study of snow interception by coniferous tree crowns and its disposition under climatic conditions of central New York; and the effect of land-use changes on streamflow in the Allegheny Plateau Region of New York State.

PROGRESS: Approximately one-half of the precipitation falling on the forested areas of the Northeast is returned to the atmosphere by the process of evapotranspiration. The major source of energy for this process is solar radiation. A study of the energy relationships in a northern hardwood forest revealed that a 50 year old second growth forest absorbs 83 to 87 percent of the incident radiation in the summer months and 73 to 80 in the leafless winter months. Snow on the ground decreased the absorption to about 73 percent of the total solar energy available at the top of the canopy. Results from this investigation will be useful in management considerations of forest type changes on drainage areas. In an exploratory study of noise abatement by trees, it was found that approximately 8 decibels of noise was absorbed in three 30-meter wide strips of a pine plantation. This excess attenuation was dependent on frequency and location of the sound source relative to the orientation of the rows of trees. This information will be useful in assessing the use of trees to screen out unwanted sounds.

SUPPORTED BY U.S. Dept. of Agriculture

6.0042, TRAFFIC NOISE STANDARDS
E. JONSSON, Natl. Swedish Inst. Bldg. Res., *Stockholm, Sweden*

Object: This investigation aims at finding, by measuring reactions of inconvenience, a basis for establishing standards for permissible exposure to traffic noise.

The field work was carried out in two stages. In the first stage 59 areas were chosen, which were different according to factors related to the noise exposure. In these areas were carried out noise exposure measure, based upon technical measurements, and a reaction measure, based upon interviews. Characteristics of the road, the area and the dwelling were measured and classified. A second stage contains a mapping of the noise situation in five larger development areas.

The result is certain findings according to exposure and reaction and the arrangement in the development. The investigation has been submitted to the National Boards, whose responsibility it is to issue standards.

C. URBAN AND INDUSTRIAL SOURCES

Includes Construction, Factory Noise, Home Environment, and Office Noise.

6.0054, WIND SENSING

C.G. LITTLE, U.S. Dept. of Commerce, Wave Propagation Laboratory, *Boulder, Colorado* 80302

Determine the ambient noise and noise pollution levels of an operational prototype acoustic doppler radar system, capable of measuring wind and turbulence profiles in the planetary boundary layer. The system will be demonstrated in Boulder, Colorado, to determine the feasibility of its use in urban areas, for engineering modification to minimize noise pollution, and for determining optimum system configurations.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

6.0055, THE DETERMINANTS OF REAL ESTATE VALUES

D.M. GRETHER, Yale University, Graduate School, *New Haven, Connecticut* 06520

The basic objective of this research is the estimation of the effect on housing value of location and of various 'neighborhood effects.' Here, 'neighborhood effects' include tax burden, quality of public services including education facilities, and air and noise pollution.

Data made available by the New Haven Board of Realtors make it possible to estimate the evaluation by home buyers of various physical characteristics. The available information includes asking and selling price of each property, the length of time the house is on the market, the lot size, the size of the house in square feet, the number of rooms, the condition of the house, the type of flooring, the type of building material, type of heating, type of electrical system, and considerable detail on such extras as air conditioning, rugs, laundry facilities, and so on.

The data will enable the analysis of a number of questions unrelated to the characteristics of the houses, with excellent control for variation in the quality of the housing units. For example, in assessing the impact of air pollution on residential property values, it is crucial to know if the quality of homes in areas of heavy pollution is higher or lower than the quality of homes in other areas.

The effects of heterogeneity of land use (zoning) can also be investigated. In addition, it may be possible to determine whether blacks pay more for housing of comparable quality, and to what extend financing arrangements inflate the price of housing for low income groups.

SUPPORTED BY U.S. National Science Foundation

6.0056, PLANNING STANDARDS FOR APPLICATION WITH THE LAND USE ACTIVITY ALLOCATION MODEL (LUAAM)

UNKNOWN, East West Gateway Coord. Coun., *East Saint Louis, Illinois* 62201 (002977)

In this analysis, the residential densities from the living patterns study were translated into holding capacities for use in the land use activity allocation model. The holding capacities for the activity allocation model are the suggested minimum and maximum number of people or employees which could be accommodated in each zone. The development of the maximum and minimum holding capacities and any necessary adjustments that were deemed desirable were based upon local agency studies and knowledge of a particular zonal area and its growth factors. Growth impact factors are concerned with the effects on the physical environment such as existing parks, vacant land, and developed areas. In an attempt to understand the effects of growth on a zone, the analysis was concerned with the general findings for the following items: (1) The good quality homes and businesses that would be displaced by growth. (2) The land area that would be required for new transportation facilities. (3) The effects of heavy traffic on existing business districts. (4) Byproducts of growth such as pollution and noise. (5) The maintenance of basic neighborhood integrity within a zone. The results of the previously mentioned studies were the maximum acreage, density, number of employees, and population for each zone.

6.0058, STUDY OF NOISE PRODUCED BY CONSTRUCTION EQUIPMENT AND BUILDING EQUIPMENT AND HOME APPLIANCES

E. BENDER, Bolt Beranek & Newman Inc., *Cambridge, Massachusetts* 02138 (68-04-0047)

As many sources of noise as possible will be identified and their current noise levels defined. In reporting the noise levels measured, the following information will be included: (1) Actual geometry of microphone placement (including directionality effects). (2) Sound pressure levels in 1/3-octave bands (if available) or octave bands. Reduction of spectral data to dB(A) and where possible data indicating attenuation of sound pressure level with distance. (3) Typical operating exposure (who, where, when, how long).

The human related problems associated with the subject noise sources will be identified. The coverage will be in the form of indicating the typical effects of noise. Where possible, the groups or organizations responsible for initiation of the noise abatement programs, i.e., government, industry, labor organization, consumer, etc. will be identified.

The state-of-the-art of the application of noise abatement technology to the subject sources of noise will be assessed and trends will be identified. Existing noise standards and/or specifications relating to sources will be compiled. This reported information will include: (1) Reduction levels being achieved or anticipated in present programs. (2) Methods of approach. (3) Program pay offs. (4) Plans for further reduction of noise. (5) Determination of what noise reduction can be demonstrated on equipment for which minimal or no noise reduction technology is presently being applied.

6.0060, MANAGEMENT AND CONTROL OF URBAN NOISE

D.P. LOUCKS, Cornell University, School of Civil Engineering, *Ithaca, New York*

No summary has been provided to the Science Information Exchange.

SUPPORTED BY Resources for Future Inc. - Wash., D.C.

6.0061, ENVIRONMENTAL INFLUENCES ON BEHAVIOR

D.C. GLASS, New York University, Graduate School, *New York, New York* 10003

Life in an urban metropolis has not only become increasingly complex, but there is also growing evidence of serious physical and psychological health hazards in the city. We know something of air and water pollution, but we know little about the hazard potential of noise and overcrowding, and the consequences of

these factors. One of the aims of the project is a systematic exploration of the effects of these physical-environmental stressors on individual and social behavior. More specifically, it is concerned with cognitive, interpersonal, and psychophysiological consequences of adaptation to noise and crowding. Parelleling this effort in the physical environment will be research into the psychosocial environment, including experimentation on feelings of control or lack of control over the environment. These research activities will take two forms: (1) theoretical, leading to the preparation of a monograph on models of psychological stress, specifically urban stress; and (2) empirical, consisting of a series of laboratory experiments on the issues described above.

SUPPORTED BY Russell Sage Foundation - New York, N.Y

6.0062, BARRIERS FOR NOISE ATTENUATION
J.N. MACDUFF, Duke University, School of Engineering, *Durham, North Carolina* 27706

An experimental and theoretical study of the usefulness of barriers and lightweight panels in attenuating the noise generated by industrial machines is proposed. The design, construction, measurement and evaluation of movable noise attenuating barriers will be undertaken. The types of barriers to be investigated will be such as could be used to (1) partially enclose a work space on the factory floor for personnel such as timekeepers, foremen, etc.; (2) be placed adjacent to machines in either a horizontal or vertical orientation to reduce the noise reaching areas by direct or secondary transmission.

The initial studies will be made with pure tones and rather small, rigid barriers. Barrier configuration, the effect of sound absorbing facing and of interior cavities will be studied. The pure tone experimental work will be paralleled by analytical studies. In this phase it is planned to investigate the feasibility of the finite element methods as a means of predicting noise levels in enclosed spaces.

6.0065, EFFECT OF ULTRASONIC ENERGY ON AQUATIC PLANTS
P.G. BARTELS, Univ. of Arizona, Agricultural Experiment Sta., *Tucson, Arizona* 85721 (ARZT-2014-4159-003)

OBJECTIVE: Determine effect of ultrasound on morphology, physiology, and membrane permeability of various species of aquatic plants; determine relative differences in above effects as a function of frequency, intensity, and time of exposure to ultrasonic waves.

APPROACH: Several species of aquatic plants will be subjected to ultrasonic waves and examined microscopically for morphological changes in cells and their inclusions. Respriation and photosynthetic rates will be measured using standard Warburg manometric techniques and infrared gas analyzer techniques. Permeability changes in membranes will be studied using standard radioisotope absorption techniques. A variable frequency ultrasonic generator and various piezoelectric transducers will be used to vary frequency and intensity of ultrasonic waves. Exposure times also will be varied.

PROGRESS: We have been investigating the effects of ultrasound on the ultrastructure of plant cells. In the past, we have used the plant Chara as the experimental plant to sonicate since they are very susceptible to this treatment. Currently, we are doing similar experiments with Potamogeton and Elodea, which are two common aquatic weeds causing many problems in the U.S. waterways. The chloroplasts were found to be the first organelle of the plant cell which appears injured. The fret or large thylakoid membranes become disrupted and with continued ultrasonic treatment, the grana membranes are destroyed. Another symptom of the ultrasound treatment is the swelling of the fret and grana membranes. In addition, Mr. Sidlowski is building some new ultrasonic lenses in order to focus high intensities of radiation on to an area where the plants will be positioned. In constructing these lenses, several characteristics must be considered. First, the acoustic impedence of the lens material and the medium should be matched as closely as possible. The most convenient material that we used was plexiglass or polystyrene.

6.0066, THE EFFECTS OF GRAVITY COMPENSATION, RADIATION AND MAGNETIC FIELDS ON LIVING ORGANISMS
C.A. TOBIAS, Univ. of California, Lawrence Radiation Laboratory, *Berkeley, California* 94720 (W-7405-ENG-48)

These studies aim to measure possible synergistic effects between gravity compensation and radiation on developing organisms. In addition, separate investigations will study relationships between effects of ultrasonic vibrations and radiations. The results are expected to be of value in interpreting biological effects of space environment; for example, the apparent synergism obtained between radiation and weightlessness in Biosatellite II. The results may also be of value in considering the radiobiology of tumor cells.

Results: Construction was completed on a monochromatic, ultrasonic vibrator to be used in biological studies. Exposures can be made at various power levels and frequencies in the domain of 0.1 to 5 MHz. Intensity distribution of the instrument in the vibration exposure field was calibrated with a piezo-electric instrument and is routinely monitored by means of thermocouples.

SUPPORTED BY U.S. Atomic Energy Commission

6.0067, THE EFFECTS OF GRAVITY COMPENSATION, RADIATION AND MAGNETIC FIELDS ON LIVING ORGANISMS
C.A. TOBIAS, Univ. of California, Lawrence Radiation Laboratory, *Berkeley, California* 94720 (W-7405-ENG-48)

These studies aim to measure possible synergistic effects between gravity compensation and radiation on developing organisms. In addition, separate investigations will study relationships between effects of ultrasonic vibrations and radiations. The results are expected to be of value in interpreting biological effects of space environment; for example, the apparent synergism obtained between radiation and weightlessness in Biosatellite II. The results may also be of value in considering the radiobiology of tumor cells.

Ultrasonic vibration studies are carried out on a variety of biological systems with specially constructed monochromatic generators. Earlier this laboratory identified the ultrasonic component as having the greatest biological effects at the cellular level than sonic vibrations. Mammalian cells have been used.

Results: Microscopic examination shows disruption of cells at high intensities and a shrinking of cells at low intensities. The lethal effects which are dose-rate dependent, are observed only in the presence of liquid medium during sonication. No lethal effects are observed if cells are sonicated in the 'frozen state'. Cells that survive heavy doses grow at a slower rate as indicated by their smaller colony size. Dose-fractionation studies show that prior ex-

posure to ultrasound sensitizes the cells to a subsequent exposure. Synergism between ultrasound and x-rays has been observed.

6.0068, INTRAMETROPOLITAN RESIDENTIAL MOBILITY
M.D. VANARSDOL, Univ. of Southern California, Graduate School, *Los Angeles, California* 90007

The objectives of this research on intrametropolitan residential mobility are: to determine the effects of past and present residences upon subsequent mobility plans, choices and behaviors; to specify the social and psychological factors which interact with residence histories to generate mobility attitudes and behaviors; to specify how changes in urban environments influence mobility patterns. The data for this research includes interviews obtained in 1961 and 1962, census information, and information on environmental hazards in the Los Angeles-Long Beach, and the Anaheim-Garden Grove-Santa Ana Standard Metropolitan Statistical Area. The interview data includes residence history, information on the family life cycle and familism, social mobility and aspirations, perceptions of the residential environment and residence needs and aspirations, social and locality participation. Neighborhood characteristics of population and housing are available from census tapes. Environmental hazards data include information on brush fires, floods and slides, air pollution, air traffic noise, and juvenile delinquency. Thus, the researchers will be able to integrate demographic, ecological and social psychological perspectives in the study of metropolitan residential mobility.

6.0069, PHYSIOLOGICAL AND PSYCHOLOGICAL ADJUSTMENT TO NOISE
K.D. KRYTER, Stanford Research Institute, *Menlo Park, California* 94025

The major objective of the study is to determine to what extent persons, of somewhat different personality 'types', physiologically and psychologically adapt over several months to near daily exposures to various steady-state and intermittent background noise. The effect of the noises upon the learning and performance of certain mental tasks will also be studied. The results of the studies should contribute valuable information for the estimation of the present or potential detrimental effect, if any, of environmental noise upon the mental health and general well-being of people.

6.0070, NOISE INDUCED DEAFNESS - MASKING AND SPEECH PERCEPTION
K.D. KRYTER, Stanford Research Institute, *Menlo Park, California* 94025

The general objective is the understanding of the performance characteristic of the normal human ear and the ear that suffers from hearing loss, primarily noise-induced deafness. The principal research approaches to be used to meet this objective are: 1. To study and explore, by means of perceptual tests, under controlled laboratory conditions, the relative capacities of the normal and deafened ear to detect and discriminate simple and complex acoustical signals. The tests will be disigned to define and delineate most probable underlying neuro-physiological mechanisms involved in such discriminations in the normal and deafened ear. 2. To study the ability of persons with normal hearing and persons with deafness to understand speech that has been narrow-pass-band filtered and processed in various ways. It is hypothesized that the speech may be made more understandable to the deafened ear as the result of processing and 'packaging' the speech signal in either or both the frequency-amplitude and time domains in ways that might best match the remaining performance characteristics of the deafened ear. 3. To test and evaluate the knowledge gained in the proposed research for the alleviation of hearing loss sustained in industry and elsewhere due to exposure to excessive noise.

6.0076, SURVEY OF EXISTING FEDERAL, STATE AND LOCAL NOISE CONTROL ORDINANCES
L.H. MAYO, George Washington University, Prog. of Pol. Stud. Sci. Tech., *Washington, District of Columbia* 20037 (68-04-0032)

The work shall be performed as follows: A. Collect and systematize relevant legal data, categorizing existing laws or regula-

tions as follows. 1. Level of government enacting or promulgating laws or regulations. 2. Authority for the enactment. 3. Source of or nature of noise covered by law or regulation. 4. Standards or criteria prescribed in the law or regulation. 5. Categories of persons, organizations, industries, common carriers, activities, or places covered by or subject to the law or regulation. 6. Liability or penalties provided. 7. Mode or manner of enforcing the standards prescribed. B. Analyze existing legal framework for noise abatement and control including the following key factors: 1. Legality of existing laws and regulations. 2. Uniformity or lack thereof in legal treatment of noise problems. 3. Gaps in legal coverage of existing noise sources which are social intrusions that can be reduced or eliminated. 4. Ambiguities and weaknesses in existing legal structure, particularly with regard to noise standards and their relationship to noise measurements. 5. Relationship of standards and remedies to 'unquantified environmental amenities and values' referred to in Section 102 (2) (B) of the National Environmental Policy Act of 1969, Public Law 91-190. 6. Degree to which particular statutory or regulatory schemes treat a particular source of objectionable noise without reference to all sources contributing to environmental noise level.

C.E. WILLIAMS, U.S. Navy, Aerospace Medical Res. Lab., *Pensacola, Florida* 32512

Technical Objective: Optimize speech communications in naval aviation acoustical environments and to develop acoustical analysis techniques for detecting psychological and physiological stress in the speech of naval aviation personnel.

SUPPORTED BY U.S. Dept. of Defense - Navy

6.0080, BEHAVIORAL TOXICITY OF NOISE IN IMMATURE MICE

W.B. ITURRIAN, Univ. of Georgia, School of Pharmacy, *Athens, Georgia* 30601

Immature mammals are notoriously more sensitive than adults to infections (e.g., rubella induced deafness), certain drugs (e.g. Thalidomide induced phocomelia) and several poisons. Recent reports (Iturrian and Fink, 1967; Iturrian, 1969) add noise to the list of environmental factors having dramatic deleterious effects upon the growing animal but produce a mild reaction in the adult. We demonstrated that mice considered to be resistant to audiogenic seizures become uniformly audio-sensitive if subjected to a single sensitizing sound stimulus (95 db doorbell for 30 sec.) at a critical age (age 15-22 days for CF-1). Additional factors dramatically affecting audio- sensitization include (1) the interval in days between the initial and second (test sound); (2) the duration of the initial (sensitizing sound); (3) the physical characteristics of the stimulus, most importantly the frequency range; and (4) extraneous environmental noise. (Iturrian, 1969).

The objectives of this exploratory proposal are to: (1) standardize more completely the procedure and occurrence of audiosensitization; (2) assess the relative potential of environmental noises such as sonic boom and flight noise of the new large transport turbojects to induce audio-sensitivity and/or to alter the temporal parameters of audio-sensitization; and (3) to assess the effects of such environmental noise upon pesticide toxicity, drug effectiveness and behavioral responses of immature mice.

6.0081, INTERACTION OF ULTRASOUND AND BIOLOGICAL MEDIA

F. DUNN, Univ. of Illinois, School of Engineering, *Urbana, Illinois* 61801

The ultrasonic thresholds for irreversible functional and histological changes in the mammalian central nervous system are to be determined as a function of frequency, acoustic intensity, pulse length, and temperature. The lumbar enlargement of the spinal cord of young mice will be used to study the functional changes and the adult cat brain will be employed to study the histological changes. The results of this study will establish safe operating conditions for the clinical employment of ultrasound as a diagnostic tool and is expected to aid in the elucidation of the physical mechanisms of interaction of ultrasound and tissue.

SUPPORTED BY U.S. National Science Foundation

6.0082, ULTRASONIC ABSORPTION BY BIOLOGICAL MATERIALS

F. DUNN, Univ. of Illinois, School of Engineering, *Urbana, Illinois* 61801

Ultrasound employed as an agent in medical diagnosis and theerapy and as an experimental tool for analysis of biological systems continues to receive ever increasing attention. However, relatively little is known and understood of the physical mechanisms of interaction of ultrasonic waves and biological media. An important adjunct to the elucidation of the fundamental physical mechanisms is a deep insight into the absorption processes and this research is addressed to these questions.

The ultrasonic absorption coefficient is determined in tissue structures in vivo by the transient thermoelectric method. Absorption measurements are made as a function of frequency, temperature, hydrostatic pressure, concentration, type of solvent and wave amplitude.

6.0084, HEARING AND VOCAL OUTPUT
C.I. BERLIN, Louisiana State University, School of Medicine, *New Orleans, Louisiana* 70112

Hearing and vocal output in normal, hard-of-hearing, and deaf mice are being studied. Evoked cortical potential, cochlear potential, and single unit recordings are being used as measures of auditory function. Findings to date show a peak vocalization during distress which is directly related to the auditory sensitivity curve. Studies of ultrasonic vocalization in infant mice and rats have shown to date that these are not specifically attractants for mother rodents. However, in the course of this study, major auditory differences between feral and laboratory mice have been uncovered.

6.0087, RESPONSE OF CAGED MINK TO SONIC BOOM
J.R. MENEAR, U.S. Dept. of Agriculture, Agricultural Engin. Res. Div., *Beltsville, Maryland* 20705 (214-024-B317)

OBJECTIVE: Determine the effects of sonic boom on production of caged mink.

APPROACH: Determine instrumentation requirements for measuring sonic boom over-pressures, and associated structural vibrations, in typical mink housing; coordinate measurement technique with boom propagation by Air Force units. Assemble, test, and calibrate a complete instrument system for field use. Coordinate electric power requirements for these instruments and those used by other units during tests. Operate system during tests; determine necessary corrections in flight conditions to approach specified over-pressures. Calibrate and test a sonic boom simulator to produce over-pressures equal to previous booms; operate simulator and instrument system during tests with simulated booms. Analyze over-pressure and vibration data to determine intensity of significant variable. Report procedure and results, and cooperate with other units in reporting entire experiment.

6.0089, SYSTEMS STUDY OF HELICOPTER NOISE REQUIREMENTS
R.W. SIMPSON, Mass. Inst. of Technology, Graduate School, *Cambridge, Massachusetts* 02139 (DAHCO4)

Technical Objective: To establish a new methodology for systems analysis which includes noise criteria and to develop a new wind tunnel facility for making useful noise measurements on V/STOL aircrafts types. It is important for the Army to reduce the noise levels of its helicopters so that the missions of surveillance, reconnaisance and target acquisition can be performed better, without giving too much warning of approach to the Army. The mission accomplishment may still be performed better if just the right combination of noise reduction and performance of the helicopter existed. The question that remains unanswered is- what is the most desirable combination of these parameters so the mission effectiveness will be maximized. This project is aimed towards answering this question.

SUPPORTED BY U.S. Dept. of Defense - Army

6.0090, THE DETERMINATION OF SUSCEPTIBILITY TO HEARING LOSS
W.D. WARD, Univ. of Minnesota, School of Medicine, *Minneapolis, Minnesota* 55455

This research will examine in the chinchilla the relations among (1) the temporary changes in auditory sensitivity caused by severe but subtraumatic exposures to noise, (2) the permanent changes in sensitivity produced by a more severe noise exposure, and (3) the structural and ultrastructural changes observed in the affected cochleae. Behavioral testing is accomplished by means of conditioned- avoidance techniques. Particular attention will be paid to possible histological sequelae of noise exposure that are not associated with a loss of auditory sensitivity. The fundamental question, however, is: Can individual differences in temporary effects of noise be used to predict individual differences in resistance to permanent effects from more severe exposures?

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

6.0091, STUDY OF THE EFFECT OF NOISE ON HUMANS
J. MILLER, Central Inst. for the Deaf, *Saint Louis, Missouri*

This is a study and compilation of the known effects of noise on humans. A comprehensive description of all major known physiological and psychological effects will be presented, along with an indication of possible effects.

6.0092, THE EFFECTS OF AGE, FOOD DEPRIVATION, AND WHITE NOISE ON READINESS TO EAT AND EXPLORATORY TENDENCIES IN RATS
L.F. JAKUBCZAK, U.S. Veterans Administration, Hospital, *Saint Louis, Missouri* 63125

The purposes of this experiment were (1) to test the generality of an earlier finding; (2) to determine whether or not there were age differences in the effects of noxious stimulation on readiness to eat in rats under moderate and high levels of food deprivation and; (3) to determine the role played by age differences in exploratory tendencies (if any) in age differences in readiness to eat (if any).

A 3x2x2 experiment was run, consisting of three age groups of rats (2, 11, and 24 months old), two levels of acute food deprivation (24, 96), and two levels of aversive stimulation (ambient vs white noise). The dependent variables were readiness to eat (Bolles, 1965) and the frequency of exploratory behavior admitted during the first three minutes of the test (deLorge and Bolles, 1961). Preliminary analysis of the data indicates that the main effects of duration of food deprivation and of age were significant but the effects of aversive stimulation on readiness to eat was not. The results are consistent with those of Bolles in that with increasing age there was a decreasing readiness to eat at a

given level of food deprivation. Thus the original inconsistency between the Bolles' results and those of Jakubczak are probable due to differences in methodology.

Manuscript in preparation for publication in the Journal of Gerontology.

6.0093, STUDIES IN COMPARATIVE AUDITORY NEUROPHYSIOLOGY

N. SUGA, Washington University, School of Arts, *Saint Louis, Missouri* 63130

Studies on neural mechanisms of hearing and sensory mechanism in the lateral line system are to be carried out by recording single unit activity from both the peripheral and central nervous systems with microelectrodes. The following points will be investigated: 1) transducer and gating mechanisms in receptors, 2) integration in and among auditory neurons, 3) specialization of single auditory neurons to pure tones, FM sounds, and noise bursts (three basic components in communication sounds of various animals, including human), 4) biosonar systems, 5) environment sensing with electro receptors, 6) species- specificity (or evolution) in information processing, 7) neural basis of psycho-acoustic phenomena, 8) control of auditory information processing and modification of usage of auditory information by higher auditory centers or other sensory systems or condition of an animal, and 9) neural-modeling. The use of a variety of animals is emphasized.

The project will contribute to the basic understanding of the neural mechanisms of hearing in animals, including man, and may lead to practical advances in environment sensing by the blind.

SUPPORTED BY U.S. National Science Foundation

6.0094, COMFORTABLE LISTENING LEVELS FOR NOISE

W. HILL, U.S. Veterans Administration, Hospital, *Bronx, New York* 10468

The purpose of the present investigation was to examine Most Comfortable Loudnss (MCL) for four noise stimuli. Using a modified Bekesy audiometer, the effects of the following variables on MCL were investigated: (1) attenuation rate (a fast attenuation rate of 2.5 dB/sec. versus a slow attenuation rate of 1.25 dB/sec.); (2) four noise stimuli (white noise and narrow bands of noise centered at the frequencies 500 Hz, 1000 Hz and 2000 Hz); (3) method of subject response (a conventonal Bekesy response switch versus a modified Bekesy response switch); (4) subject sex (male versus female); and (5) variability over time (session one and session two).

Thirty-two male and 32 female subjects participated in the investigation. All subjects possessed hearing sensitivity within normal limits, and had no prior experience with Bekesy audiometry or prior experience in an experiment involving listening behavior. One half of the subject sample (16 males and 16 females) tracked MCL using the conventional response switch, and the other half tracked MCL using the modified response switch. Each subject tracked MCL for 90 seconds for each of eight experimental conditions.

For the conventional response record, each peak and each trough was measured and recorded. These levels were averaged across each 90 second period. When using the modified response switch, each MCL level chosen by a subject was shown by a horizontal line. These levels, as with the levels recorded for the conventional trackings, were averaged across each 90-second period. The main statistical treatment of these data was a repeated measures factorial analysis of variance procedure.

Within the limitations of the investigation, the following conclusions were proposed: (1) Most comfortable loudness (MCL) varies significantly as a function of the type of noise stimulus used. (2) Attenuation rate should be considered as an important variable in the measurement of MCL. (3) MCL for noise has low intra-subject variability, but relatively high inter-subject variability. It cannot be assumed that the level averaged for all subjects is most comfortable for all people. Each person's MCL must be measured independently, for there is no apparent way to predict MCL based on threshold information, or on the results of the present investigation.

SUPPORTED BY U.S. Veterans Administration

6.0095, EFFECTS OF SONIC BOOM ON MINK

H.F. TRAVIS, U.S. Dept. of Agriculture, Fur Animal Experiment Station, *Ithaca, New York* 14850 (033401421433)

OBJECTIVE. Study the effects of sonic boom on reproduction and behavior of farm-raised minks.

APPROACH. Expose pregnant and nursing mink to booming devices developed for the national sonic boom evaluation program. Research will be conducted to determine critical indications of possible harmful effects which can be attributed to sonic boom during gestation, parturition, whelping and early postnatal development.

PROGRESS. Claims amounting to over 3/4 million dollars have been filed against the U. S. Air Force by mink farmers for alleged damage to mink from sonic booms during the reproductive season. During the calendar year 1970 a sonic study is being conducted in Petersburg, Alaska in cooperation with the University of Alaska. Two hundred adult females and their progeny were boomed three times by USAF aircraft on May 11 with booms of 6 pounds per square foot overpressure. On the date of booming 41% of the females had whelped. On the following day 120 adult females and their young at a different site were boomed with a N.A.S.A. simulator with booms of approximately the same magnitude. Two hundred adult females and their young at a third site were used as controls. Thirty male and 30 female kits from each group will be raised to pelting (Nov. 1970). Evaluation will be by reproductive performance, kit mortality, kit growth, pelt quality, and histological analysis of organs related to stress.

6.0097, COMPARATIVE STUDY OF VOCAL LEARNING

P.R. MARLER, Rockefeller University, Graduate School, *New York, New York* 10021

Man is the only primate known to be capable of vocal imitation. Only among birds do we find recurrence of the same capability. Previous work has established that vocalizations of certain birds are transmitted by learning in nature. The processes underlying avian vocal development are the subject of the present research request, with special reference to critical periods during life at which learning occurs most readily, and to the ontogenetic importance of the bird's ability to hear its own voice. Pilot experiments show that bilateral removal of the cochlea results in abnormal vocal development in canaries. Birds raised in high level white noise until their singing behavior had fully matured showed a pattern of singing behavior when the noise was turned off which resembled that of deaf birds. Some of the abnormalities were subsequently corrected. We now propose a more detailed study of the effects of surgical deafening and exposure to a masking sound at various ages on subsequent song development in canaries. In a parallel series of experiments, the redwinged blackbird has been found suitable for studies on song development. Males raised in isolation from 6 days of age develop songs which are normal in some respects, though they differ in detail from the patterns found in the population from which they came. Playback of recorded songs from 40 to 70 days of age for one hour per day in two individuals resulted in learning. In more detailed study of development in this species, birds will be trained at different ages to see whether there is a critical period for learning. Effects of surgical deafening will also be explored in birds deafened both early in life, and later, after training with playback of recorded songs has occurred. In this way we propose to test the hypothesis that hearing is important in song development, not only for the bird to hear sounds from the environment, but also for it to hear its own voice during development.

6.0100, EFFECTS OF AIR FORCE NOISES ON POPULATIONS SURROUNDING AIR BASES
G. ROSINGER, Battelle Memorial Institute, *Columbus, Ohio* 43201 (F33615-71-C-1288)

Technical Objective: Aviation noise environments generate well defined physiological responses and little defined psychological responses of people. The objective is to investigate in the laboratory the acceptability of specific approaching versus receding aircraft noises, and accompanying physiological responses that may occur. Approaching noises are much less acceptable than non approaching sounds, yet this difference has not been quantified. This effort will quantify the psychological judgments of acceptability and identify the presence or absence of simultaneous physiological changes. Results will be utilized in the revision and updating of land use planning documents for Air Force installations.

6.0101, RESEARCH ON PERMANENT AND TEMPORARY SHIFTS IN HEARING THRESHOLD PRODUCED BY EXPOSURE TO AIR FORCE NOISE
D.J. LIM, Ohio State University, School of Medicine, *Columbus, Ohio* 43210 (F33615-71-C-1461)

Technical Objective: AF function - to insure safety and unimpaired performance of AF personnel in hostile noise environments. Deficiency - insufficient criteria to establish a practical protection system. Research - use both animals and man in noise environments and obtain essential data. How research contributes - establishes noise levels for minimum detectable damage and describes mechanism of damage. There is a need to study the response of the nervous system to the stresses that are expected to occur in aerospace environments in order to determine the fundamental principles for establishing protective devices and techniques to insure safety and unimpaired performance of the nervous system. Investigation is needed on the problem of excessive noise reducing the effectiveness of our speech communications. Present Air Force operational situations require personnel to be exposed to sound environments for extended periods, in excess to the normal eight-hour working day. After exposure to moderate sound for a long time there is a loss in hearing. A thorough knowledge of the biochemical activity and anatomical changes within the inner ear is essential to making intelligent judgments on possible methods to combat this loss.

6.0102, AUDITORY RESPONSES TO ACOUSTIC ENERGY EXPERIENCED IN AIR FORCE ACTIVITIES
H.C. SOMMER, U.S. Air Force, Aerospace Med. Res. Lab. 6570, *Dayton, Ohio* 45433

Technical Objective: To examine various characteristics of human hearing such as resistance to noise, temporary hearing loss, recovery from hearing loss, relative effects of frequency, intensity, duration and intermittency of hearing loss, high frequency hearing (above 8000 HZ), and long term level effects in order to establish general principles of behavior of the human ear in noise. To determine the potential hazard of specific Air Force problem noise environs and provide means for minimizing or eliminating these effects. One of the most prevalent and serious effects of noise in Air Force operations is over exposure of the human auditory system, resulting in impairment of hearing. Effective preventive and control measures must be based upon the definition and understanding of the functioning of the human auditory system in the presence of noise. This work is related to the infrasound program and assessment of damage risk criteria for infrasound.

6.0104, PSYCHOLOGICAL AND PHYSIOLOGICAL ADAPTATION TO SIMULATED SONIC BOOMS - PHASE I
W.E. COLLINS, U.S. Dept. of Transportation, Civil Aeromedical Institute, *Oklahoma City, Oklahoma*

Based on the recommendation of the Human Response Panel, a laboratory study will be undertaken using a model of the sonic boom simulator developed for NASA at the Stanford Research Institute. Three groups of six male subjects each will be tested; one group will be in the 21-25 year age-range; a second group will be in the 40-45 year age- range, and the third will be in the 60-70 year age-range. Subjects will spend 3-4 weeks (20-28 consecutive days) in the study. The first 5-7 days will be an environmental adaptation period (no booms). During the next 10-14 days, subjects will be exposed to 8 booms nightly. All booms will be 0.9 psf and will be sounded hourly from 2300 hours through 0600 hours. The final 5-7 days will be used to examine recovery effects (no booms). Continuous recordings will be made of EEG (brain wave activity), ECG (heart activity), eye movement, and EWL (evaporative water loss) throughout each night as indications of depth of sleep, stages of sleep, bodily changes, and fatigue. Subjects will also perform complex tasks on a special performance device at approximately 0700 hours and 1900 hours every day for a one-hour period to evaluate skilled performance. The tasks will involve such basic psychological, perceptual, and motor functions as vigilance, reaction time, monitoring, and mental performance. Subjects will be free to conduct their normal duties during the day but will not be permitted to sleep. The electrophysiological and the performance records will be analyzed to determine the influence of the booms on sleep, skills, bodily reaction, and behavioral changes. Appropriate statistical comparisons of pre- boom and post-boom phases will be made.

Tape recordings were made for the analysis of the boom characteristics produced by the CAMI device to assure that the

spectral components agree with those created by a true sonic boom. The first recordings obtained by Stanford Research Institute were not adequate for analysis; SRI representatives returned and took additional recordings on 28 January 1970. Results of the analyses were received on 5 March. Notification of acceptance of the simulator was made to the Contract Officer on 13 March.

6.0105, MOTOR PERFORMANCE UNDER SUDDEN STRESS - PHASE II
R.I. THACKRAY, U.S. Dept. of Transportation, Civil Aeromedical Institute, *Oklahoma City, Oklahoma*

Sudden, unexpected startling situations may cause a considerable disruption in performance and under extreme conditions can even result in temporary behavioral immobility or 'freezing.' The available information concerning pilot response times to sudden emergencies, such as near mid-air collisons, is extremely limited. In addition, little is known regarding the possible effects such 'emotional shocks' may have on subsequent control of the aircraft. Research directed toward this problem area would have relevance to selection of personnel by establishing those characteristics of subjects who demonstrate impaired performance under sudden stress. It would also provide information regarding the extent and duration of impairment under such conditions.

Performance impairment resulting from a sudden stress (startling) situation will be evaluated with simulated pilotry tasks (e.g., perceptual-motor tracking). Simulated sonic booms resulting from a sonic boom generator will serve as the startle stimuli. Different groups of subjects will be exposed to overpressure levels ranging from 0.9 to 4.0 pounds per square foot. Durations and rise times of the pressure waves will be held constant over groups. Concurrent physiological measures will include heart rate, respiration rate, and skin conductance. The physiological and performance data will be recorded on the CAMI Data Acquisition System and the converted results subjected to computer analysis.

Phase I demonstrated that an unexpected, startling, white noise stimulus resulted in a 65 percent increase in tracking error during the first five-second period following startle, with performance returning to pre-stimulus levels within 15 seconds following stimulation. Startle also produced comparable changes in heart rate.

The primary purpose of Phase II is to replicate the essential features of Phase I, using simulated sonic boons as the startle stimuli, and to compare these results with those obtained in Phase I.

6.0107, PENETRATIVE AND METABOLIC EFFECTS OF LOW INTENSITY ULTRASOUND IN NERVE AND MUSCLE WITH AND WITHOUT EXTERNALLY ADDED CORTISOL
J.E. GRIFFIN, Univ. of Pennsylvania, School of Medicine, *Philadelphia, Pennsylvania* 19104

In earlier work (1962, 1963, 1965) we studied ultrasonic movement of cortisol through swine skin and into paravertebral muscle and nerve, in situ, using standard duration of treatment for a small area but with higher intensity than some patients can tolerate. We wish to repeat these studies using intensities tolerable to all patients but for longer duration than has been used clinically to see if equivalent amounts of cortisol can be recovered.

One of the early studies (1965) indicated that 90 kc ultrasound has an effect on the metabolism of cortisol in untreated swine nerve. The standard 1 mc frequency does not. We wish to use a number of frequencies, ranging from 90 kc to 3.6 mc to determine whether there is a frequency controlled metabolism pattern in untreated nerve.

It is also desired to determine whether lidocaine hydrochloride and phenol can be so driven by ultrasonic energy. These agents are in current use for pain relief and reduction of muscle spasm, via hypodermic injection, but this cannot be done for all areas, because of the hazard of paralysis. There is at present no method of quantitation specific for lidocaine or phenol in biologic material. A method of recovery will have to be devised.

6.0108, BIOCHEMICAL CORRELATES IN ENVIRONMENTAL STRESS
H.H. SMOOKLER, Univ. of Pittsburgh, School of Medicine, *Pittsburgh, Pennsylvania* 15213

Environmental stressors consisting of noxious audiogenic, visual and motion-type stimuli will be applied chronically on a randomized basis to rats and squirrel monkeys. Rats exposed to these stimuli for periods of ten to twenty weeks consistently develop hypertension. It has been demonstrated that alterations on the disposition of central and/or peripheral catecholamines is capable of preventing the induced hypertension. The proposed work will attempt to characterize the mechanisms by which central and peripheral adrenergic neurotransmitters modify the development of the hypertensive state. Since the maintenance of stress-induced hypertension is not completely dependent on a functional sympathetic nervous system, studies will be directed toward the possible involvement of adrenocortical hormones specifically with regard to their plasma binding, in vitro syntheses and in vivo secretion rates as a possible mechanism in the chronic phase of the hypertension. In addition, histopathologic analyses of adrenal cortex, kidney and cardiovascular system, and measurements of tissue electrolytes and plasma renin activity will be performed. Finally, stress studies will be undertaken utilizing squirrel monkeys to determine if hypertension can be developed in this species.

6.0111, THE EFFECTS OF NOISE ON BEHAVIOR
B.D. KAIMAN, U.S. Veterans Administration, Center, *Johnson City, Tennessee* 37684

Noise in our urbanized society has deleterious effects on humans. In Cohen's recent review (Cohen, A. Noise effects on health, productivity and well-being. Transactions of the New York Academy of Sciences, 68, 30, pp 910-918) a number of per-

tinent studies revealed this negative effect. However, exactly what the relationships are between noise and behavior is not clearly understood.

The purpose of this experiment is to determine the effects of moderate noise upon learning, longevity and body weights in the albino rat.

Subjects: 25 male and 25 female rats of the Sprague-Dawley strain will be obtained at weights of 125-150 grams (approximately 40 days old.) Apparatus: a white noise generator (Electronic Laboratories, Inc., Model E-1) and two speakers situated approximately near the center on each side of a standard rat cage rack (Wahmann).

Procedure: The rats will be maintained on an ad lib food and water schedule until every rat has died of natural cause. During this period they will be subjected to constant white noise at a moderate level. The cages will be rotated on the rack periodically to minimize any unequal exposure to the white noise. Every rat will be weighed at the onset of the experiment and then regularly until adult size and weight have been reached. A running record of the growth of each animal will be maintained, as well as longevity records. Standard psychological learning tasks (Skinner box, Y-maze) will be applied at varying intervals.

The learning measures, growth rates, and longevity records of the experimental subjects will be compared with the known averages of non- noise-bombarded rats, in order to deduce experimental effects.

6.0118, NEUROLOGICAL VARIABLES AFFECTING ULCERATION RATE

P.A. HORNBUCKLE, Virginia Commonwealth Univ., School of Arts, *Richmond, Virginia* 23219

Recent research by the present investigator and others has suggested a positive correlation between levels of neurological activity and rate of gastric ulceration in the rat where ulceration was induced by simple locomotor restraint. The object of the proposed study is to continue the investigation of this relationship by manipulating additional variables which are believed to influence neurological activity. Rats will be subjected to either lesions of the caudate nucleus or sham control lesions four days prior to 23 hours of locomotor restraint. Half of each of these groups will subsequently be restrained under either white noise or quiet sensory conditions. Since both noise and lesions of the caudate nucleus have been shown to increase neural activity via the reticular formation, it is expected that Ss with caudate lesions and Ss restrained noise conditions will show a higher frequency of ulceration than sham-controls or Ss restrained under quiet conditions.

spectral components agree with those created by a true sonic boom. The first recordings obtained by Stanford Research Institute were not adequate for analysis; SRI representatives returned and took additional recordings on 28 January 1970. Results of the analyses were received on 5 March. Notification of acceptance of the simulator was made to the Contract Officer on 13 March.

6.0119. STUDY OF THERMAL EFFECTS DUE TO PROPAGATION OF SOUND WAVES IN TISSUES

A.W. GUY, Univ. of Washington, School of Medicine, *Seattle, Washington* 98105

Purpose: The proposed research has as its initial objective the development of models for biological materials such as fat, muscles, and bones, which can describe the propagation and thermal effects of sound waves. The objective of this research is to study, with the development of these models the thermal effects of sound waves in layered biological material.

There are three aspects of this program of research that must be developed in parallel: 1. Theoretical studies to determine a model of propagation which explains data available. 2. Measurements in tissues and other biological materials to determine the adequacy of the proposed models. 3. Construction of analogs which simplify the measurements. As usual, simple models are chosen initially; then they are compared with available data or experimental results. Limitations and range of applicability of the models are determined; then these models can be refined to extend the range of applicability and to take into account possible anomalies detected during the experimental studies. 4. An interesting phenomenon that could be evaluated in these studies is the excitation of piezoelectric currents in bone due to ultrasound waves. This opens up the interesting possibility of possible interaction between ultrasound waves and electromagnetic waves.

Significance and Relationship to Rehabilitation: Past investigations on ultrasound as a thereapeutic tool were mostly experimental. No control over this tool has ever been developed. A systematic theoretical investigation of the heat generation by ultrasonic waves propagating in biological materials will assist in the research of optimized frequencies of the sound wave for therepeutic heating and improve the design of applicators.
